Introduction to ANSYS FLUENT

Lecture Theme:

All CFD simulations follow the same key stages. This lecture will explain how to go from the original planning stage to analyzing the end results

Learning Aims:

You will learn:

The basics of what CFD is and how it works

The different steps involved in a successful CFD project

Learning Objectives:

When you begin your own CFD project, you will know what each of the steps requires and be able to plan accordingly

What is CFD?

Computational Fluid Dynamics (CFD) is the science of predicting fluid flow, heat and mass transfer, chemical reactions, and related phenomena.

To predict these phenomena, CFD solves equations for conservation of mass, momentum, energy etc..

CFD is used in all stages of the engineering process:

- Conceptual studies of new designs
- Detailed product development
- Optimization
- Troubleshooting
- Redesign

CFD analysis complements testing and experimentation by reducing total effort and cost required for experimentation and data acquisition

How Does CFD Work?

ANSYS CFD solvers are based on the finite volume method

- Domain is discretized into a finite set of control volumes
- General conservation (transport) equations for mass, momentum, energy, species, etc. are solved on this set of control volumes

$$\underbrace{\frac{\partial}{\partial t} \int_V \rho \phi dV}_{\text{Unsteady}} + \underbrace{\oint_A \rho \phi \mathbf{V} \cdot d\mathbf{A}}_{\text{Convection}} = \underbrace{\oint_A \Gamma_\phi \nabla \phi \cdot d\mathbf{A}}_{\text{Diffusion}} + \underbrace{\int_V S_\phi dV}_{\text{Generation}}$$

- Partial differential equations are discretized into a system of algebraic equations
- All algebraic equations are then solved numerically to render the solution field

Equation

Equation	ϕ
Continuity	1
X momentum	u
Y momentum	v
Z momentum	w
Energy	h

- FLUENT control volumes are cell-centered (i.e. they correspond directly with the mesh) while CFX control volumes are node-centered**

Step 1. Define Your Modeling Goals

What results are you looking for (i.e. pressure drop, mass flow rate), and how will they be used?

What are your modeling options?

- What simplifying assumptions **can you make** (i.e. symmetry, periodicity)?
- What simplifying assumptions do you **have to make**?
- What physical models will need to be included in your analysis

What degree of accuracy is required?

How quickly do you need the results?

Is CFD an appropriate tool?

Step 2. Identify the Domain You Will Model

How will you isolate a piece of the complete physical system?

Where will the computational domain begin and end?

- Do you have boundary condition information at these boundaries?
- Can the boundary condition types accommodate that information?
- Can you extend the domain to a point where reasonable data exists?

Can it be simplified or approximated as a 2D or axi-symmetric problem?

Step 3. Create a Solid Model of the Domain

How will you obtain a model of the *fluid* region?

- Make use of existing CAD models?
- Extract the fluid region from a solid part?
- Create from scratch?

Can you simplify the geometry?

- Remove unnecessary features that would complicate meshing (fillets, bolts...)?
- Make use of symmetry or periodicity?
 - Are both the flow and boundary conditions symmetric / periodic?

Do you need to split the model so that boundary conditions or domains can be created?

Original CAD Part

Extracted Fluid Region

Step 4. Design and Create the Mesh

What degree of mesh resolution is required in each region of the domain?

- Can you predict regions of high gradients?
 - The mesh must resolve geometric features of interest and capture gradients of concern, e.g. velocity, pressure, temperature gradients
- Will you use adaption to add resolution?

What type of mesh is most appropriate?

- How complex is the geometry?
- Can you use a quad/hex mesh or is a tri/tet or hybrid mesh suitable?
- Are non-conformal interfaces needed?

Do you have sufficient computer resources?

- How many cells/nodes are required?
- How many physical models will be used?

Step 5: Set Up the Solver

For complex problems solving a simplified or 2D problem will provide valuable experience with the models and solver settings for your problem in a short amount of time

For a given problem, you will need to:

- Define material properties
 - Fluid
 - Solid
 - Mixture
- Select appropriate physical models
 - Turbulence, combustion, multiphase, etc.
- Prescribe operating conditions
- Prescribe boundary conditions at all boundary zones
- Provide initial values or a previous solution
- Set up solver controls
- Set up convergence monitors

Step 6: Compute the Solution

The discretized conservation equations are solved iteratively until convergence

Convergence is reached when:

- Changes in solution variables from one iteration to the next are negligible
 - Residuals provide a mechanism to help monitor this trend
- Overall property conservation is achieved
 - Imbalances measure global conservation
- Quantities of interest (e.g. drag, pressure drop) have reached steady values
 - Monitor points track quantities of interest

A converged and mesh-independent solution on a well-posed problem will provide useful engineering results!

The accuracy of a converged solution is dependent upon:

- Appropriateness and accuracy of physical models
- Assumptions made
- Mesh resolution and independence
- Numerical errors

Step 7: Examine the Results

Examine results to ensure correct physical behavior and conservation of mass energy and other conserved quantities. High residuals may be caused by just a few poor quality cells.

Examine the results to review solution and extract useful data

- Visualization Tools can be used to answer such questions as:
 - What is the overall flow pattern?
 - Is there separation?
 - Where do shocks, shear layers, etc. form?
 - Are key flow features being resolved?
- Numerical Reporting Tools can be used to calculate quantitative results:
 - Forces and Moments
 - Average heat transfer coefficients
 - Surface and Volume integrated quantities
 - Flux Balances

Step 8: Consider Revisions to the Model

High residuals may be caused by just a few poor quality cells

Are the physical models appropriate?

- Is the flow turbulent?
- Is the flow unsteady?
- Are there compressibility effects?
- Are there 3D effects?

Are the boundary conditions correct?

- Is the computational domain large enough?
- Are boundary conditions appropriate?
- Are boundary values reasonable?

Is the mesh adequate?

- Can the mesh be refined to improve results?
- Does the solution change significantly with a refined mesh, or is the solution mesh independent?
- Does the mesh resolution of the geometry need to be improved?

Summary and Conclusions

Summary:

All CFD simulations (in all mainstream CFD software products) are approached using the steps just described

1. Define Your Modeling Goals
2. Identify the Domain You Will Model
3. Create a Solid Model of the Domain
4. Design and Create the Mesh
5. Set Up the Solver
6. Compute the Solution
7. Examine the Results
8. Consider Revisions to the Model

Remember to first think about what the aims of the simulation are prior to creating the geometry and mesh

Make sure the appropriate physical models are applied in the solver, and that the simulation is fully converged (more in a later lecture)

Scrutinize the results, you may need to rework some of the earlier steps in light of the flow field obtained

What Next:

Trainer will now demonstrate FLUENT in action
