- Some settings, such as ruler and axis visibility can also be controlled locally within a Fluent session (that is, outside of the **Preferences** dialog box). Settings that deviate from the global settings specified in the **Preferences** dialog box will not be retained beyond the current session.
- If you change a setting locally that is also controlled by **Preferences**, the local change will be shown for this session only. If you open the **Preferences** dialog box and click **Apply** in an attempt to overwrite the local settings change, the global setting will only appear if it is a change from how the setting is already specified globally. For example, if you have **Ansys Logo** set as **Black** in **Preferences**, then you change the logo to **White** in the **Display Options** dialog box, the logo will change from black to white. If you then re-open the **Preferences** dialog box and click **Apply**, the logo will remain white, even though it is

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

specified as **Black** in the preferences dialog box. The reason being that globally, the logo is already specified as black, so clicking **Apply** does not change the current global color of the logo, which is being overruled by your local change to white.

- Not all preference settings apply in all workspaces. For example, the **Flow Model** option in the **General** branch only applies to the **Solution** workspace and **Meshing Workflow** settings only apply to the meshing workflows in the **Meshing** workspace.

The controlling preferences file location is:

- Windows: `%HOMEDRIVE%%HOMEPATH%\.fluentconf\24.1.0\preferences`

  Note:

  If you have `%HOME%` is defined as an environment variable, then the preference location is `%HOME%\.fluentconf\24.1.0\preferences`

- Linux: `%HOMEPATH%/.fluentconf/24.1.0/preferences`

If no preference file is found (for instance, after installation of a new version or deletion of the preference file), Fluent will attempt to load user preferences from a previous version. If no previous version's preferences are found, Fluent will create a new file using the default settings.

*At any time, you can revert your preferences to the default settings by clicking the **Default** button in the **Preferences** dialog box. Or you can delete the preferences file and Fluent will follow the above rule to create a new one.*

1.4. Fluent Graphical User Interface Other Languages

You can have the Fluent graphical user interface appear in Japanese, Korean, or Chinese, by defining the appropriate environment variable before launching Fluent (you can define it in the **Environment** tab of the Fluent Launcher).

These are the environment variables for each language:

- `lang=ja` for Japanese
- `lang=ko` for Korean
- `lang=zh` for Chinese

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 1.28: Fluent GUI in Japanese

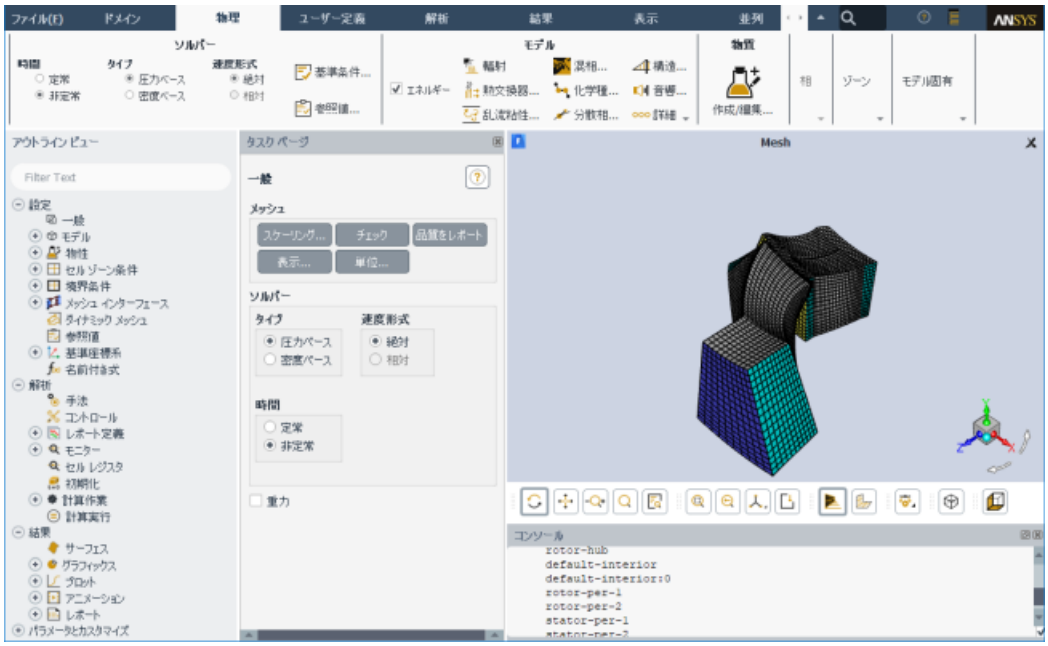

Figure 1.29: Fluent GUI in Korean

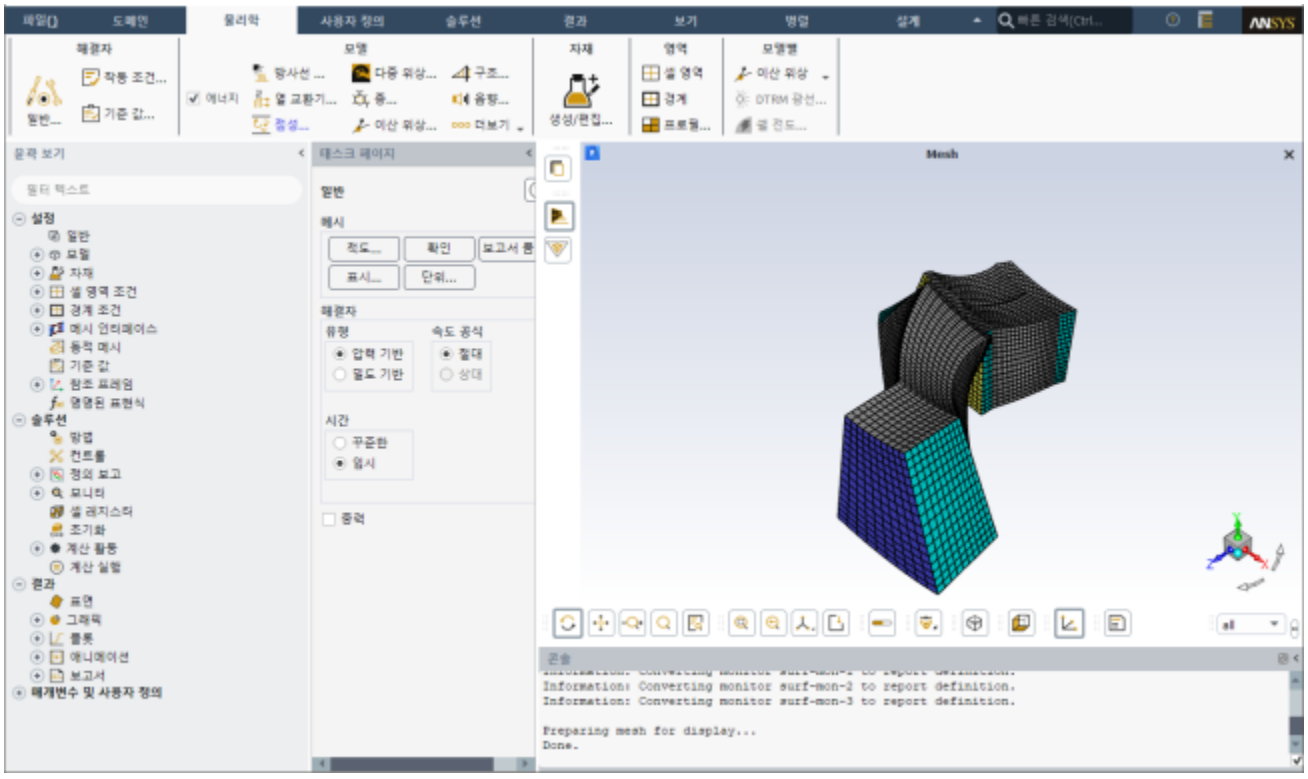

Figure 1.30: Fluent GUI in Chinese

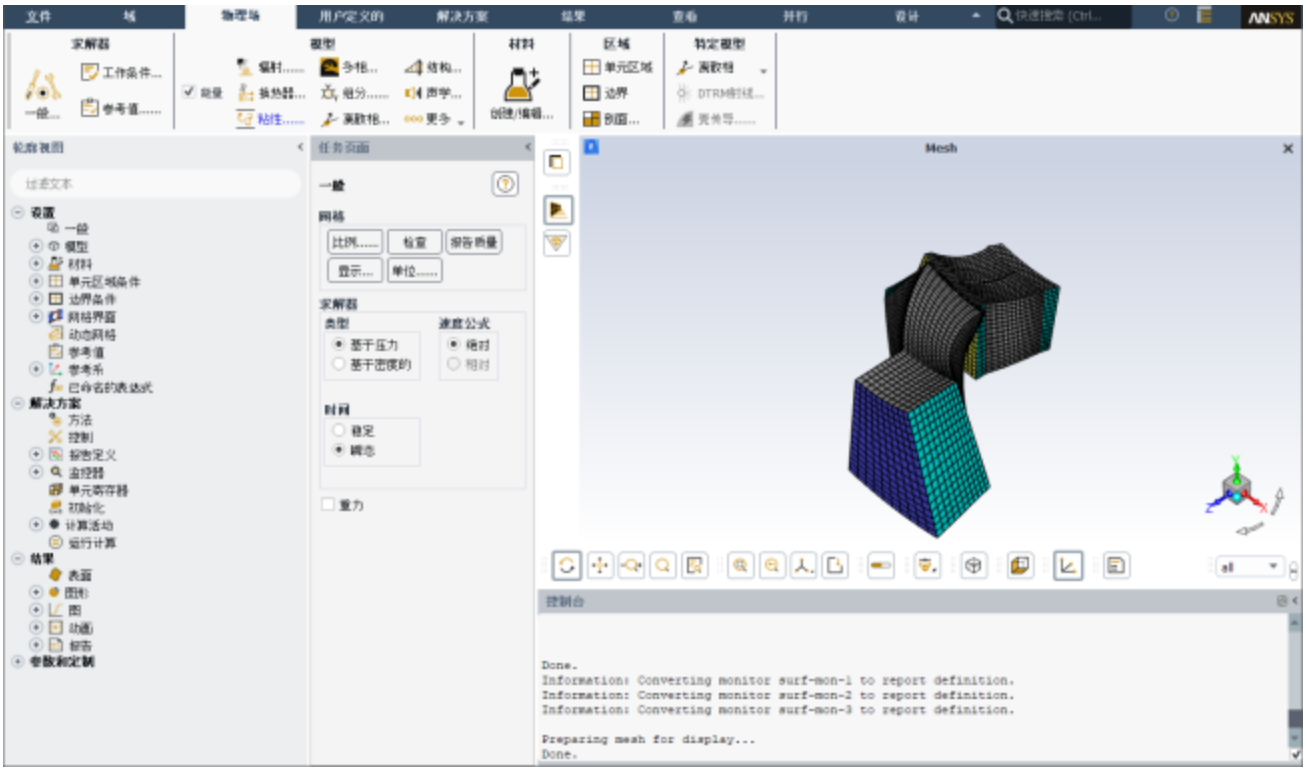


Limitations for Localization

Some areas of the Fluent 2024 R1 GUI are not completely translated including:

- Drop-down menu/list items
- Quick search results
- Pop up messages
- Graphics window titles and labels
- Object names (boundary conditions, graphics objects, and so on)
- Interface (GUI labels) for items without meaningful Japanese/Chinese/Korean equivalents, such as X, Y, Z, Cp, OK, and so on
- The Console

Important:

Localization of the Fluent workspaces is a Beta-level exposure, meaning that it has not been fully tested or validated. *The workspaces include Aero, Icing, Material Processing, and Post-Analysis (which is itself Beta level).*

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1.5. Having the Session Close After Sitting Idle

You have the option of enabling an idle timeout so that Ansys Fluent closes after a set period of sitting unused. This can be beneficial if an idle Fluent session is consuming computing resources that could be used elsewhere.

There are two ways to set an idle timeout:

- Set the timeout using the Figure 1.31: Set Idle Timeout Dialog Box (p. 917), as discussed in Timeout Using the Set Idle Timeout Dialog Box (p. 917)
- Set the timeout using the `FLUENT_MAX_IDLE_TIMEOUT` environment variable, as discussed in Timeout Using FLUENT_MAX_IDLE_TIMEOUT (p. 918).

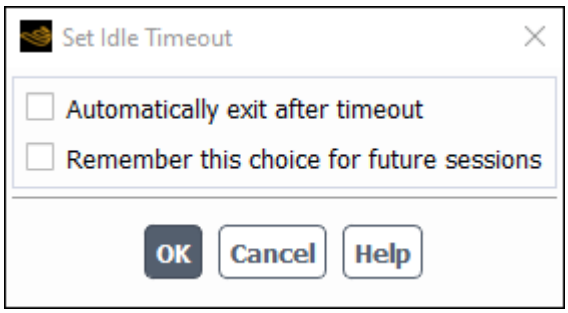
1.5.1. Timeout Using the Set Idle Timeout Dialog Box

Use the following steps to setup an idle timeout:

1. Open the **Set Idle Timeout** dialog box.

   File → Idle Timeout...

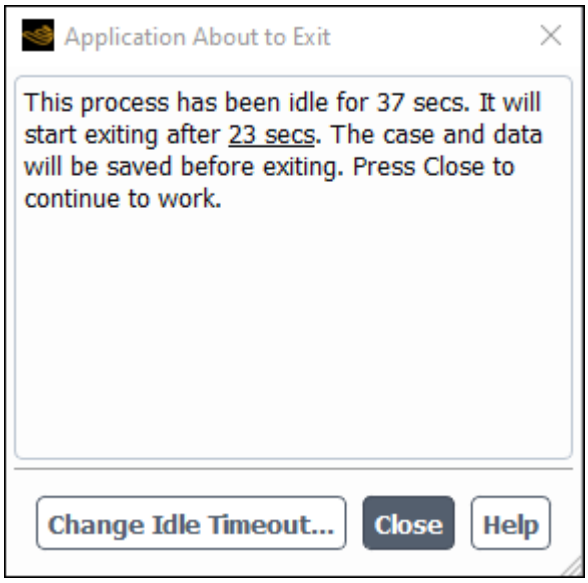
   Figure 1.31: Set Idle Timeout Dialog Box

2. Enable **Automatically exit after timeout**.
3. Enter how long you want Fluent to idle before closing in the **Idle timeout (min)** field. *Note that with five minutes remaining on the timer, the **Application About to Exit** dialog box opens, providing a count down to when Fluent will close. Before closing, Fluent saves case and data files in the working directory.*

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 1.32: Application About to Exit Dialog Box



4. (Optional) Enable **Remember this choice for future sessions** if you want to have the idle timeout set for future instances of Fluent. *Note that next time you open the **Set Idle Timeout** dialog box, **Remember this choice for future sessions** will not be enabled. All this option does is ask if you want to save settings for a future session as they are currently shown in the dialog box.*

1.5.2. Timeout Using FLUENT_MAX_IDLE_TIMEOUT

You can use an environment variable to set the idle timeout. The advantage of using `FLUENT_MAX_IDLE_TIMEOUT` is that you can specify a maximum timeout at an administrator level, so that individual users cannot increase the timeout beyond the maximum you define. This is useful for managing cluster/HPC resources where Fluent is typically run in batch mode.

Set `FLUENT_MAX_IDLE_TIMEOUT` equal to the maximum time, in minutes, that you want a Fluent session to sit idle before it exits. This environment variable should be defined on the system where the Fluent batch jobs are run (such as, a Linux cluster managed through a job scheduler).

1.5.3. Idle Timeout Limitations

There are a few limitations associated with the idle timeout feature:

- It is not available for Fluent Meshing except when Fluent Meshing is running from within Workbench.
- (Windows only) it is not compatible with launching Fluent in `-g` or `-gu` mode.

1.6. Using the Help System

Fluent includes an integrated help system that provides easy access to the program documentation. Through the graphical user interface, you have the entire User's Guide (p. 1) and other documentation available to you with the click of a mouse button. The Fluent User's Guide and other manuals are dis-

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

played on the Ansys help site, which allows you to use links and search tools and index tools to find the information you need.

There are many ways to access Ansys help. You can get reference information from within a task page or dialog box. You can also go to the User's Guide (p. 1) contents page and use the links to find the information you are looking for. In addition to the User's Guide (p. 1), you can also access the other Fluent documentation (for example, the Theory Guide or Fluent Customization Manual).

Note that the last two chapters of the User's Guide (Task Page Reference Guide (p. 4631) and Ribbon Reference Guide (p. 5293)) (p. 1) are also referred to as the Reference Guide, and contain a description of each task page, and dialog box.

The sections that follow provide information on how to get help for a task page or dialog box, and brief descriptions of the help menu items in Fluent.

1.6.1. Task Page and Dialog Box Help

1.6.2. Obtaining License Use Information

1.6.3. Version and Release Information

1.6.1. Task Page and Dialog Box Help

To get help about a task page or dialog box that you are currently using, click the **Help** button in the task page or dialog box. The help will open to the section of the User's Guide (p. 1) that explains the function of each item in the task page or dialog box. In this section, you will also find hypertext links to more specific section(s) of the User's Guide (p. 1) that discuss how to use the task page or dialog box and provide related information.

Note:

The latest versions of Google Chrome and Mozilla Firefox are recommended browsers for accessing Ansys Help. Microsoft Internet Explorer or Microsoft Edge are not supported.

1.6.2. Obtaining License Use Information

Your installation of Fluent is managed by the Ansys License Manager (ANSLIC_ADMIN). Information regarding the license being used is printed to the console. To learn more about Ansys licensing information, refer to the Licensing Documentation.

1.6.3. Version and Release Information

You can obtain information about the version and release of Fluent you are running by selecting the **Version...** option in help menu (accessed by clicking).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information
of ANSYS, Inc. and its subsidiaries and affiliates.

Chapter 2: Text User Interface (TUI)

The text user interface (TUI) in Fluent, also referred to as The Console (p. 896), is written in a dialect of Lisp called Scheme. Users familiar with Scheme will be able to use the interpretive capabilities of the interface to create customized commands. The text-based menu system provides a hierarchical interface to the underlying procedural interface of the program.

- You can easily manipulate its operation with standard text-based tools—input can be saved in files, modified using text editors, and read back in to be executed.
- The text menu system is tightly integrated with the Scheme extension language, so it can easily be programmed to provide sophisticated control and customized functionality.

A more complete description of the text-based interface, including a full list of commands is available in Fluent Text Command List.

Chapter 3: Reading and Writing Files

During an Ansys Fluent session you may need to import and export several kinds of files. Files that are read include mesh, case, data, profile, Scheme, and journal files. Files that are written include case, data, profile, journal, and transcript files. Ansys Fluent also has features that enable you to save pictures of graphics windows. You can also export data for use with various visualization and postprocessing tools. These operations are described in the following sections.

Important:

Ensure that you have read/write permission in the local user directory and that there are not any locked files in this directory, which could interfere with reading files into Ansys Fluent.

3.25. The .fluent File
3.26. Coupled Simulations in Ansys Fluent with Functional Mock-up Unit (FMU) Files

3.1. Shortcuts for Reading and Writing Files

The following features in Ansys Fluent make reading and writing files convenient:

- Automatic appending or detection of default file name suffixes
- Binary file reading and writing
- Automatic detection of file format (text/binary)
- Recent file list
- Reading and writing of compressed files
- Tilde expansion
- Automatic numbering of files
- Ability to disable the overwrite confirmation prompt
- Standard toolbar buttons for reading and writing files

For additional information, see the following sections:

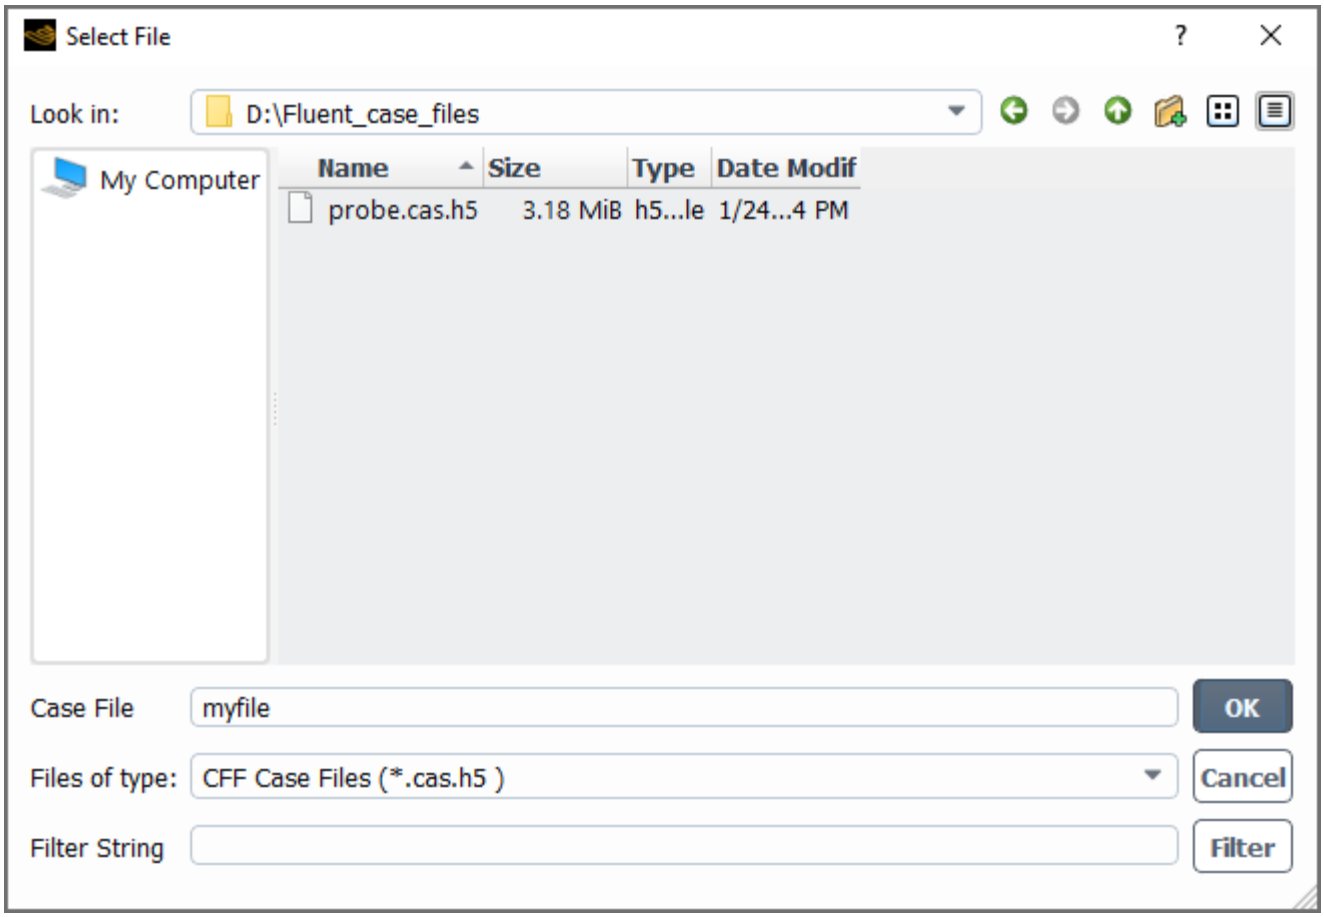
3.1.1. Default File Suffixes
3.1.2. Binary Files
3.1.3. Detecting File Format
3.1.4. Recent File List
3.1.5. Reading and Writing Compressed Files
3.1.6. Tilde Expansion (Linux Systems Only)
3.1.7. Automatic Numbering of Files
3.1.8. Disabling the Overwrite Confirmation Prompt

3.1.1. Default File Suffixes

Each type of file read or written in Ansys Fluent has a default file suffix associated with it. When you specify the first part of the file name (the prefix) for the commonly used files, Fluent automatically appends or detects an appropriate suffix. For example, to write a case file named `myfile.cas.h5` with the default settings, just specify the prefix `myfile` in the **Select File** dialog box (Figure 3.1: The Select File Dialog Box (p. 925)) and `.cas.h5` is automatically appended. Similarly, to read the case file named `myfile.cas.h5` into Fluent, you can just specify `myfile` and Ansys Fluent automatically searches for a file of that name with the suffix `.cas.h5`.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 3.1: The Select File Dialog Box



The default file suffix for case and data files, PDF (Probability Density Function) files, DTRM ray files, profiles, scheme files, journal files, and so on, are automatically detected and appended. The appropriate default file suffix appears in the **Select File** dialog box for each type of file. Note that for case, data, and mesh files, you can use the **Files of type** drop-down menu in the **Select File** dialog box to specify whether you want to read / write only the default CFF files or all formats (that is, both CFF and the legacy format); you can also change the order in which Fluent prioritizes these formats through the **Default Format for I/O** drop-down in the **Preferences** dialog box or through the `file/cff-files?` text command (for further details, see Reading and Writing Files in the Legacy Format (p. 934) and Reading Mesh Files (p. 929)).

3.1.2. Binary Files

When you write a case, data, or ray file, a binary file is saved by default. Binary files take up less memory than text files and can be read and written by Ansys Fluent more quickly.

Note:

You cannot read and edit a binary file, as you can do for a text file.

To save a text file, turn off the **Write Binary Files** option in the **Select File** dialog box when you are writing the file. Note that by default your case and data files will always be binary; if you require a

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

text file for a case or data file, you must write it in the legacy format (Reading and Writing Files in the Legacy Format (p. 934)).

3.1.3. Detecting File Format

When you read a case, data, mesh, PDF, or ray file, Fluent automatically determines whether it is a text (formatted) or binary file.

3.1.4. Recent File List

At the bottom of the **File/Read** ribbon tab submenu there is a list of four Ansys Fluent case files that you most recently read or wrote. To read one of these files into Ansys Fluent, select it in the list. This allows you to read a recently used file without selecting it in the **Select File** dialog box. If you want to change the number of recent files listed, you can change the **Number of files recently used** setting in the **Preferences** dialog box, which you can access by selecting **Preferences...** from the **File** ribbon tab.

Note that the files listed in this submenu may not be appropriate for your current session (for example, a 3D case file can be listed even if you are running a 2D version of Ansys Fluent). Also, if you read a case file using this shortcut, the corresponding data file is read only if it has the same base name as the case file (for example, `file1.cas.h5` and `file1.dat.h5`) *and* it was read/written with the case file the last time the case file was read/written.

Note:

Reading a case file from the **Recent Files** list in the Fluent Launcher will only load a case file and not the associated data file, even if the data file has the same base name and is stored in the same directory as the case file.

3.1.5. Reading and Writing Compressed Files

For more information, see the following sections:

3.1.5.1. Reading Compressed Files

3.1.5.2. Writing Compressed Files

3.1.5.1. Reading Compressed Files

You can use the **Select File** dialog box to read files (such as legacy mesh, case, and data files) that have been compressed using `compress` or `gzip`. If you select a compressed file with a `.Z` extension, Ansys Fluent automatically opens `zcat` to import the file. If you select a compressed file with a `.gz` extension, Fluent opens `gunzip` to import the file.

For example, if you select a file named `flow.msh.gz`, Fluent reports the following message indicating that the result of the `gunzip` is imported into Ansys Fluent via an operating system pipe.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
Reading "\"| gunzip -c \"Y:\flow.msh.gz\"\""...
```

Note:

In addition to `.gz` and `.Z` compression, Ansys Fluent can also handle `.bz2` compressed files.

Important:

- For Windows systems, only files that were compressed with `gzip` (that is, files with a `.gz` extension) can be read. Files that were compressed with `compress` cannot be read into Ansys Fluent on a Windows machine.
- Do not read a compressed ray file; Ansys Fluent cannot access the ray tracing information properly from a compressed ray file.

3.1.5.2. Writing Compressed Files

You can use the **Select File** dialog box to write a compressed file by appending a `.Z` or `.gz` extension onto the file name.

For example, if you enter `flow.gz` as the name for a legacy case file, Fluent reports the following message:

```
Writing "| gzip -cfv > Y:\flow.cas.gz"...
```

The status message indicates that the case file information is being piped into the `gzip` command, and that the output of the compression command is being redirected to the file with the specified name. In this particular example, the `.cas` extension is added automatically.

Note:

In addition to `.gz` and `.Z` compression, Ansys Fluent can also handle `.bz2` compressed files.

Important:

- For case and data files, such compression is not applied for the default Common Fluids Format (CFF), but instead the `.Z` or `.gz` extension is simply incorporated into the name (such as `.gz.cas.h5`). This compression is only used for the legacy format (such as when you have entered the following text command: `file/cff-files? no`).
- For Windows systems, such compression can be performed only with `gzip`. That is, you can write a compressed file by appending `.gz` to the name, but appending `.Z` does not compress the file.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Do not write a compressed ray file; Ansys Fluent cannot access the ray tracing information properly from a compressed ray file.

3.1.6. Tilde Expansion (Linux Systems Only)

On Linux systems, if you specify `~/` as the first two characters of a file name, the ~ is expanded as your home directory. Similarly, you can start a file name with `~username/`, and the `~username` is expanded to the home directory of "username". If you specify `~/file` as the case file to be written, Ansys Fluent saves the file `file.cas.h5` in your home directory. You can specify a subdirectory of your home directory as well: if you enter `~/cases/file.cas.h5`, Ansys Fluent saves the file `file.cas.h5` in the `cases` subdirectory.

3.1.7. Automatic Numbering of Files

There are several special characters that you can include in a file name. Using one of these character strings in your file name provides a shortcut for numbering the files based on various parameters (that is, iteration number, time step number, or total number of files saved so far), because you need not enter a new file name each time you save a file. (See also Automatic Saving of Case and Data Files (p. 934) for information about saving and numbering case and data files automatically.)

- For transient calculations, you can save files with names that reflect the time step number at which they are saved by including the character string `%t` in the file name. For example, you can specify `contours-%t.ps` for the file name, and Fluent saves a file with the appropriate name (for example, `contours-0001.ps` if the solution is at the first time step).

  This automatic saving of files with the time step number should not be used for steady-state cases, since the time step number will always remain zero.

- For transient calculations, you can save files with names that reflect the flow-time at which they are saved by including the character string `%f` in the file name. The usage is similar to `%t`. For example, when you specify `filename-%f.ps` for the file name, Fluent will save a file with the appropriate name (for example, `filename-005.000000.ps` for a solution at a flow-time of 5 seconds). By default, the flow-time that is included in the file name will have a field width of 10 and 6 decimal places. To modify this format, use the character string `%` *x* `.` *y* `f`, where *x* and *y* are the preferred field width and number of decimal places, respectively. Ansys Fluent will automatically add zeros to the beginning of the flow-time to achieve the prescribed field width. To eliminate these zeros and left align the flow-time, use the character string `%-` *x* `.` *y* `f` instead.

  This automatic saving of files with flow-time should not be used for steady-state cases, since the flow-time will always remain zero.

- To save a file with a name that reflects the iteration at which it is saved, use the character string `%i` in the file name. For example, you can specify `contours-%i.ps` for the file name, and Fluent saves a file with the appropriate name (for example, `contours-0010.ps` if the solution is at the 10th iteration).

- To save a picture file with a name that reflects the total number of picture files saved so far in the current Fluent session, use the character string %n in the file name. This option can be used only for picture files.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The default field width for `%i`, `%t`, and `%n` formats is 4. You can change the field width by using % *x* `i`, % *x* `t`, and % *x* `n` in the file name, where *x* is the preferred field width.

3.1.8. Disabling the Overwrite Confirmation Prompt

By default, if you ask Ansys Fluent to write a file with the same name as an existing file in that folder, it will ask you to confirm that it is "OK to overwrite" the existing file. If you do not want Fluent to ask you for confirmation before it overwrites existing files, you can use the **Batch Options** dialog box (for details, see Batch Execution Options (p. 204) in the Getting Started (p. 1) part of this manual). Alternatively, enter the `file/confirm-overwrite?` text command and answer `no` (see Text User Interface (TUI) (p. 921) for the text user interface commands).

3.2. Reading Mesh Files

Mesh files are created using the mesh generators (Ansys Meshing, the meshing mode of Fluent, Fluent Meshing, GAMBIT, GeoMesh, and PreBFC), or by several third-party CAD packages. From the point of view of Ansys Fluent, a mesh file is a subset of a case file (described in Reading and Writing Case Files (p. 932)). The mesh file contains the coordinates of all the nodes, connectivity information that tells how the nodes are connected to one another to form faces and cells, and the zone types and numbers of all the faces (for example, wall-1, pressure-inlet-5, symmetry-2).

The mesh file does not contain any information on boundary conditions, flow parameters. For information about meshes, see Reading and Manipulating Meshes (p. 1103).

To read a native-format mesh file (that is, a mesh file that is saved in the Ansys Fluent format, which includes FLUENT 5/6, Fluent/UNS, or RAMPANT meshes) into Fluent, use the **File/Read/Mesh...** ribbon tab item.

File → **Read** → **Mesh...**

Note that you can also use the **File/Read/Case...** ribbon tab item (described in Reading and Writing Case Files (p. 932)), because a mesh file is a subset of a case file. Ansys Meshing, the meshing mode of Fluent, Fluent Meshing, GAMBIT, GeoMesh, and PreBFC can all write a native-format mesh file. For information about these files and how they are created, see Ansys Meshing Mesh Files (p. 1125), Fluent Meshing Mode Mesh Files (p. 1125), Fluent Meshing Mesh Files (p. 1125), GAMBIT Mesh Files (p. 1126), GeoMesh Mesh Files (p. 1126), and PreBFC Mesh Files (p. 1126).

If after reading in a mesh file (or a case and data file), you would like to read in another mesh file, the Read Mesh Options Dialog Box (p. 5295) will open, where you can choose to

- Discard the case and read in a new mesh.
- Replace the existing mesh.

You also have the option to have the **Scale Mesh** dialog box appear automatically for you to check or scale your mesh, which in general is the recommended practice. For this to happen, enable **Show Scale Mesh Panel After Replacing Mesh**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

By default, when reading mesh files, Fluent uses the Common Fluids Format (CFF) which is built on the Hierarchical Data Format (HDF5). To read CFF files, use the ribbon tab item or text command and simply append `.msh.h5` to the file name.

Note:

In order to avoid changing preferences when reading mesh files, while using the **Select File** dialog box, as long as the file exists, Fluent will respect your choice of file regardless of the type that is selected for the **Files of type** field. Even if there is no explicit file type extension provided when specifying a mesh file, Fluent will initially look for a `.msh.h5` file type, followed by a `.msh.gz` file type, and finally a `.msh` file type.

CFF and HDF files are always binary and make use of built-in compression. Thus, they cannot be viewed in a text editor. However, third-party tools are available that enable you to open and explore the contents of files saved in HDF format.

You can read legacy mesh files (with the `.msh` extension) using one of the following options:

- When reading mesh files using the **File/Read/Mesh...** ribbon tab item, you can look for files written in the legacy mesh format by selecting **All Mesh Files (*.msh* *.MSH*)** from the **Files of type** drop-down list in the **Select File** dialog box.
- To read legacy mesh files in the current session, you can use the following text command: `file/cff-files? no`; to read legacy mesh files in the current and future sessions, open the **General** tab of the **Preferences** dialog box and select **Legacy** from the **Default Format for I/O** drop-down list. Note that both of these actions will also result in you reading and writing legacy case and data files.

For information on importing an unpartitioned mesh file into the parallel version of Fluent using the partition filter, see Using the Partition Filter (p. 4304).

For information about reading surface mesh files, see Reading Surface Mesh Files (p. 1138).

3.3. Reading and Writing Case and Data Files

Information related to the Ansys Fluent simulation is stored in both the case file and the data file. The commands for reading and writing these files are described in the following sections, along with commands for the automatic saving of case and data at specified intervals.

By default (that is, when the `file/cff-file?` text command is set to `yes`), the case and data files are written in the Common Fluids Format (CFF), which is built on the Hierarchical Data Format (HDF5). CFF files are always binary and make use of built-in compression. Thus, they cannot be viewed in a text editor. However, third-party tools are available that allow you to open and explore the contents of files saved in CFF / HDF.

You can specify the I/O mode and/or the CFF compression level through text commands:

```
>file/cff-options/compression-level
compression-level [0-9]? [1] 4

>file/cffio-options/io-mode
CFF I/O Modes:
 1. HOST
 2. NODE0
 3. PARALLEL INDEPENDENT
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
 4. PARALLEL COLLECTIVE
Enter Mode Number: [1] 2

NODE0 mode selected.
```

The compression level can be set from 0 (no compression; fastest) to 9 (maximum compression; slowest); the default level is 1. Note that increasing the compression level may not necessarily yield a corresponding decrease in file size.

The available I/O modes are:

1. `HOST`: I/O is done serially by the host process. This is the default mode when the file path is not accessible to compute-node 0.
2. `NODE0`: I/O is done serially by the node 0 process. This is the default mode when the file path is accessible to compute-node 0.
3. `PARALLEL INDEPENDENT`: I/O is done in a parallel file system using the independent mode of MPI I/O.
4. `PARALLEL COLLECTIVE`: I/O is done in a parallel file system using the collective mode of MPI I/O.

Note:

- The Parallel I/O modes do not support compression. If you have specified a non-zero level for compression and you switch to one of the parallel modes, the compression will be set to 0.
- For information on the supported parallel file systems (as well as specific configuration and usage issues), contact your Ansys Fluent support engineer.

When using the double-precision solver, you can specify that the data written in CFF data files is single precision (and thus sacrifice some precision in order to reduce the size of the files) by using the following text command prior to writing:

`file` → `cffio-options` → `single-precision-data?`

Important:

- If you adapt the mesh, you must save a new case file as well as a data file. Otherwise, the new data file will not correspond to the case file (for example, they will have different numbers of cells). If you have not saved the latest case or data file, Ansys Fluent will warn you when you try to exit the program.
- Note that if you define the time step size for a transient simulation and then subsequently read a data file that has a different value, the time step size will be overwritten with the value from the data file.

For additional information, see the following sections:

3.3.1. Reading and Writing Case Files

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3.3.2. Reading and Writing Data Files
3.3.3. Reading and Writing Case and Data Files Together
3.3.4. Reading and Writing Files in the Legacy Format
3.3.5. Automatic Saving of Case and Data Files

3.3.1. Reading and Writing Case Files

Case files contain the mesh, boundary and cell zone conditions, and solution parameters for a problem. It also contains the information about the user interface and graphics environment. The commands used for reading case files can also be used to read native-format mesh files (as described in Reading Mesh Files (p. 929)) because the mesh information is a subset of the case information.

Note:

Prior to reading in a case file, you can review some of the case properties to help ensure you are loading the intended file. The available summary includes the Fluent version that last saved the case, case precision and dimension, and the total number of cells, faces, and nodes. To preview the case information:

- From the Fluent Launcher: Select the case file and click **Case File Info**.
- From a running Fluent session: Use the **File**>**Read**>**Case/Mesh Info...** menu option and select the desired case file.

Select the **File/Read/Case...** ribbon tab item to open the **Select File** dialog box.

File → **Read** → **Case...**

Read a case file using the **Select File** dialog box. Note that the **Display Mesh After Reading** option in the **Select File** dialog box allows you to have the mesh displayed automatically after it is read.

Select the **File/Write/Case...** ribbon tab item to open the **Select File** dialog box.

File → **Write** → **Case...**

Write a case file using the **Select File** dialog box.

Note:

The working directory is automatically updated to the directory where the case file is written, when the writing is initiated from within the graphical user interface (writing using the `file/write-case` text command does not update the working directory). *You can determine the present working directory by entering pwd in the Console.*

When Ansys Fluent reads a case file, it first looks for a file with the exact name you typed. If a file with that name is not found, it searches for the same file with different extensions, prioritizing CFF files by default. When Ansys Fluent writes a case file, `.cas.h5` is added by default to the name you type.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In the single-precision version of Ansys Fluent, nodal coordinates are written by default in double precision, in order to ensure that there is no loss of precision if the case file is read back into the meshing mode. You can reduce the precision and case file size by using the following text command prior to writing:

`file → single-precision-coordinates?`

3.3.2. Reading and Writing Data Files

Data files contain the values of the specified flow field quantities in each mesh element and the convergence history (residuals) for that flow field.

1. After reading a mesh or case file, select the **File/Read/Data...** ribbon tab item to open the **Select File** dialog box.

   File → Read → Data...

2. Read a data file using the **Select File** dialog box.

3. After generating data for a case file, select the **File/Write/Data...** ribbon tab item to open the **Select File** dialog box.

   File → Write → Data...

4. Write a data file using the **Select File** dialog box.

When Ansys Fluent reads a data file, it first looks for a file with the exact name you typed. If a file with that name is not found, it searches for the same file with different extensions, prioritizing CFF files by default. When Ansys Fluent writes a data file, `.dat.h5` is added by default to the name you type.

3.3.3. Reading and Writing Case and Data Files Together

A case file and a data file together contain all the information required to restart a solution. Case files contain the mesh, boundary and cell zone conditions, and solution parameters. Data files contain the values of the flow field in each mesh element and the convergence history (residuals) for that flow field.

You can read a case file and a data file together by using the **Select File** dialog box opened by selecting the **File/Read/Case & Data...** ribbon tab item. To read both files, select the appropriate case file, and the corresponding data file (same name with `.dat.h5` suffix) is also read. Note that the **Display Mesh After Reading** option in the **Select File** dialog box allows you to have the mesh displayed automatically after it is read.

File → Read → Case & Data...

To write a case file and a data file, select the **File/Write/Case & Data...** ribbon tab item.

File → Write → Case & Data...

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3.3.4. Reading and Writing Files in the Legacy Format

When reading and writing case and data files, you can optionally use the legacy format (`.cas` and `.dat`, respectively), which was the default format prior to Release 2020 R1. To read or write legacy case/data files in the current session only, enter the following text command prior to reading or writing:

```
>file/cff-files? no
```

To read or write legacy files in both the current session and future sessions, open the **General** tab of the **Preferences** dialog box, select **Legacy** from the **Default Format for I/O** drop-down list, and click **OK**.

File → **Preferences...**

Ansys Fluent can read and write either text or binary case and data files in the legacy format. Binary files require less storage space and are faster to read and write. By default, Ansys Fluent writes files in binary format. To write a text file, disable the **Write Binary Files** check button in the **Select File** dialog box. In addition, you can read and write either text or binary files in compressed formats (For details, see Reading and Writing Compressed Files (p. 926)). Ansys Fluent automatically detects the file type when reading.

Important:

Computed values for walls, symmetry boundaries, and other surfaces where the results are interpolated from cell centers to the surface, are not retained when you save to the legacy format. This causes issues when legacy case and data files are read into postprocessing applications (such as Ansys EnSight) that do not have an integrated solver, because these applications cannot accurately interpolate the values back to these surfaces. This issue is resolved if you save case and data files in HDF format.

For legacy data files, you can output additional quantities for postprocessing in other applications using the Data File Quantities dialog box (see Setting Data File Quantities (p. 1001)).

For information about the format of legacy case and data files, see Legacy Case and Data File Formats (p. 5617).

3.3.5. Automatic Saving of Case and Data Files

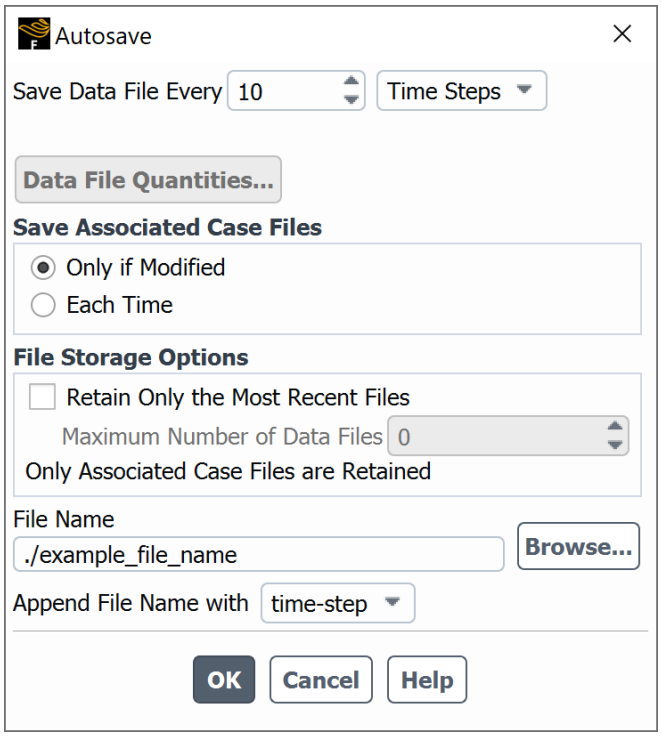
You can request Ansys Fluent to automatically save case and data files at specified intervals during a calculation. This is especially useful for time-dependent calculations, since it allows you to save the results at different time steps, flow times, or crank angles (for in-cylinder simulations) without stopping the calculation and performing the save manually. You can also use the autosave feature for steady-state problems, and thus examine the solution at different stages in the iteration history.

Automatic saving is specified using the Autosave Dialog Box (p. 5136) (Figure 3.2: The Autosave Dialog Box (p. 935)), which is opened by clicking the **Edit...** button next to the **Autosave Every** text box in the **Calculation Activities** task page.

Calculation Activities

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 3.2: The Autosave Dialog Box



Specify how often you would like to save your modified files by entering the frequency in the **Save Data File Every** number-entry field. **Save Data File Every** is set to zero by default, indicating that no automatic saving is performed.

For transient in-cylinder simulations, specify whether you want to save the data by **Time Steps** or **Crank Angles**.

If you choose to save the case file only if it is modified, then select **Only if Modified** under **Save Associated Case Files**. Note that the case file will be saved whether you make a manual change, or if Ansys Fluent makes a change internally during the calculation. If you choose to save the case file every time the data file is saved, then select **Each Time**.

Important:

To save only the data files, use the following TUI option:

`file` → `auto-save` → `case-frequency` → `if-mesh-is-modified`

This will result in the options in the **Save Associated Case Files** group box being disabled in the **Autosave** dialog box. In essence, this TUI command forces Ansys Fluent to the save case file only when the mesh is modified. It does not disable case file saving, but reduces it to an absolute minimum. This is necessary to do so since you cannot read a data file without a case file containing a matching mesh.

For steady-state solutions, specify the frequency in iterations. For transient solutions, specify it in time steps (unless you are using the explicit time stepping formulation, in which case specify the frequency in iterations). For transient in-cylinder solutions, you can choose to specify the frequency in crank

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

angles. If you define a frequency of 5, for example, a case file is saved every 5 iterations, time steps, or crank angles.

If you have limited disk space, restrict the number of files saved by Ansys Fluent by selecting the **Retain Only the Most Recent Files** option. When selected, enter the **Maximum Number of Data Files** you would like to retain. Note that the case and data files are treated separately with regard to the maximum number of files saved when overwriting. For example, if the value of **Maximum Number of Data Files** is set to five, Ansys Fluent saves a maximum of five case and five data files, irrespective of the frequency. After the maximum limit of files has been saved, Ansys Fluent begins overwriting the earliest existing file.

Note:

When the **Retain only the Most Recent Files** option is selected, the solution history currently in memory will be discarded and the solution history reset.

If you have requested the writing of files in the legacy format (see Reading and Writing Files in the Legacy Format (p. 934)), you may need to specify that additional data quantities are written if you want to postprocess in alternative applications. When you have generated data—either by initializing the solution or running the calculation—you can view the list of standard quantities that will be written to the legacy data file as a result of the autosave, and select additional quantities. Click the **Data File Quantities...** button to open the **Data File Quantities** dialog box, and make any necessary selections. For details, see Setting Data File Quantities (p. 1001).

Enter a root name for the autosave files in the **File Name** text box. When the files are saved, a number will be appended to this root name to indicate the point at which it was saved during the calculation: for steady-state solutions, this will be the iteration number, whereas for transient solutions it will be either the time step number, flow time, or crank angle (depending on your selection in the step that follows). An extension will also be automatically added to the root name (`.cas.h5` or `.dat.h5`, by default). If the specified **File Name** ends in `.gz` or `.Z` and you have requested the reading and writing of files in the legacy format, appropriate file compression is performed; for details about file compression, see Reading and Writing Compressed Files (p. 926).

For transient calculations, make a selection from the **Append File Name with** drop-down list to indicate whether you want the root file name to be appended with the **time-step**, **flow-time** or **crank-angle** (see Figure 3.2: The Autosave Dialog Box (p. 935)). If you select either of the latter two, you can set the **Decimal Places in File Name** to determine the ultimate width of the file name.

Consider a transient case for which you want to save your case and data files at known time steps. The procedure you would follow is to first set the frequency in the **Save Data File Every** text box. Select **Each Time** if you want both case and data files saved at the same interval. Then enter `my_file` for the **File Name**. Finally, select **time-step** from the **Append File Name with** drop-down list. An example of the resulting files saved would be

```
my_file-0005.cas.h5
```

```
my_file-0005.dat.h5
```

indicating that these files were saved at the fifth time step.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can revise the instructions for the previous example to instead save case and data files at known flow times, by selecting **flow-time** from the **Append File Name with** drop-down list. The default **Decimal Places in File Name** will be six. An example of the resulting files saved would be

```
my_file-0.500000.cas.h5
```

```
my_file-0.500000.dat.h5
```

indicating that these files were saved at a flow time of 0.5 seconds.

For steady-state and transient cases, you have the option of automatically numbering the files (as described in Automatic Numbering of Files (p. 928)), and thereby include further information about when the files were saved. This involves the addition of special characters to the **File Name**. For example, you may want the file names to convey the flow times with their corresponding time step numbers (transient cases only). Select **time-step** from the **Append File Name with**, and enter a **File Name** that ends with `-%f` to automatically number the files with the flow time. Thus, entering a **File Name** of `filename-%f` could result in a saved case file named `filename-000.500000-0010.cas.h5`. The conventions used in this example can be explained as follows:

- `filename-` is the file name you entered when autosaving your solution.
- `000.500000` is the result of the special character `%f` added to the file name, and is the flow time. This flow time has a field width of ten characters, which allows for six decimal places (as discussed in Automatic Numbering of Files (p. 928)).
- `-0010` is the appended **time-step**, as designated by the selection in the **Append File Name with** drop-down list.
- `.cas.h5` is the file extension automatically added when using the autosave option.

In addition to the case and data files, a single project file (`.flprj`) is also written during the calculation; it is recommended that you read this file whenever possible when postprocessing in CFD-Post and EnSight, as it contains metadata such as the time values for files exported from transient simulations. Note that if the root name of the autosave files is the same as that used for exporting Common Fluids Format - Post files during a transient calculation (using the **Automatic Export** dialog box) and Fluent is set up to save files in the default Common Fluids Format (CFF), then the metadata from both operations will be written to the same project file.

All of the autosave inputs are stored in memory when you click **OK** in the **Autosave** dialog box, and can then be saved with the case file.

Important:

The default path is `./<filename>` indicating that the autosaved files will be saved in the working directory of the current Fluent session. If you hard code a directory, then the files will always be saved at that location, regardless of the working directory of the current Fluent session.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3.4. Reading Settings Only for Mesh or Case Files with Large Cell Counts

When setting up a simulation that has a large cell count, you can read the case settings only of a mesh or case file, without any of the data associated with the mesh. This allows you to review and/or modify the settings without having to wait for the reading of the mesh, on a machine that does not have the memory needed for the mesh (such as a personal computer or laptop). When you read the case settings, note that it is not possible to manipulate the mesh or run calculations, or set up any add-on modules besides the adjoint solver and the population balance model.

To read the case settings for a simulation, perform the following steps:

1. Open up a Fluent session.

   Note:

   - You can enable the **Pre/Post Only** option in Fluent Launcher / use the `-post` command line option.
   - Using a single processor (`-t1`) is recommended, as it will minimize the memory usage. Multiple processors are not necessary for reading the case settings only.

2. Read the case settings for a mesh or case file in the Common Fluids Format (with the `.msh.h5` or `.cas.h5` extension, respectively). This can be done using one of the following methods:

   - Select the **File/Read/Case Settings Only...** ribbon tab item, and use the **Select File** dialog box that opens to select a file.

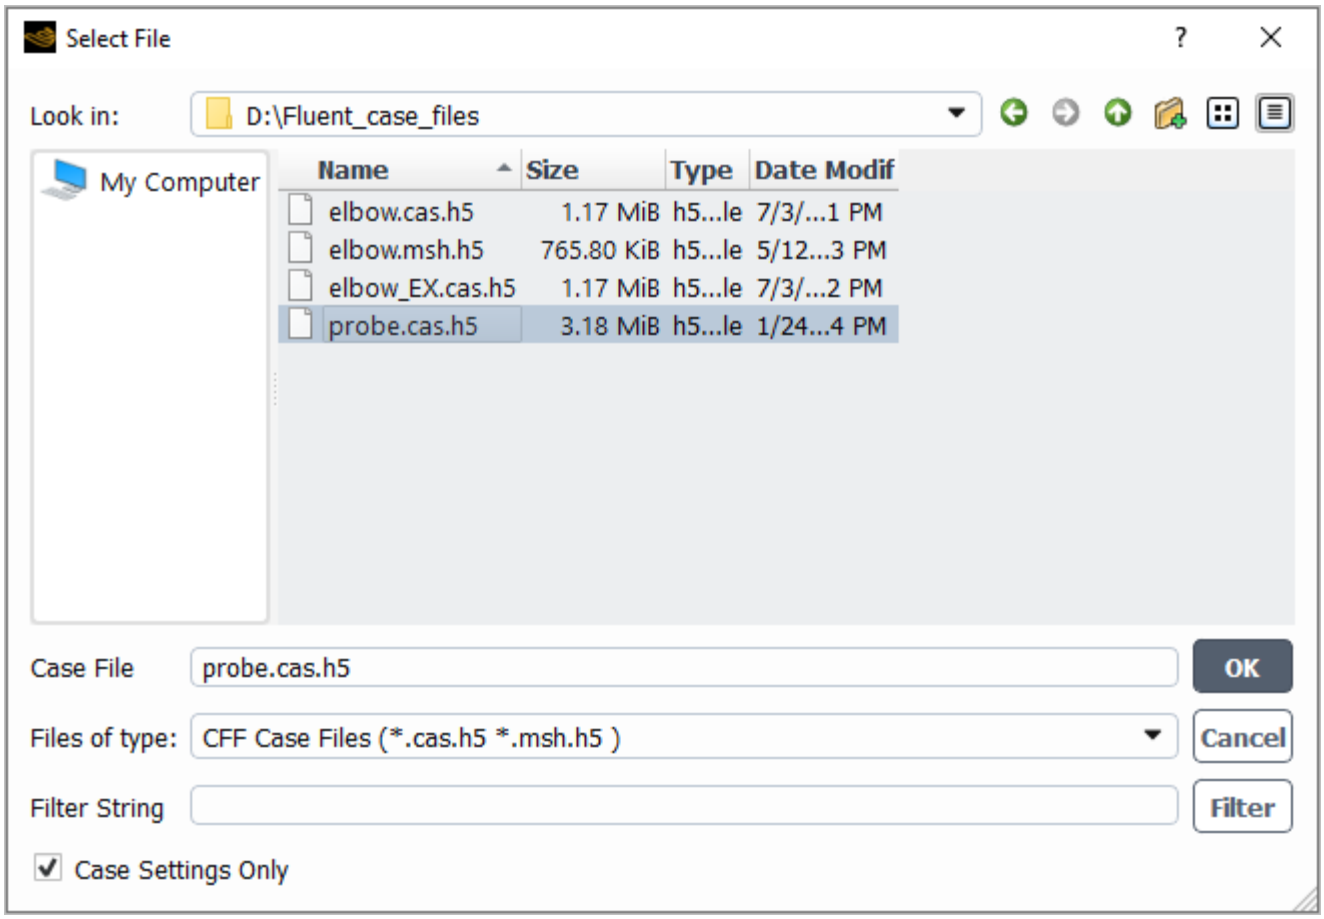
     File → Read → Case Settings Only...

   - Select the **File/Read/Case...** ribbon tab item to open the **Select File** dialog box.

     File → Read → Case...

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 3.3: The Select File Dialog Box for Reading Case Settings Only



Enable the **Case Settings Only** option in the **Select File** dialog box, select a file, and click **OK**.

- Use the following text command:

  `file → read-case-settings`

3. Review and/or modify the settings as necessary. For any operation that is related to the manipulation of the mesh or the running of the calculation, the graphical user interface (GUI) is grayed out, and the text command is unavailable; additionally, the `define/models/addon-module` text command is unavailable. Note that you can initialize the case in order to access settings that are only available after initialization and/or warnings generated during initialization, but data will not be generated.

4. Write the revised settings to a case file. If the name of the case file to which you write is the same as the one you originally read, the writing will be fast and will not require a large amount of memory / file space; if you write using a new case file name, you will have to wait for the copying of the data associated with the mesh from the original case file, and you must have the memory / file space available to allow the copying.

3.5. Reading Fluent/UNS and RAMPANT Case and Data Files

Case files created by Fluent/UNS 3 or 4 or RAMPANT 2, 3, or 4 can be read into Ansys Fluent in the same way that current case files are read (see Reading and Writing Case and Data Files (p. 930)). If you read a case file created by Fluent/UNS, Ansys Fluent selects **Pressure-Based** in the **Solver** group box of the

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

General Task Page (p. 4632). If you read a case file created by RAMPANT, Ansys Fluent selects **Density-Based** in the **Solver** group box of the General Task Page (p. 4632), as well as **Explicit** from the **Formulation** drop-down menu in the Solution Methods Task Page (p. 5103).

Data files created by Fluent/UNS 4 or RAMPANT 4 can be read into Ansys Fluent in the same way that current data files are read (see Reading and Writing Case and Data Files (p. 930)).

3.6. Reading and Writing Profile Files

Boundary profiles are used to specify flow conditions on a boundary zone of the solution domain. For example, they can be used to prescribe a velocity field on an inlet plane. For information on boundary profiles, see Profiles (p. 1540). For information about transient profiles, see Transient Cell Zone and Boundary Conditions (p. 1499).

Profiles can also can also be used in expressions. Refer to Profiles (p. 1023) for additional information.

For additional information, see the following sections:

3.6.1. Reading Profile Files

3.6.2. Writing Profile Files

3.6.1. Reading Profile Files

To read the boundary profile files, open the **Select File** dialog box by selecting the **File/Read/Profile...** ribbon tab item.

File → **Read** → **Profile...**

This opens the **Select File** dialog box so that you can read a boundary profile with the standard extension `.prof` or a transient profile in tabular format with the standard extension `.ttab`. CSV profiles are also supported, see CSV Profiles (p. 1543) for additional information. If a profile in the file has the same name as an existing profile, the old profile will be overwritten.

Note:

The maximum number of profiles that can be read into a single Fluent session is 50.

3.6.2. Writing Profile Files

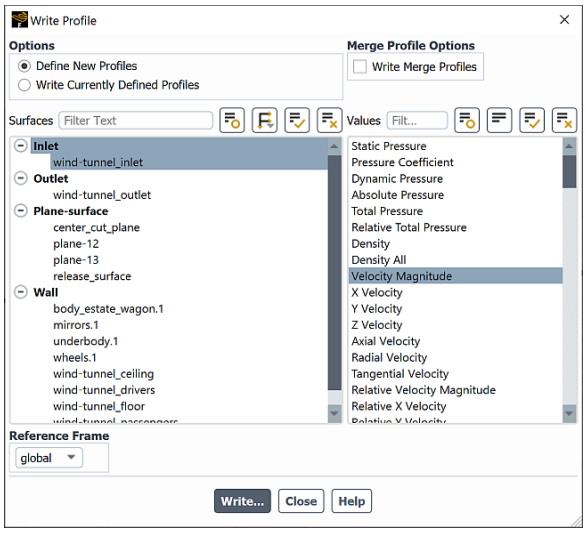
You can also create a profile file from the conditions on a specified boundary or surface. For example, you can create a profile file from the outlet conditions of one case. Then you can read that profile into another case and use the outlet profile data as the inlet conditions for the new case.

To write a profile file, use the Write Profile Dialog Box (p. 4936) (Figure 3.4: The Write Profile Dialog Box (p. 941)).

File → **Write** → **Profile...**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 3.4: The Write Profile Dialog Box



1. Retain the default option of **Define New Profiles**.

2. Select the surface(s) where you want data extracted for the profile(s) in the **Surfaces** list.

3. Choose the variable(s) for which you want to create profiles in the **Values** list.

4. Optionally select **Write Merge Profiles**. This writes a `.csv` file with the selected surfaces consolidated into one set of data points. Note that this option is only available if you have selected 2 or more surfaces.

5. Select the desired **Reference Frame** from the drop-down list that will be used for creating this profile.

6. Click **Write...** and specify the profile file name in the resulting **Select File** dialog box.

   Ansys Fluent saves the mesh coordinates of the data points for the selected surface(s) and the values of the selected variables at those positions. When you read the profile file back into Fluent, you can select the profile values from the relevant drop-down lists in the boundary condition dialog boxes. The names of the profile values in the drop-down lists will consist of the surface name and the particular variable.

7. Select the **Write Currently Defined Profiles** option:

   - if you have made any modifications to the boundary profiles since you read them in (for example, if you reoriented an existing profile to create a new one).

   - if you want to store all the profiles used in a case file in a separate file.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8. Click **Write...** and specify the file name in the resulting **Select File** dialog box. All currently defined profiles are saved in this file. This file can be read back into Fluent whenever you want to use these profiles again.

Note:

- Transformation of point profiles is only available for Cartesian reference frames. *Cylindrical and other reference frame systems are not supported.*
- Scalar point field profiles do not require transformation to a local reference frame.
- Transformation of vector point field profiles (for example, point velocities, acceleration) into local reference frames is not supported.

3.6.2.1. Writing Circumferential-Averaged Profiles

With **Turbo Models** enabled, you have the option to write circumferential-averaged profiles. Circumferential-averaged profiles are available for flow variables on various surfaces including inlet, outlet, interfaces, planes, iso-surfaces, and iso-clips. The determination of the profile type (radial or axial) is internally based on the specific type of machine.

To write a circumferential-average profile, perform the following steps:

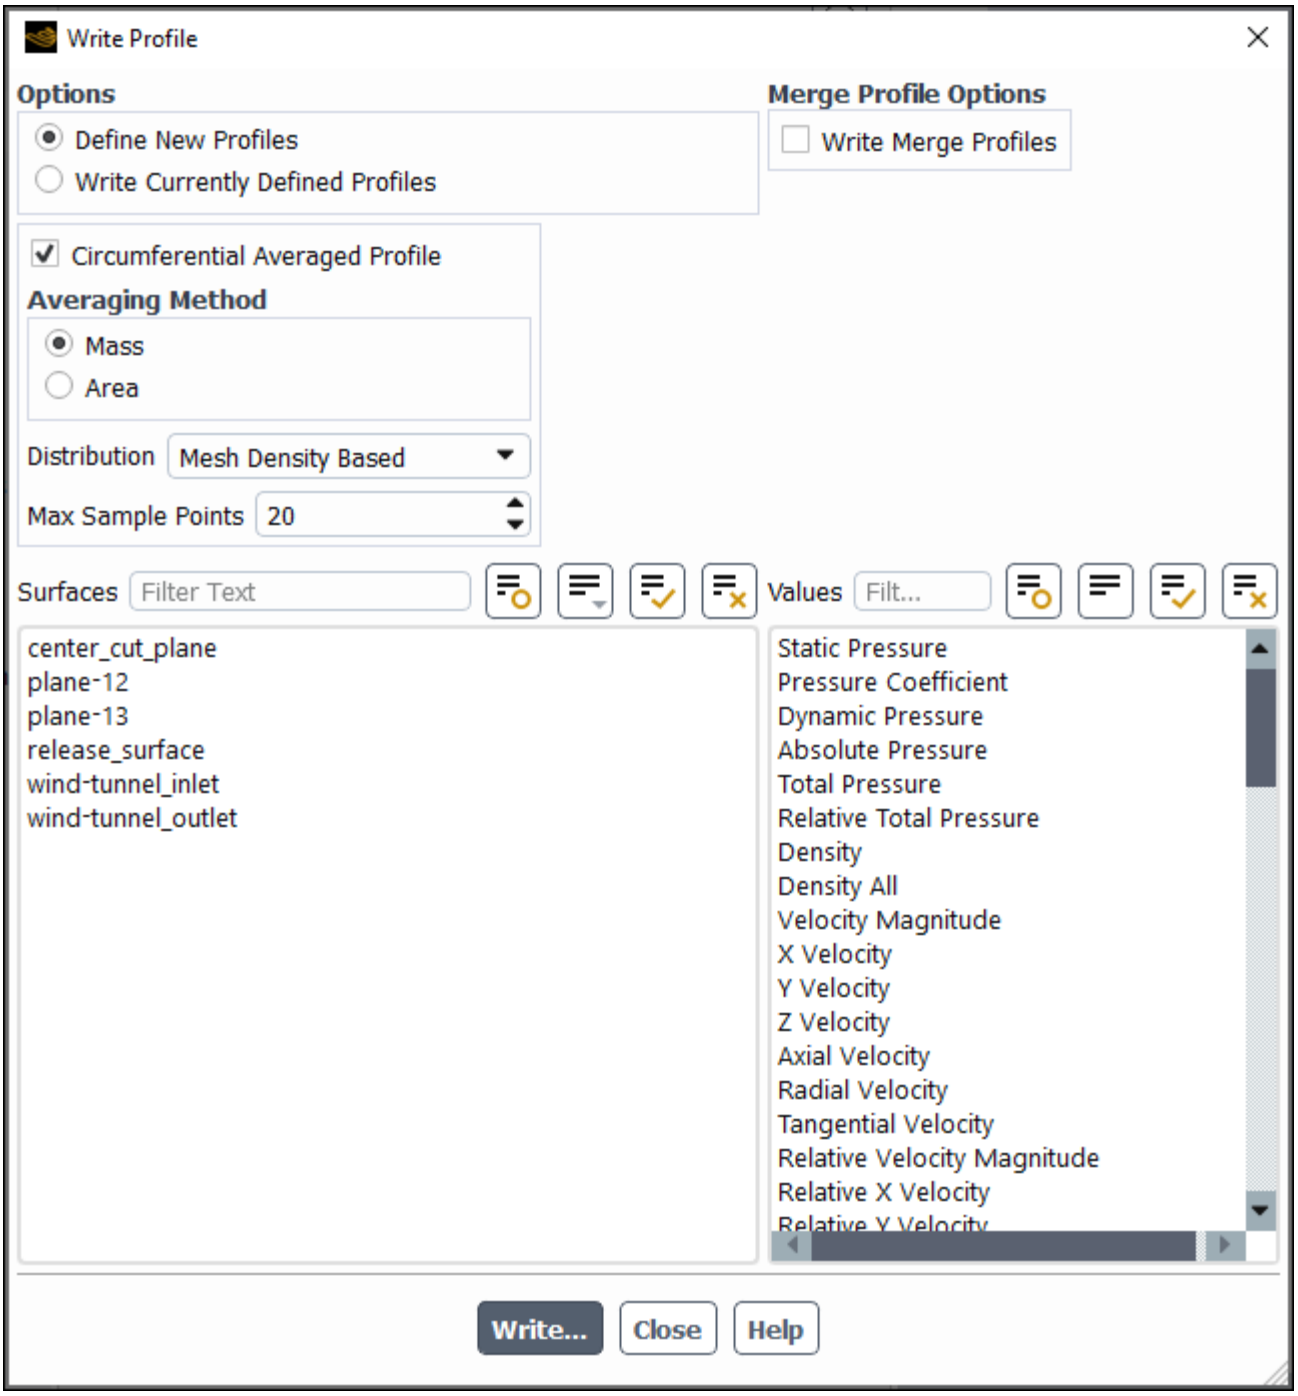
1. Enable **Turbo Models** from the ribbon.

   Domain → **Turbomachinery** → **Turbo Models**

2. On the **Write Profile** dialog box, select **Circumferential Averaged Profile** to reveal additional settings. In most cases, the default settings should be sufficient.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 3.5: The Write Profile Dialog Box



3. Under **Averaging Method**, select **Mass** or **Area**.

4. **Distribution** determines how the averaged values for the profile pitch-wise bands are created. The distribution of bands can either be **Mesh Density Based** or **Equal Distance Based**.

5. **Max Sample Points** specifies the maximum number of bands that are created for sampling.

6. Select the **Surfaces** and **Values** to be included in the profile. If you select `X Velocity`, `Y Velocity`, or `Z Velocity` then Fluent automatically converts them into cylindrical coordinates

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

so that extracted circumferential averaged velocity profile is always written in cylindrical components.

7. Click **Write...** to generate the profile in `.csv` or legacy `.prof` format. Note the main difference between the two formats is the `.csv` format contains additional information in the file header.

You can also access this feature by using the following console command and following the prompts:

```
file/write-circumferential-averaged-profile
```

3.7. Reading Files in Tabular Format

When the tabular input option is available for a solution variable, you can specify the variable as a tabular function of other solution quantities using one or more generic text files. The tabular method uses a bisection algorithm along with local linear interpolation to find the value of the tabulated quantity.

To read the table into Ansys Fluent:

1. Access the **Table File Manager** dialog box in one of the following ways:

   - In the **User-Defined** ribbon tab, click **Read Table** (**User-Defined** group).

     User-Defined → **User-Defined** → **Read Table**

   - In the **File** menu, click **Table File Manager...**.

     File → **Table File Manager...**

2. In the **Table File Manager** dialog box that opens, click **Read...**.

3. Use the **Select File** dialog box to select the file data in tabular format to be read.

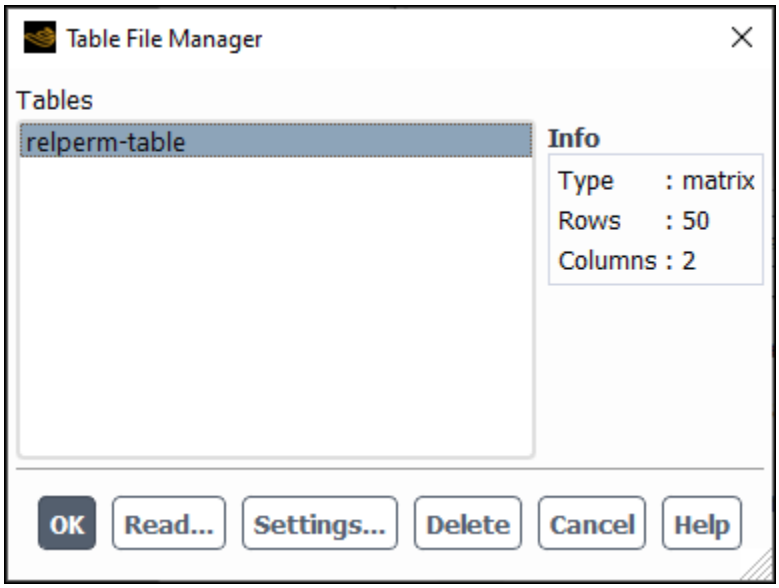
   Note:

   By default, the **Matrix Data Files** is selected as **Files of type**. With this option, all files in your directory will be shown in the **Select File** dialog box. If you want to show only RGP table files, you can select **Real Gas Property (RGP) Table Files (*.rgp)** for **Files of type**.

Once Ansys Fluent loads the file, the table name appears in the **Tables** selection list in the **Table File Manager** dialog box (see Figure 3.6: The Table File Manager Dialog Box (p. 945)). The table attributes, such as the table type and number of rows and columns, are displayed in the **Info** field.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 3.6: The Table File Manager Dialog Box



You can add or delete tables at any time by using the **Read...** or **Delete...** buttons.

3.7.1. Matrix Table Files

The text file can be any tab- (or space-) delimited file and must contain the entries described below. See Capillary Pressure Data in a Tabular Format (p. 1344) for example of a file in tabular format for tabular definition of capillary pressure.

Row 1 – The name of the table. The name should not exceed 128 characters and contain no spaces.

Row 2 – Column names for the table input data.

Row 3 and all consecutive rows – Data points. Note that although there are no limits on the number of rows and columns, the files are intended to be relatively small (a few hundred data points maximum), since they will be stored as part of the case file.

Each row in the table must be terminated by a newline or carriage return with no space or tab following the last entry in the row.

You must provide an adequate number of data points in order to obtain meaningful results for interpolated variables. The values of the interpolated quantity appearing in the first and last rows of the table are used as its lower and upper bounds, respectively.

Unlike locally stored files, these tables, once read in, are written out as part of the Fluent case file. You do not have to maintain local copies of the tables.

3.7.2. Real Gas Property (RGP) Table Files

Real Gas Property (RGP) tables provide thermodynamic and transport material properties as functions of temperature and pressure. Each table may contain data for supercritical state, vapor/liquid subcritical states, and saturation properties.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The detailed description of the contents and format of RGP files can be found in Real Gas Property (RGP) File Contents and Real Gas Property (RGP) File Format in the *CFX-Solver Modeling Guide*. See Using Real Gas Property (RGP) Table Files (p. 1705) for details on using RGP files.

3.8. Reading and Writing Boundary Conditions

To save all currently defined boundary conditions to a file, enter the `file/write-settings` text command and specify a name for the file.

`file` → `write-settings`

Ansys Fluent writes the boundary and cell zone conditions, the solver, and model settings to a file using the same format as the "zone" section of the case file.

To read boundary conditions from a file and to apply them to the corresponding zones in your model, enter the `file/read-settings` text command.

`file` → `read-settings`

Ansys Fluent sets the boundary and cell zone conditions in the current model by comparing the zone name associated with each set of conditions in the file with the zone names in the model. If the model does not contain a matching zone name for a set of boundary conditions, those conditions are ignored.

If you read boundary conditions into a model that contains a different mesh topology (for example, a cell zone has been removed), check the conditions at boundaries within and adjacent to the region of the topological change. This is important for wall zones.

Note:

If the boundary conditions are not checked and some remain uninitialized, the case will not run successfully.

When the `file/read-settings` text command is not used, all boundary conditions get the default settings when a mesh file is imported, allowing the case to run with the default values.

If you want Ansys Fluent to apply a set of conditions to multiple zones with similar names, or to a single zone with a name you are not sure of in advance, you can edit the boundary-condition file saved with the `file/write-settings` command to include *wildcards* (`*`) within the zone names. For example, if you want to apply a particular set of conditions to **wall-12**, **wall-15**, and **wall-17** in your current model, edit the boundary-condition file so that the zone name associated with the desired conditions is `wall-*`.

Note:

The settings file contains only your user-modified settings and does not include default Ansys Fluent parameters. The default parameters may be updated with each new release. Consequently, the usage of the same settings file in different releases of Ansys Fluent does not guarantee the same setup, which can cause solution differences.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3.9. Writing a Boundary Mesh

You can write the boundary zones (surface mesh) to a file. This file can be read and used by the meshing mode of Fluent to produce a volume mesh. You may find this feature useful if you are unsatisfied with a mesh obtained from another mesh generation program.

A boundary mesh can be written using the **Select File** dialog box, opened by selecting the **File/Write/Boundary Mesh...** ribbon tab item.

File → Write → Boundary Mesh...

3.10. Reading Scheme Source Files

A Scheme source file can be loaded in three ways: through the menu system as a scheme file, through the menu system as a journal file, or through Scheme itself.

For large source files, use the **Select File** dialog box, opened by selecting the **File/Read/Scheme...** ribbon tab item

File → Read → Scheme...

or use the Scheme `load` function in the console, as shown in the following example:

```
> (load "file.scm")
```

Shorter files can also be loaded with the **File/Read/Journal...** ribbon tab item or the `file/ read-journal` command in the text interface (or its `.` or `source` alias, as shown in the example that follows).

```
>. file.scm

> source file.scm
```

In this case, each character of the file is echoed to the console as it is read, in the same way as if you were typing in the contents of the file.

3.11. Creating and Reading Journal Files

A journal file contains a sequence of Ansys Fluent commands, arranged as they would be typed interactively into the program or entered through the GUI or TUI. The GUI and TUI commands are recorded as Scheme code lines in journal files. You can also create journal files manually with a text editor. If you want to include comments in your file, be sure to put a semicolon (`;`) at the beginning of each comment line. For an example, see Background Execution on Linux Systems (p. 202) in the Getting Started (p. 1) part of this manual.

The purpose of a journal file is to automate a series of commands instead of entering them repeatedly on the command line. Another use is to produce a record of the input to a program session for later reference, although transcript files are often more useful for this purpose. (For details, see Creating Transcript Files (p. 951)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Command input is taken from the specified journal file until its end is reached, at which time control is returned to the standard input (usually the keyboard). Each line from the journal file is echoed to the standard output (usually the screen) as it is read and processed.

Important:

- A journal file is, by design, just a simple record and playback facility. It contains no information about the state in which it was recorded (other than the version of Ansys Fluent that it was created in) or the state in which it is being played back.
- The precision (single or double) that the journal is recorded in may affect playback when it is read into a session that is running in the other precision.

- Be careful not to change the folder while recording a journal file. Also, try to re-create the state in which the journal was written before you read it into the program. For example, if your journal file includes an instruction to save a new file with a specified name, you should check that if a file with that name exists in your folder before you read in your journal file. If a file with that name exists and you read in your journal file, when the program reaches the write instruction, it will prompt for a confirmation to overwrite the old file.

  Since the journal file does not contain any response to the confirmation request, Ansys Fluent cannot continue to follow the instructions of the journal file.

- Other conditions that may affect the program's ability to perform the instructions contained in a journal file can be created by modifications or manipulations that you make within the program.

  For example, if your journal file creates several surfaces and displays data on those surfaces, you must be sure to read in appropriate case and data files before reading the journal file.

  Important:

  At a point of time, only one journal file can be open for recording, but you can write a journal and a transcript file simultaneously. You can also read a journal file at any time.

- Whenever you start recording a journal file, the text command `/file/set-tui-version "XX.X"` is added at the top of the file (where `XX.X` corresponds to the version of Ansys Fluent that is recording the journal file). This text command can help journals created in an older version to work properly when used in a newer version, as it will hide the new text user interface (TUI) prompts and restore the deleted TUI prompts in that newer version.

  If you are writing a journal file in a text editor, it is recommended that you add `/file/set-tui-version "XX.X"` at the top of the file.

  Note:

  – The specified version must be within two full releases of the version that is running the journal.

  – To specify version 2024 R1, enter `"24.1"` for `"XX.X"`.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Whether you choose to type the text command in full or use partial strings (as described in Command Abbreviation), complete commands are recorded in the journal files. Consider the following examples:

- Typing in the TUI

  ```
  mesh/smooth-mesh , 5 ,
  ```

  will be recorded in the journal file as

  ```
  /mesh/smooth-mesh "quality based" 5 0.1
  ```

  where , or **Enter** signifies default values or entries, as described in Text Prompt System.

- Typing in the TUI

  ```
  so set ur mom 0.2 pres 0.4
  ```

  will be recorded in the journal file as two separate commands:

  ```
  /solve/set/under-relaxation/mom 0.2
  /solve/set/under-relaxation/pressure 0.4
  ```

Important:

- Only successfully completed commands are recorded. For example, if you stopped an execution of a command using **Ctrl**+**c**, it will not be recorded in the journal file.
- If a GUI event happens while a text command is in progress, the GUI event is recorded first.
- All default values are recorded (as in the first example above).

For additional information, see the following section:

3.11.1. Procedure

3.11.2. Multiple Journal Files

3.11.1. Procedure

To start the journaling process, select the **File/Write/Start Journal...** ribbon tab item.

File → Write → Start Journal...

After you enter a name for the file in the **Select File** dialog box, journal recording begins. The **Start Journal...** menu item becomes the **Stop Journal** menu item. You can end journal recording by selecting **Stop Journal**, or by exiting the program.

File → Write → Stop Journal

You can read a journal file into the program using the **Select File** dialog box opened by selecting the **File/Read/Journal...** ribbon tab item.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

File → Read → Journal...

Journal files are always loaded in the main (that is, top-level) text menu, regardless of where you are in the text menu hierarchy when you invoke the read command.

3.11.2. Multiple Journal Files

It is possible to read multiple journal files into Fluent at once.

To read multiple journal files through the **Select File** dialog box:

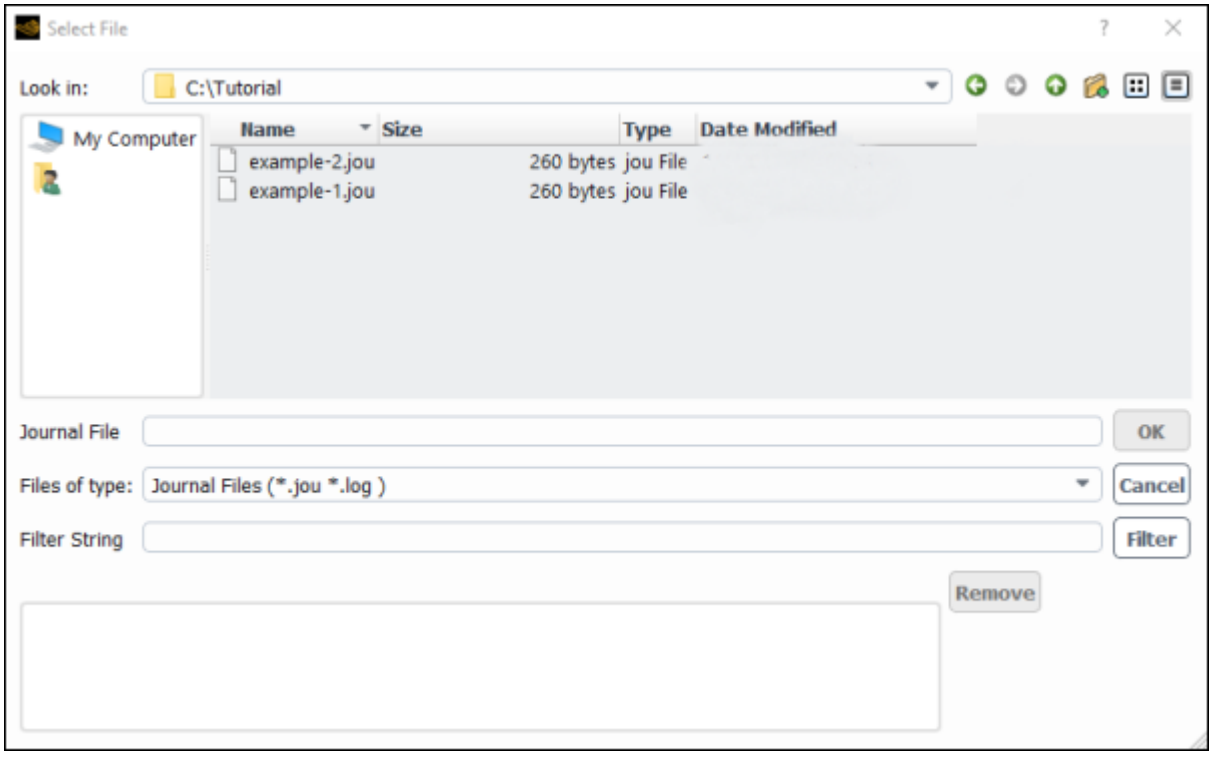
1. Open the **Select File** dialog box.

   File → Read → Journal...

2. Select your files in the order you want them read into Fluent.

   The order in which they will be read is indicated by the red box in Figure 3.7: Multiple Selection of Journal Files (p. 950).

   Figure 3.7: Multiple Selection of Journal Files



3. Click **OK** to load the selected files.

Nested Journal Files

It is possible to create a journal file that makes calls to other journal files.

The following is an example of a nested journal file:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
/file/read-journal "E:/Example_journals_example1.jou" ""
/file/read-journal "E:/Example_journals_example2.jou" ""
/file/read-journal "E:/Example_journals_example3.jou" ""
```

3.12. Creating Transcript Files

A transcript file contains a complete record of all standard input to and output from Ansys Fluent (usually all keyboard and GUI input and all screen output) including the start, end, and total time of the session, as well as the wall-clock time taken per iteration. GUI commands are recorded as Scheme code lines in transcript files. Ansys Fluent creates a transcript file by recording everything typed as input or entered through the GUI, and everything printed as output in the text window.

The purpose of a transcript file is to produce a record of the program session for later reference. Because they contain messages and other output, transcript files (unlike journal files), cannot be read back into the program.

You can set the **Automatic Transcript** option in the **General** branch of Preferences to automatically record a transcript file starting at the beginning of each new Ansys Fluent session. Automatically created transcripts are named as follows: `fluent-YYYYMMDD-HHMMSS-<processID>.trn`, where `YMD` stand for "year" "month" "day" and `HMS` stand for "hour" "minute" "second".

File → Preferences... → General → Automatic Transcript

The transcript is saved to the working directory if it is writable, otherwise it is saved in the temporary directory. *The absolute path of the temporary directory varies for Windows and Linux, but in all cases, the path where the transcript file is saved is printed in the Console.*

Important:

Only one transcript file can be open for recording at a time (except if you have **Automatic Transcript** enabled, then you can still create an additional transcript file), but you can write a transcript and a journal file simultaneously. You can also read a journal file while a transcript recording is in progress.

To start the transcription process, select the **File/Write/Start Transcript...** ribbon tab item.

File → Write → Start Transcript...

After you enter a name for the file in the **Select File** dialog box, transcript recording begins and the **Start Transcript...** menu item becomes the **Stop Transcript** menu item.

You can end transcript recording by selecting **Stop Transcript**, or by exiting the program.

File → Write → Stop Transcript

3.13. Importing Files

Ansys Fluent allows you to import the following file formats:

- ABAQUS `.inp`, `.fil`, and `.odb` files*

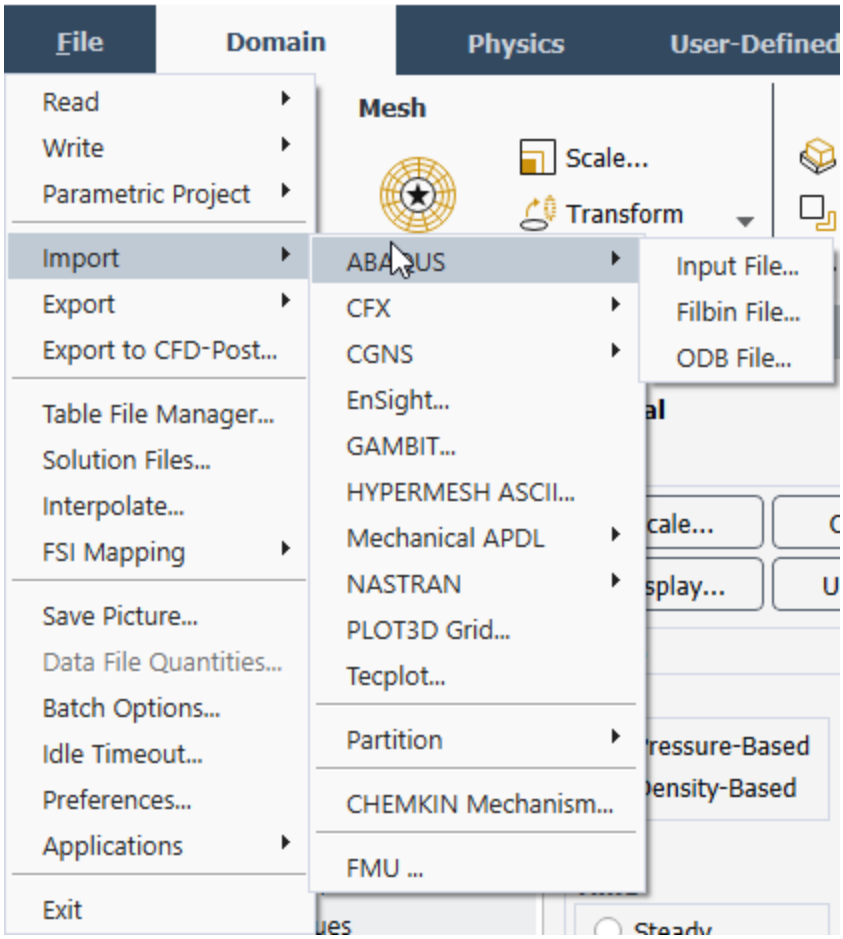
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- CFX `.def` and `.res` files
- CGNS files*
- EnSight files*
- GAMBIT files
- HYPERMESH ASCII files*
- Mechanical APDL `.inp`, `.cdb`, `.rst`, and `.rmg` files*
- NASTRAN Bulk Data files*
- PLOT3D mesh files*
- Tecplot files*

*Requires a VKI license

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 3.8: The Import Menu



Important:

Once you have imported any 3rd party file it is recommended that you confirm that the boundary zones and cell zones are set up as you expect.

For information on importing particle history data, see Importing Particle Data (p. 2841).

For additional information, see the following sections:

3.13.1. ABAQUS Files
3.13.2. CFX Files
3.13.3. Meshes and Data in CGNS Format
3.13.4. EnSight Files
3.13.5. GAMBIT and GeoMesh Mesh Files
3.13.6. HYPERMESH ASCII Files
3.13.7. Mechanical APDL Files
3.13.8. NASTRAN Files
3.13.9. PLOT3D Files
3.13.10. Tecplot Files

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3.13.11. Partition Files
3.13.12. CHEMKIN Mechanism

3.13.1. ABAQUS Files

To import an ABAQUS input file, use the **File/Import/ABAQUS/Input File...** ribbon tab item.

File → Import → ABAQUS → Input File...

Select this menu item to open the **Select File** dialog box. Specify the name of the ABAQUS **Input File** to be read. The ABAQUS input file (.inp) is a text file that contains the input description of a finite element model for the ABAQUS finite element program. The interface only produces datasets associated with the finite element model, no results of datasets are produced. Element types commonly associated with structural analysis are supported by this file format. There is a list of input keywords that are recognized in the ABAQUS **Input File** [4] (p. 5655).

To import an ABAQUS filbin file, use the **File/Import/ABAQUS/Filbin File...** ribbon tab item.

File → Import → ABAQUS → Filbin File...

Select this menu item to open the **Select File** dialog box. Specify the name of the ABAQUS **Filbin File** to be read. This output file has a `.fil` extension and consists of finite element model and results data.

To import an ABAQUS ODB file, use the **File/Import/ABAQUS/ODB File...** ribbon tab item.

File → Import → ABAQUS → ODB File...

Select this menu item to open the **Select File** dialog box. Specify the name of the ABAQUS **ODB File** to be read. This output database file has a `.odb` extension and consists of finite element model and results data in the OpenDocument format.

3.13.2. CFX Files

To import a CFX definition file, use the **File/Import/CFX/Definition File...** ribbon tab item.

File → Import → CFX → Definition File...

Select this menu item to open the **Select File** dialog box. Specify the name of the CFX **Definition File** to be read. Fluent reads mesh information from the CFX file with `.def` extensions. For information about importing CFX files, see CFX Files (p. 1131).

To import a CFX result file, use the **File/Import/CFX/Result File...** ribbon tab item.

File → Import → CFX → Result File...

In the **Select File** dialog box, specify the name of the CFX **Result File** to be read. Those imported files will have `.res` extensions.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note that the **Create Zones from CCL Physics Data** option in the **Select File** dialog boxes allows you to create zones from the physics data objects or the primitive mesh region objects.

Important:

CFX file import is available for 3D cases only.

3.13.3. Meshes and Data in CGNS Format

To import meshes in CFD general notation system (CGNS) format (`.cgns`) into Ansys Fluent, use the **File/Import/CGNS/Mesh...** ribbon tab item.

File → Import → CGNS → Mesh...

To import a mesh and the corresponding CGNS data, use the **File/Import/CGNS/Mesh & Data...** ribbon tab item.

File → Import → CGNS → Mesh & Data...

To import only the CGNS data, use the **File/Import/CGNS/Data...** ribbon tab item.

File → Import → CGNS → Data...

Table 3.1: CGNS Variables Supported by Ansys Fluent

CGNS Variable Name	Ansys Fluent Name
Pressure	pressure
ReynoldsStressXX	uu-stress
ReynoldsStressXY	uv-stress
ReynoldsStressXZ	uw-stress
ReynoldsStressYY	vv-stress
ReynoldsStressYZ	vw-stress
ReynoldsStressZZ	ww-stress
Temperature	temperature
TurbulentDissipation	epsilon
TurbulentDissipationRate	omega
TurbulentEnergyKinetic	k
VelocityX	x-velocity
VelocityY	y-velocity
VelocityZ	z-velocity

Important:

- To import data correctly, first import the mesh using the mesh only option (**Mesh...**) and set up the boundary conditions. For example, if a boundary zone is of type **pressure-**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

outlet and is read as **outlet**, it should be changed to **pressure-outlet** before importing the data. Then select the appropriate model and read the data using the data only option (**Data...**)

- The new and original meshes should have the same zones, numbered in the same order. A warning is issued if they do not, because inconsistencies can create problems with the boundary conditions.
- Ansys Fluent defaults to the **Laminar Viscous Model** after reading a CGNS mesh. You must select the appropriate model before reading data since Ansys Fluent selectively imports only those values from the CGNS file required for a given model. For example, if **Epsilon** is available in the CGNS file, the model must be changed to **k-epsilon** to ensure that Ansys Fluent will import this quantity.
- (Linux only) Ensure that the `LC_NUMERIC` and `LC_ALL` are either not set or set to `en_US` prior to launching Ansys Fluent.

3.13.4. EnSight Files

You can import an EnSight file using the **File/Import/EnSight...** ribbon tab item.

File → Import → EnSight...

This file format is applied to both unstructured and structured data, where each part contains its own local coordinate array. The EnSight Gold software package, which uses this file format, allows you to analyze, visualize, and communicate engineering datasets. It allows you to take full advantage of parallel processing and rendering and supports a range of virtual reality devices. Furthermore, it enables real-time collaboration.

When selecting this option, the **Select File** dialog box will appear, where you will specify a file name. This file will have an `.encas` or `.case` extension.

Only the mesh file is read into Ansys Fluent, and any data present is discarded.

3.13.5. GAMBIT and GeoMesh Mesh Files

If you have saved a neutral file from GAMBIT, rather than an Ansys Fluent mesh file, you can import it into Ansys Fluent using the **File/Import/GAMBIT...** ribbon tab item.

File → Import → GAMBIT...

For information about importing files from GAMBIT and GeoMesh, see GAMBIT Mesh Files (p. 1126) and GeoMesh Mesh Files (p. 1126).

3.13.6. HYPERMESH ASCII Files

You can read a HYPERMESH ASCII file using the **File/Import/HYPERMESH ASCII...** ribbon tab item.

File → Import → HYPERMESH ASCII...

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

HYPERMESH is a high-performance finite element pre- and postprocessor for popular finite element solvers, allowing engineers to analyze product design performance in a highly interactive and visual environment.

When selecting this option, the **Select File** dialog box will appear, where you will specify a file name. This file should have an `.hm`, `.hma`, or `.hmascii` extension.

3.13.7. Mechanical APDL Files

To import a Mechanical APDL input file, use the **File/Import/Mechanical APDL/Input File...** ribbon tab item.

File → Import → Mechanical APDL → Input File...

Select this menu item to open the **Select File** dialog box. Specify the name of the Mechanical APDL **Prep7 File** to be read. Fluent reads mesh information from the Mechanical APDL file with `.ans`, `.neu`, `.cdb`, and `.prep7` extensions. For information about importing Mechanical APDL files, see Mechanical APDL Files (p. 1130).

To import a Mechanical APDL result file, use the **File/Import/Mechanical APDL/Result File...** ribbon tab item.

File → Import → Mechanical APDL → Result File...

In the **Select File** dialog box. Specify the name of the Mechanical APDL **Result File** to be read. Those imported files will have `.rst`, `.rth`, and `.rmg` extensions.

3.13.8. NASTRAN Files

You can read NASTRAN Bulkdata files into Ansys Fluent with the **File/Import/NASTRAN/Bulkdata File...** ribbon tab item.

File → Import → NASTRAN → Bulkdata File...

When you select the **Bulkdata File...** menu item, the **Select File** dialog box will appear and you will specify the name of the NASTRAN **File** to be read. This file will have `.nas*`, `.dat*`, `.bdf*` file extensions. Fluent reads mesh information from the NASTRAN file. For information about importing NASTRAN files, see NASTRAN Files (p. 1128).

To import NASTRAN Op2 files into Ansys Fluent, use the **File/Import/NASTRAN/Op2 File...** ribbon tab item.

File → Import → NASTRAN → Op2 File...

In the **Select File** dialog box, specify the name of the NASTRAN **Output2 File** to be read. This file is an output binary data file that contains data used in the NASTRAN finite element program. This file will have `.op2` file extension.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3.13.9. PLOT3D Files

To import a PLOT3D mesh file, use the **File/Import/PLOT3D Grid...** ribbon tab item.

File → **Import** → **PLOT3D Grid...**

The PLOT3D mesh files have `.p3d`, `.bin`, `.x`, `.xyz`, or `.grd` file extensions.

These file formats may be formatted, unformatted or binary.

3.13.10. Tecplot Files

To import a Tecplot file, use the **File/Import/Tecplot...** ribbon tab item.

File → **Import** → **Tecplot...**

This will open the **Select File** dialog box. Specify the name of the neutral file to be read.

The Tecplot file is a binary file. Only the mesh is read into Ansys Fluent and any data present is discarded.

The form of the file must have the `.plt` extension. Ansys Fluent supports the importation of polyhedral cells and files created by Tecplot version 7.1–11.2, except for version 11.0 (which is unsupported).

3.13.11. Partition Files

To perform METIS partitioning on an unpartitioned mesh, use the **File/Import/Partition/Metis...** ribbon tab item.

File → **Import** → **Partition** → **Metis...**

You may also partition each cell zone individually, using the **File/Import/Partition/Metis Zone...** ribbon tab item.

File → **Import** → **Partition** → **Metis Zone...**

See Using the Partition Filter (p. 4304) for detailed information about partitioning.

3.13.12. CHEMKIN Mechanism

To import a CHEMKIN format, you can import the mechanism file into Ansys Fluent using the **File/Import/CHEMKIN Mechanism...** ribbon tab item (Figure 18.5: The Import CHEMKIN Format Mechanism Dialog Box for Volumetric Kinetics (p. 2368)).

File → **Import** → **CHEMKIN Mechanism...**

See Importing a Volumetric Kinetic Mechanism in CHEMKIN Format (p. 2366) for detailed information on importing a CHEMKIN Mechanism file.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3.14. Exporting Solution Data

The current release of Ansys Fluent allows you to export data to ABAQUS, Mechanical APDL Input, ASCII, **AVS**, CDAT for CFD-Post and EnSight, CGNS, Common Fluids Format - Post, EnSight Case Gold, EnSight DVS, **Data Explorer**, FAST, FIELDVIEW, **I-deas**, NASTRAN, **PATRAN**, TAITherm, and Tecplot formats. Exporting Solution Data after a Calculation (p. 961) explains how to export solution data in these formats after the calculation is complete, and ABAQUS Files (p. 962) to Tecplot Files (p. 974) provide specific information for each type of **File Type**. For information about exporting solution data during transient flow solutions, see Exporting Data During a Transient Calculation (p. 976).

Fluent exports to third party software formats in the versions listed in Table 1.2: Supported Versions of Third-Party Software (p. 167).

For NASTRAN, ABAQUS, Mechanical APDL Input, I-deas Universal, and PATRAN file formats, the following quantities are exported [4] (p. 5655):

- Nodes, Elements
- Node Sets (Boundary Conditions)
- Temperature
- Pressure
- Heat Flux
- Heat Transfer Coefficient
- Force

  To generate the force data that is exported for nodes at boundaries, Ansys Fluent performs the following steps:

  1. Facial force for each wall face is calculated by summing the pressure force, viscous force and surface tension force of the face.
  2. Partial force for each wall face is calculated by dividing its facial force by its number of shared nodes.
  3. Total force for each wall node is calculated by summing the partial forces of all the wall faces sharing that node.

For additional information, see the following section:

3.14.1. Exporting Limitations

3.14.1. Exporting Limitations

Note the following limitations when exporting solution data:

- When using the parallel version of Ansys Fluent, you can only export to the following packages:
  - ABAQUS

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

  - CDAT for CFD-Post and EnSight
  - ASCII
  - CGNS
  - Common Fluids Format - Post
  - EnSight Case Gold
  - EnSight DVS
  - Fieldview Unstructured
  - Mechanical APDL Input
  - NASTRAN
  - TAITherm

    Note that parallel TAITherm export is only available for surface data.
  - Tecplot

  The exported file will be written by the host process (see Introduction to Parallel Processing (p. 4259)). Note that the memory required to write the file may exceed the memory available to the host process.

- When using the serial version of Ansys Fluent, you can only export surface data for TAITherm software.
- The solution mode of Fluent cannot import surfaces. Consequently, if you export a file from Ansys Fluent with surfaces selected, you may not be able to read these files back into the solution mode. However, the meshing mode of Fluent can import surface data (see the Fluent Meshing section of the User's Guide for details).
- The following file types require a VKI license: ABAQUS, CGNS, **Ideas-Universal**, NASTRAN, **PATRAN**, Tecplot.
- Ansys Fluent supports exporting polyhedral data only for ASCII, CDAT for CFD-Post and EnSight, CGNS, Common Fluids Format - Post, EnSight Case Gold, EnSight DVS, Fieldview Unstructured, NASTRAN, TAITherm, and Tecplot file formats. For further details, see ASCII Files (p. 963), CDAT for CFD-Post and EnSight (p. 963), CGNS Files (p. 964), Common Fluids Format - Post Files (p. 966), EnSight Case Gold Files (p. 967), FieldView Unstructured Files (p. 971), NASTRAN Files (p. 973), TAITherm Files (p. 973), and Tecplot Files (p. 974).
- If the files that are exported during multiple transient simulations are to be used as a set, you must make sure that all of the simulations are run on the same platform, using the same number of processors. This ensures that all of the files are compatible with each other.
- Data on user defined/created surfaces is not available for export to EnSight Case Gold file format.
- (Windows only) You cannot export files larger than 2GB to CGNS format. As a workaround, use a Linux machine to export files larger than 2GB to CGNS format.

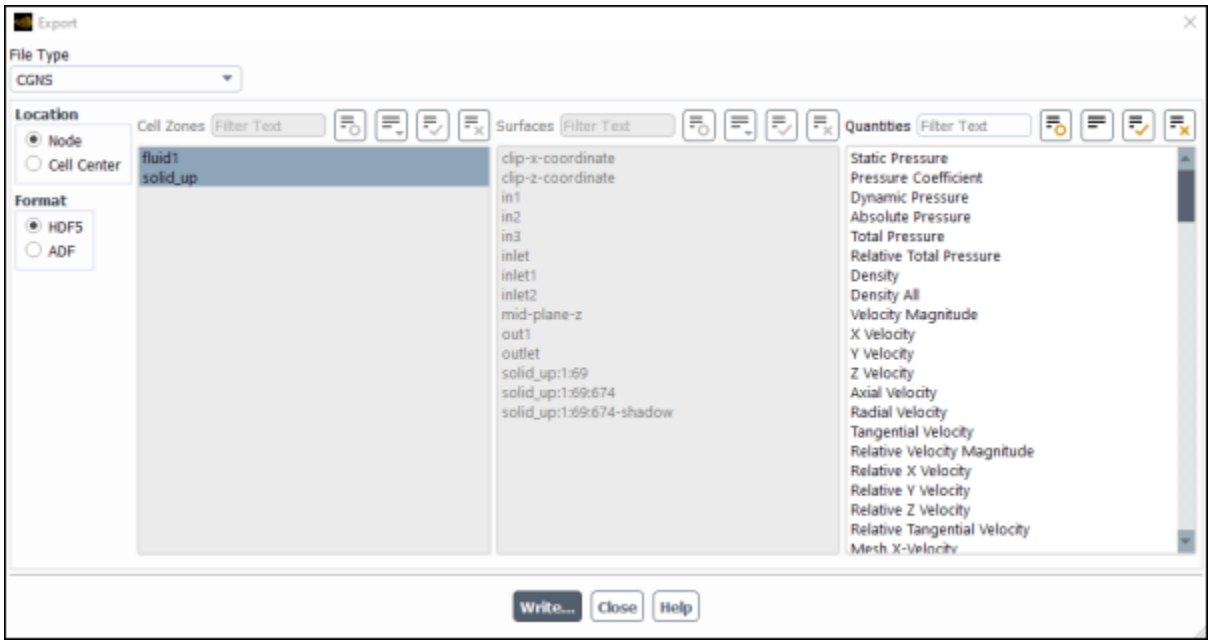
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3.15. Exporting Solution Data after a Calculation

To export solution data to a different file format after a calculation is complete, use the Export Dialog Box (p. 5308) (Figure 3.9: The Export Dialog Box (p. 961)).

File → Export → Solution Data...

Figure 3.9: The Export Dialog Box



Information concerning the necessary steps and available options for each **File Type** are listed in ABAQUS Files (p. 962) to Tecplot Files (p. 974).

For details about general limitations for exporting solution data and the manner in which it is exported, see Exporting Solution Data (p. 959).

For additional information, see the following sections:

- 3.15.1. ABAQUS Files
- 3.15.2. Mechanical APDL Input Files
- 3.15.3. ASCII Files
- 3.15.4. CDAT for CFD-Post and EnSight
- 3.15.5. CGNS Files
- 3.15.6. Common Fluids Format - Post Files
- 3.15.7. EnSight Case Gold Files
- 3.15.8. EnSight DVS
- 3.15.9. FAST Files
- 3.15.10. FAST Solution Files
- 3.15.11. FieldView Unstructured Files
- 3.15.12. NASTRAN Files

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3.15.13. TAITherm Files
3.15.14. Tecplot Files

3.15.1. ABAQUS Files

Select ABAQUS from the **File Type** drop-down list and choose the surface(s) for which you want to write data in the **Surfaces** list. If no surfaces are selected, the entire domain is exported.

When the **Energy Equation** is enabled in the Energy Dialog Box (p. 4662), you can choose the loads to be written based on the kind of finite element analysis you intend to undertake. By selecting **Structural** in the **Analysis** list, you can select the following **Structural Loads**: **Force**, **Pressure**, and **Temperature**. By selecting **Thermal** in the **Analysis** list, you can select the following **Thermal Loads**: **Temperature**, **Heat Flux**, and **Heat Trans Coeff**. Note the following limitations with these loads:

- When the **Energy Equation** is disabled, only the **Structural Loads** options of **Force** and **Pressure** are available.
- Loads are written only on boundary walls when the entire domain is exported (that is, if no **Surfaces** are selected).

Click the **Write...** button to save the file, using the **Select File** dialog box. The exported file format of ABAQUS (`file.inp`) contains coordinates, connectivity, zone groups, and optional loads.

Export of data to ABAQUS is valid only for solid zones or for those surfaces that lie at the intersection of solid zones. Temperature data is exported for the whole domain.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See Exporting Data During a Transient Calculation (p. 976) for the complete details.

3.15.2. Mechanical APDL Input Files

Select Mechanical APDL Input from the **File Type** drop-down list and choose the surface(s) for which you want to write data in the **Surfaces** list. If no surfaces are selected, the entire domain is exported.

When the **Energy Equation** is enabled in the Energy Dialog Box (p. 4662), you can choose the loads to be written based on the kind of finite element analysis you intend to undertake. By selecting **Structural** in the **Analysis** list, you can select the following **Structural Loads**: **Force**, **Pressure**, and **Temperature**. By selecting **Thermal** in the **Analysis** list, you can select the following **Thermal Loads**: **Temperature**, **Heat Flux**, and **Heat Trans Coeff**. Note the following limitations with these loads:

- When the **Energy Equation** is disabled, only the **Structural Loads** options of **Force** and **Pressure** are available.
- Loads are written only on boundary walls when the entire domain is exported (that is, if no **Surfaces** are selected).

Click the **Write...** button to save the file, using the **Select File** dialog box. Ansys Fluent exports an input file that contains Mechanical APDL finite element information including nodes, elements, and loads that can be used to do finite element analysis in Mechanical APDL with minimal effort. The file format is written in `.cdb` format. The export of Mechanical APDL Input files is in ASCII format and therefore is available on all platforms.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See Exporting Data During a Transient Calculation (p. 976) for the complete details.

3.15.3. ASCII Files

Select **ASCII** from the **File Type** drop-down list and choose the surface(s) for which you want to write data in the **Surfaces** list. If no surfaces are selected, the entire domain is exported. Also select the variable(s) for which data is to be saved in the **Quantities** list.

When exporting ASCII files, you have the following options:

- Select the **Location** from which the values of scalar functions are to be taken. If you specify the data **Location** as **Node**, then the data values at the node points are exported. If you choose **Cell Center**, then the data values from the cell centers are exported. For boundary faces, it is the face center values that are exported when the **Cell Center** option is selected.
- Select the **Delimiter** separating the fields (**Comma** or **Space**).

Click the **Write...** button to save the file, using the **Select File** dialog box. Ansys Fluent will export a single ASCII file containing coordinates, optional loads, and specified scalar function data.

Important:

Ansys Fluent supports exporting polyhedral data to ASCII.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See Exporting Data During a Transient Calculation (p. 976) for the complete details.

3.15.4. CDAT for CFD-Post and EnSight

Output from Ansys Fluent simulations can be read into CFD-Post and EnSight. The default output file for Ansys Fluent is a `.dat.h5` file (see Reading and Writing Data Files (p. 933)), which contains raw data directly from the solver; when viewed in CFD-Post and EnSight, such files may show results that are not entirely consistent with what you would see when postprocessing within Fluent (this is even more true for `.dat` files, which also have the limitation that they cannot be read in EnSight). You can instead use `.cdat` files so that the raw data is processed prior to export in order to reduce such inconsistencies.

Note:

- **CDAT for CFD-Post & EnSight** is not available for cases using the **Structural** model. For these cases, export to **Common Fluids Format - Post**.
- One known limitation of `.cdat` files is that they only contain nodal values, even for face zones.
- EnSight Case Gold files (EnSight Case Gold Files (p. 967)) are recommended for the best performance in EnSight, even over `.cdat` files.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To export `.cdat` files, select **CDAT for CFD-Post & EnSight** from the **File Type** drop-down list. Next, specify the **Cell Zones** that contain the data you want exported; note that by default, all of the cell zones will be exported. If you want to export solution data for particular surfaces, then select them from the **Surfaces** list. Once you have chosen your cells zones and/or surfaces you must select the **Quantities** that you want to export. When selecting the variables, be sure to include any variable that was used to create an isosurface or clipped surface (as described in Iso-surfaces (p. 3818) and Clipping Surfaces (p. 3820), respectively); otherwise, the surface will not be created properly if you try to read the exported state file in CFD-Post.

Specify the format of the `.cdat` file by selecting either **Binary** or **ASCII** from the **Format** list. The advantage of the binary format is that it takes less time to load the exported data into Ansys CFD-Post and requires less storage space. Note that the format for the `.cst` will always be ASCII.

Fluent will write a legacy case file (that is, `.cas`) along with the **CDAT for CFD-Post & EnSight** file. This ensures that the data can be read into Ansys CFD-Post.

Click the **Write...** button to save the files, using the **Select File** dialog box. A `.cdat` file is written, containing the specified variable data for the specified cell zones and all of the boundary zones. A state file (that is, `.cst`) is also written, which contains the following surfaces that you created in Fluent for postprocessing: point surfaces, line surfaces, plane surfaces, isosurfaces, and clipped surfaces (see Creating Surfaces and Cell Registers for Displaying and Reporting Data (p. 3793)).

Note:

Imprinted surfaces defined in Ansys Fluent are not available for postprocessing in Ansys CFD-Post.

Important:

When you read the `.cdat` file into Ansys CFD-Post, the application will attempt to read in the case file that produced the data by looking in the folder for a `.cas` file with the same prefix. If such a case file does not exist in that folder, Ansys CFD-Post will prompt you to specify the appropriate case file.

Important:

Before loading the `.cst` file into Ansys CFD-Post, make sure that the `.cas` and `.cdat` files are already loaded for the session.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See Exporting Data During a Transient Calculation (p. 976) for the complete details.

3.15.5. CGNS Files

Select **CGNS** from the **File Type** drop-down list, select the desired cell zone(s) or surface(s), and specify the scalars you want in the **Quantities** list.

Specify the **Format** of the exported file:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **HDF5**—Hierarchical data format, which makes use of built-in compression. It cannot be viewed in a text editor. However, third-party tools are available that allow you to open and explore the contents of files saved in HDF format.
- **ADF**—Legacy format for CGNS file export.

Specify the type of mesh that is exported:

- Mixed: The mesh is exported as CGNS mixed type elements (even if the original mesh is uniform).

  This is set by entering `file/export/settings/cgns-mesh-type 1` in the Console.

- Native: The mesh is exported with the same node ordering as the existing mesh.

  This is set by entering `file/export/settings/cgns-mesh-type 2` in the Console.

  Important:

  Files exported in the native mesh format are usually smaller than those exported in mixed or poly format.

- Polyhedral : The mesh is exported with the same node ordering as the existing mesh.

  This is set by entering `file/export/settings/cgns-mesh-type 3` in the Console.

Refer to https://cgns.github.io/CGNS_docs_current/sids/gridflow.html#element_example for additional information on CGNS mesh types.

Select the **Location** from which the values of scalar functions are to be taken. If you specify the data **Location** as **Node**, then the data values at the node points are exported. If you choose **Cell Center**, then the data values from the cell centers are exported. For boundary faces, it is the face center values that are exported when the **Cell Center** option is selected.

Note:

When you select a zone with more than 30 characters in its name, the name is cutoff and the zone ID is appended to the end of the shortened name. *This character limit is a CGNS standard.*

Click the **Write...** button to save the file, using the **Select File** dialog box. CGNS (CFD general notation system) is a single file (for example, `file.cgns`) containing coordinates, connectivity, zone information, velocity, and selected scalars.

Important:

- Ansys Fluent supports exporting polyhedral data to CGNS.
- (Windows only) You cannot export files larger than 2GB to CGNS in ADF format. There is no size limitation if you export to CGNS in HDF5 format. As a workaround if you required CGNS files in ADF format, use a Linux machine to export files larger than 2GB.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See Exporting Data During a Transient Calculation (p. 976) for the complete details.

3.15.6. Common Fluids Format - Post Files

Output from Ansys Fluent simulations can be read into EnSight. The default output file saved from Ansys Fluent is a `.dat.h5` file (see Reading and Writing Data Files (p. 933)), which contains raw data directly from the solver; when viewed in other applications (such as EnSight and CFD-Post) the results may not be entirely consistent with what you would see when postprocessing within Fluent. This is also true for legacy `.dat` files.

Within Fluent, it is possible to export Common Fluids Format - Post files to reduce such inconsistencies. The data exported to these files is made more consistent by processing the raw data within Fluent before writing the file.

The data written to the Common Fluids Format – Post file, does not contain the full mesh, topology, or physics information that is present within the default Fluent files. Instead, the export can be controlled to restrict the mesh and data to specific surfaces and quantities. This can be useful if you wish to monitor how quantities change across time on just a small subset of the problem domain because the reduced datasets can lead to improved read times.

Note:

- For the best performance in EnSight export to EnSight Case Gold (EnSight Case Gold Files (p. 967)).
- For CFD-Post, export CDAT files if you want to postprocess a full representation of the simulation mesh, topology, and physics used within Fluent with some corrected quantities.
- Common Fluids Format - Post files only contain nodal values, even for face zones, with the exception of cell-related field variables such as Active Cell Partition, Cell Volume Change, and so on, which are indicated with the *cve* code in Field Variables Listed by Category (p. 4137).
- When running on mixed Windows / Linux, you must specify a remote working directory at launch in order to be able to export Common Fluids Format - Post files, by using one of the following: the **Remote Working Directory** option and field in the **Remote** tab of Fluent Launcher; the `-nodehomedir=<directory>` command line option; or the `NODEHOMEDIR=<directory>` environment variable.

Select **Common Fluids Format - Post** from the **File Type** drop-down list and select the cell zone(s) and surface(s) where you want data exported in the **Cell Zones** and **Surfaces** lists, as well as the scalars you want in the **Quantities** list. After you select the cell zones, surfaces, and quantities that you want exported, click **>>** to add the quantity to the list. Click **<<** to remove selected zone/surface and quantities that you do not want exported from the **Quantity List**.

An advantage of exporting in the **Common Fluids Format - Post** is that you can export different quantities on different surfaces/cell zones. For example, you can export shear-stress on a wall surface

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

and pressure on an outlet surface. This provides flexibility to limit the data you are exporting to the surfaces where you are interested in postprocessing those values.

Click the **Write...** button to save the file, using the **Select File** dialog box. The following files are written in the hierarchical data format (HDF) from the **Export** dialog box: `<filename>.cas.post` and `<filename>.dat.post`.

3.15.7. EnSight Case Gold Files

When exporting to EnSight, you can choose to export the data associated with a single data file, or you can export the data associated with multiple files that were generated by a transient solution.

- To export the solution data from a single data file, read in the case and data file and open the **Export** dialog box.

  File → **Export** → **Solution Data...**

  Then perform the following steps in the **Export** dialog box:

  1. Select **EnSight Case Gold** from the **File Type** drop-down list.
  2. Select the **Location** from which the values of scalar functions are to be taken. If you specify the data **Location** as **Node**, then the data values at the node points are exported. If you choose **Cell Center**, then the data values from the cell centers are exported. For boundary faces, it is the face center values that are exported when the **Cell Center** option is selected.
  3. Specify the format of the file by selecting either **Binary** or **ASCII** from the **Format** list. The advantage of the binary format is that it takes less time to load the exported files into EnSight.
  4. (optional) Select the **Cell Zones** from which you want data exported (you must select at least one zone). By default, all of the cell zones are selected.
  5. (optional) Select the **Interior Zone Surfaces** from which you want data exported. By default, the data being exported is taken from the entire Ansys Fluent domain. The **Interior Zone Surfaces** selection list allows you to also specify that the data be taken from selected zone surfaces whose **Type** is identified as **interior** in the **Boundary Conditions** task page.

     Note:

     Data on user defined/created surfaces is not available for export to EnSight Case Gold file format.

  6. Select the scalars you want to write from the **Quantities** selection list.
  7. Click the **Write...** button to open the **Select File** dialog box, which you can use to save a file that contains the specified variable data for the specified cell zones, the specified interior zone surfaces, and all of the boundary zones.

- To export solution data associated with multiple files that were generated by a transient solution, you must first make sure that the following criteria are met:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

– All of the relevant case and data files must be in the working folder.

– The data files must be separated by a consistent number of time steps.

Next, enter the following text command in the console:

`file → transient-export → ensight-gold-from-existing-files`

Then, enter responses to the following prompts in the console:

1. `EnSight Case Gold file name`

   Enter the name you want assigned to the exported files.

2. `Case / Data file selection by base name?`

   Enter `yes` if the case and data files share a "base name" (that is, a common initial string of characters). The alphanumeric order of the full names must correspond to the order in which the files were created. You will then be prompted to enter the base name at the `Case / Data file base name` prompt that follows. For example, with a set of files named `elbow-0001`, `elbow-0002`, `elbow-0003`, and so on, enter `elbow-` for the base name.

   Enter `no` if you have created an ASCII file in the working folder that lists the names of the data files in order of when they were created. The file should list one data file name per line. You will then be prompted to enter the name of this file at the `Provide the file name which contains the data file names` prompt that follows. Note that you must include the file extension if any in your entry at the prompt.

3. `Specify Skip Value`

   Enter an integer value to specify the number of files you want to skip in between exporting files from the sequence. For example, enter `1` to export every other file, enter `2` to export every third file, and so on.

4. `Cell-Centered?`

   Enter `yes` if you want to export the data values from the cell centers (or face center values, for boundary faces).

   Enter `no` if you want to export the data values from the node points.

5. `Write separate file for each time step for each variable?`

   Enter `yes` if you want separate EnSight Case Gold files written for each time step. Otherwise, all of the data for the `.scl1` and `.vel` files will be combined into a single file for each.

6. `Write in binary format?`

   Enter `yes` to write the files in binary format. Otherwise, they will be written in ASCII format. The advantage of the binary format is that it takes less time to load the exported files into EnSight.

7. `Specify Data File Frequency`

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Enter the number of time steps between the data files being exported.

8. `Separate case file for each time step?`

   Enter `no` if all the data files were generated from the same case file (that is, the simulation involved a static mesh). Note that the name of the case file must be the same (not including the extension) as the name of the first data file in the sequence.

   Enter `yes` if the data files were generated from the different case files (that is, the simulation involved a sliding or dynamic mesh). Note that the names of the case files must be the same (not including the extension) as the names of the corresponding data files.

9. `Read the case file?`

   Enter `no` if the first (or only, for a static mesh) case file is already in memory.

   Enter `yes` if the first (or only, for a static mesh) case file is *not* already in memory.

10. `cell zone id/name(1)`

    Enter the name or ID of any cell zone from which you want data exported. By default, the data being exported is taken from the entire Ansys Fluent domain. After you specify the first cell zone, you will be prompted to specify the second one, and so on, until you press **Enter** without typing any characters.

11. `Interior Zone Surfaces(1)`

    Enter the name of any interior zone surface from which you want data exported. By default, the data being exported is taken from the entire Ansys Fluent domain. This prompt allows you to also specify that the data be taken from selected zone surfaces whose **Type** is identified as **interior** in the **Boundary Conditions** task page. After you specify the first interior zone surface, you will be prompted to specify the second one, and so on, until you press **Enter** without typing any characters.

12. `EnSight Case Gold scalar(1) else q to continue`

    Enter in the first scalar quantity you want exported. You can press the **Enter** key to print a list of available scalar quantities in the console. After you enter the first quantity, you will be prompted to enter the second quantity, and so on, until you enter `q`. The EnSight Case Gold files will then be written.

When exporting to EnSight Case Gold, files will be created with the following four formats:

- A geometry file (for example, `file.geo`) containing the coordinates and connectivity information.
- A velocity file (for example, `file.vel`) containing the velocity.
- A scalar file (for example, `file.scl1`) for each selected variable or function.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- An EnSight case file (for example, `file.encas`) that contains details about the other exported files.

Important:

- For non-stationary reference zones, all the velocities are exported to EnSight as velocities relative to the selected reference zone.
- Ansys Fluent supports exporting polyhedral data to EnSight.

Note:

If you are planning to import files exported to EnSight into a non-Ansys third-party post-processing software, such as Paraview, then you must ensure that no surface has an ID of zero. If there is, then create a zone surface for that surface and export the newly created zone surface instead of the original.

You also have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. For details, see Exporting Data During a Transient Calculation (p. 976).

Refer to Transition Assistance from Fluent to EnSight for Post Processing in the *Fluent to EnSight Considerations* for additional guidance on choosing the best format for your case.

3.15.8. EnSight DVS

You can export Fluent solution data in EnSight DVS format. Refer to Transition Assistance from Fluent to EnSight for Post Processing in the *Fluent to EnSight Considerations* for additional guidance on choosing the best format to use in EnSight for your case.

To export in EnSight DVS format:

1. Open the **Export** dialog box.

   File → **Export** → **Solution Data...**

2. Select **EnSight DVS** from the **File Type** drop-down list.
3. Select the desired **Cell Zones** or **Surfaces** (not both), and **Quantities** from their respective lists.

   Note:

   Duplicate surfaces cannot be exported to EnSight.

4. Click **Write...** to open the **Select File** dialog box, so that you can save the **EnSight DVS** files in the preferred location.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3.15.9. FAST Files

This file type is valid only for triangular and tetrahedral meshes. Select **FAST** from the **File Type** drop-down list and select the scalars you want to write in the **Quantities** list.

Click the **Write...** button to save the file for the specified function(s), using the **Select File** dialog box. The following files are written:

- A mesh file in extended Plot3D format containing coordinates and connectivity.
- A velocity file containing the velocity.
- A scalar file for each selected variable or function.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See Exporting Data During a Transient Calculation (p. 976) for the complete details.

3.15.10. FAST Solution Files

This file type is valid only for triangular and tetrahedral meshes. Select **FAST Solution** from the **File Type** drop-down list and click the **Write...** button. A single file is written containing density, velocity, and total energy data.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See Exporting Data During a Transient Calculation (p. 976) for the complete details.

3.15.11. FieldView Unstructured Files

Select **Fieldview Unstructured** from the **File Type** drop-down list. Next, specify the cell zones and surfaces from which you want data exported by making selections in the **Cell Zones** or **Surfaces** lists (you must select at least one zone or surface); note that by default, all of the cell zones will be exported. Then select the scalars you want to write in the **Quantities** list. Finally, click the **Write...** button to open the **Select File** dialog box, which you can use to save a file that contains the specified function(s) for the specified cell zones and associated boundary zones or surfaces.

The following files are written:

- A binary file (for example, `file.fvuns`) containing coordinate and connectivity information and specified scalar function data. In parallel, each partition writes to this file with a grid for each cell zone or surface that is exported. This allows parallel postprocessing in FieldView.
- A regions file (for example, `file.fvuns.fvreg`) containing information about the cell zones or surfaces and the frame of reference. It also includes information about which grids make up the various cell zones or surfaces.

The cell zone and surface information includes the names of the cell zones/surfaces along with the mesh numbers. For the moving frame of reference, the regions file contains information about the origin, the axis of rotation and the rotation speed. Volume data is written using the absolute frame of reference.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If you are running multiple steady-state solutions on the same mesh, you can export only the data files and avoid the repeated writing of the mesh file by using the following TUI command for surfaces and cell zones:

`file/export/fieldview-unstruct-data` *file_name* `(` *list_of_surfaces* `) (` *list_of_zones* `)` *list_of_scalars* `q`

where

- *file_name* specifies the name (without the extension) of the file that you want to write.
- *list_of_surfaces* specifies the list of surfaces (separated by spaces, that is, no commas) from which you want data exported. If you want to specify all of the surfaces, enter `*` within the parentheses.
- *list_of_zones* specifies the list of cell zones (separated by spaces, that is, no commas) from which you want data exported. If you want to specify all of the cell zones, enter `*` within the parentheses.
- *list_of_scalars* specifies the list of cell functions (separated by spaces, that is, no commas) that you want to write to the exported file. The `q` input terminates the list. For example, the input `x-velocity cell-zone q` will select x velocity and the cell volume.

To export only the data files for surfaces, use the following TUI command:

`file/export/fieldview-unstruct-surfaces 2` *file_name* `(` *list_of_surfaces* `)` *list_of_scalars* `q`

where

- `2` specifies that you want to write a Fieldview unstructured results only file.
- *file_name* specifies the name (without the extension) of the file that you want to write.
- *list_of_surfaces* specifies the list of surfaces (separated by spaces, that is, no commas) from which you want data exported. If you want to specify all of the surfaces, enter `*` within the parentheses.
- *list_of_scalars* specifies the list of cell functions (separated by spaces, that is, no commas) that you want to write to the exported file. The `q` input terminates the list. For example, the input `x-velocity q` will select only the x velocity.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See Exporting Data During a Transient Calculation (p. 976) for the complete details.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3.15.12. NASTRAN Files

Select **NASTRAN** from the **File Type** drop-down list. Select the surface(s) containing the data you want to export in the **Surfaces** list. If you do not select any surfaces, the entire domain is exported. You can specify which scalars you want in the **Quantities** list.

Note:

If you are exporting data on a polyhedral mesh, only zone surfaces will be available for selection (no volumetric data or user-defined surfaces).

You have the option of selecting loads to be included in the exported file. When the **Energy Equation** is enabled in the Energy Dialog Box (p. 4662), you can choose the loads based on the kind of finite element analysis you intend to undertake. By selecting **Structural** in the **Analysis** list, you can select the following **Structural Loads**: **Force**, **Pressure**, and **Temperature**. By selecting **Thermal** in the **Analysis** list, you can select the following **Thermal Loads**: **Temperature**, **Heat Flux**, and **Heat Trans Coeff**.

These loads have the following limitations :

- When the **Energy Equation** is disabled, only the **Structural Loads** options of **Force** and **Pressure** are available.
- Loads are written only on boundary walls when the entire domain is exported (that is, if no **Surfaces** are selected).

Click the **Write...** button to save the file, using the **Select File** dialog box. A single file (for example, `file.bdf`) is written containing coordinates, connectivity, optional loads, zone groups, and velocity. Pressure is written as PLOAD4, and heat flux is written as QHBDYE data. If you select wall zones in the **Surfaces** list, nodal forces are written for the walls. When data is written for the heat transfer coefficient, it is based on the wall faces rather than the nodes.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. For details, see Exporting Data During a Transient Calculation (p. 976).

3.15.13. TAITherm Files

The option to export a TAITherm file type is available only when the **Energy Equation** is enabled in the Energy Dialog Box (p. 4662). Select **TAITherm** from the **File Type** drop-down list and select the surface(s) for which you want to write data in the **Surfaces** list. If no surfaces are selected, the entire domain is exported. If the mesh contains polyhedral cells, Ansys Fluent will export only boundary data. No volume data will be exported.

Select the method of writing the heat transfer coefficient (**Heat Transfer Coefficient**), which can be **Flux Based** or, if a turbulence model is enabled, **Wall Function** based. The flux-based heat transfer coefficient is calculated using Equation 7.123 (p. 1458). If no turbulence model is enabled, the wall-function based heat transfer coefficient is calculated as k/h, where k is the thermal conductivity, and h is the cell height of the wall-adjacent cell.

Click the **Write...** button to save the file, using the **Select File** dialog box. A PATRAN neutral file (for example, `file.neu`) is written containing element velocity components (that is, the element that

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

is just touching the wall), heat transfer coefficients, and temperatures of the wall for any selected wall surface. If the wall is one-sided, the data is written for one side of the wall. If the wall is two-sided (a wall-wall shadow pair), the values are written only for the original wall face, not for the shadow face (which is a duplicate).

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See Exporting Data During a Transient Calculation (p. 976) for the complete details.

Note:

If no turbulence model is enabled, the **Wall Function** based Heat Transfer Coefficient is equal to k/h, where k is the thermal conductivity, and h is the cell height of the wall-adjacent cell.

3.15.14. Tecplot Files

Select **Tecplot** from the **File Type** drop-down list and choose the surface(s) where you want data written in the **Surfaces** list. *If no surfaces are selected, the data is exported at cell centers for the entire domain. If surfaces are selected, the data is exported on their face centers*. Select the variable(s) you want exported in the **Quantities** list.

Click the **Write...** button to save the file, using the **Select File** dialog box. A single file is written containing the coordinates and scalar functions in the appropriate tabular format.

Important:

- The **utility fe2ram** can import Tecplot files only in **FEPOINT** format.
- If you intend to postprocess Ansys Fluent data with Tecplot, you can either export data from Ansys Fluent and import it into Tecplot, or use the Tecplot Ansys Fluent Data Loader included with your Tecplot distribution. The data loader reads native Ansys Fluent case and data files directly. If you are interested in this option, contact Tecplot, Inc. for assistance or visit www.tecplot.com.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See Exporting Data During a Transient Calculation (p. 976) for the complete details.

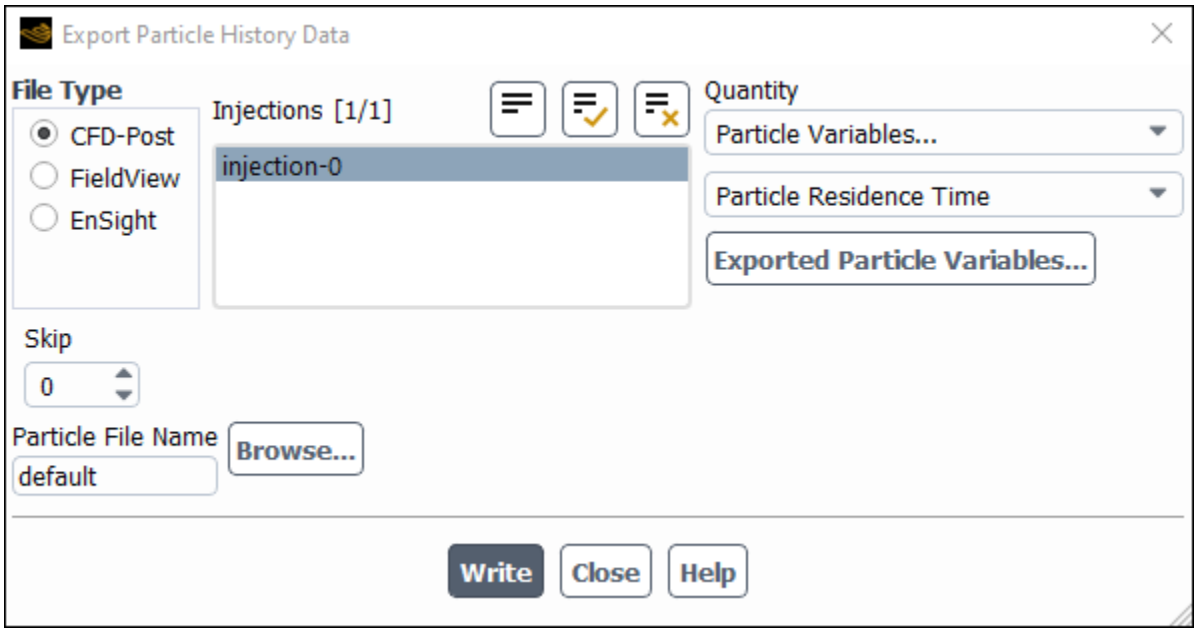
3.16. Exporting Steady-State Particle History Data

Particle history data can be exported for steady-state solutions or for single transient particle steps by selecting the **Particle History Data...** option under the **File/Export** ribbon tab and performing the steps described in this section. For details about exporting particle history data automatically during transient simulations, see Creating Automatic Export Definitions for Transient Particle History Data (p. 979).

File → Export → Particle History Data...

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 3.10: The Export Particle History Data Dialog Box



1. Specify the **File Type** you want to export by selecting one of the following:

   - **CFD-Post** for the CFD-Post compatible format
   - **FieldView** for the FIELDVIEW format
   - **EnSight** for the EnSight format
   - **Geometry** for the `.ibl` format (not available when **Unsteady Particle Tracking** is enabled in the **Discrete Phase Model** dialog box)

   Important:

   If you plan to export particle data to EnSight, you should first verify that you have already written the files associated with the EnSight Case Gold file type by using the **File/Export/Solution Data...** ribbon tab option (see EnSight Case Gold Files (p. 967)).

   Select the predefined injections that are the source of the particles from the **Injections** selection list. See Creating and Modifying Injections (p. 2751) for details about creating injections.

2. Select the particle variables contained in the export file by clicking the **Exported Particle Variables...** button and selecting the variables appearing in the **Reporting Variables** dialog box (Figure 23.68: The Reporting Variables Dialog Box (p. 2852)), as described in Reporting of Current Positions for Unsteady Tracking (p. 2854). Note that although the variable **Particle Residence Time** does not appear in the **Available Particle Variables** selection list, it is always exported.

3. If you have added the **Color by** variable in the **Reporting Variables** dialog box, select an appropriate category and variable under **Quantity** for the particle data to be exported.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. If your exported particle history file is too large to postprocess because there are too many tracks or particles written to the file, you can reduce the number of particle tracks by increasing the **Skip** value.

5. To control the exported file size, the number of points of the particle trajectories can be reduced using the **Coarsen** value. This is only valid for steady-state particle trajectories.

   When exporting to an EnSight file, you can use this value to reduce the temporary file size written during tracking with a small effect on accuracy of the trajectory. The number of steps per trajectory finally exported to the EnSight file is the same as the **Number of Particle Time Steps**.

6. Enter the name (and folder path, if you do not want it to be written in the current folder) for the exported particle data file in the **Particle File Name** text box. Alternatively, you can specify it through the **Select File** dialog box, which is opened by clicking the **Browse...** button.

7. If you selected **EnSight** under **File Type**, you should specify the **EnSight Encas File Name**. Use the **Browse...** button to select the `.encas` file that was created when you exported the file with the **File/Export/Solution Data...** ribbon tab option. The selected file will be modified and renamed as a new file that contains information about all of the related particle files that are generated during the export process (including geometry, velocity, scalars, particle and particle scalar files).

   The name of the new file will be the root of the original file with `.new` appended to it (for example, if `test.encas` is selected, a file named `test.new.encas` will be written). It is this new file that should be read into EnSight. If you do not specify a **EnSight Encas File Name**, then you must create an appropriate `.encas` file manually.

8. If you selected **EnSight** under **File Type**, and you are exporting steady-state particle tracks, enter the **Number of Particle Time Steps**.

9. Click **Write** to export the particle history data. If you selected **EnSight** under **File Type**, data files will be written in both `.mpg` and `.mscl` formats.

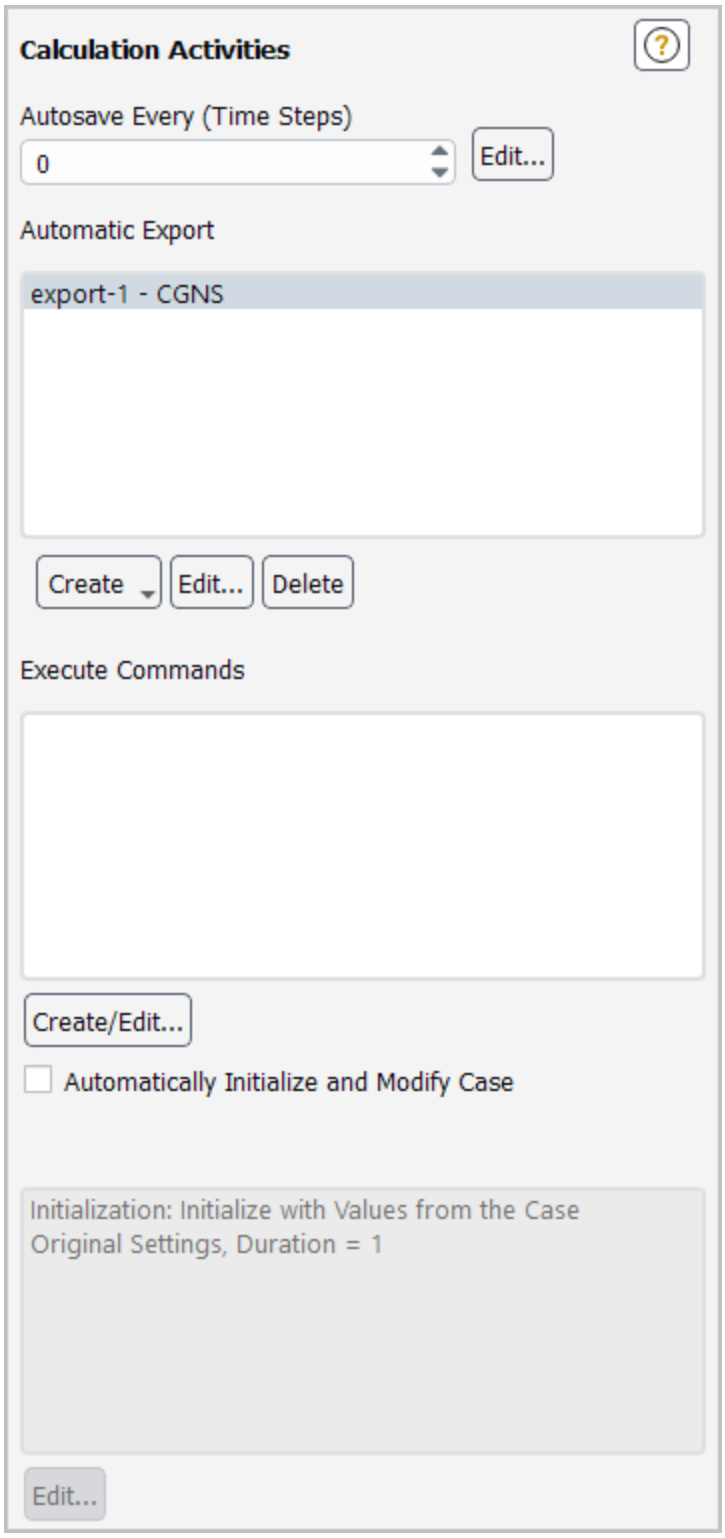
10. Click **Close** to close the dialog box.

3.17. Exporting Data During a Transient Calculation

Before you run a transient flow solution, you can set up the case file so that solution data and particle history data is exported as the calculation progresses. This is accomplished by creating automatic export definitions using the Calculation Activities Task Page (p. 5134) (Figure 3.11: The Calculation Activities Task Page (p. 977)), as described in the following sections.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 3.11: The Calculation Activities Task Page



The names of the automatic export definitions you create are displayed in the **Automatic Export** selection list, along with the format in which it will be exported. You can edit or delete the definition by selecting a definition in the list and clicking the **Edit...** or **Delete** button,.

For additional information, see the following sections:

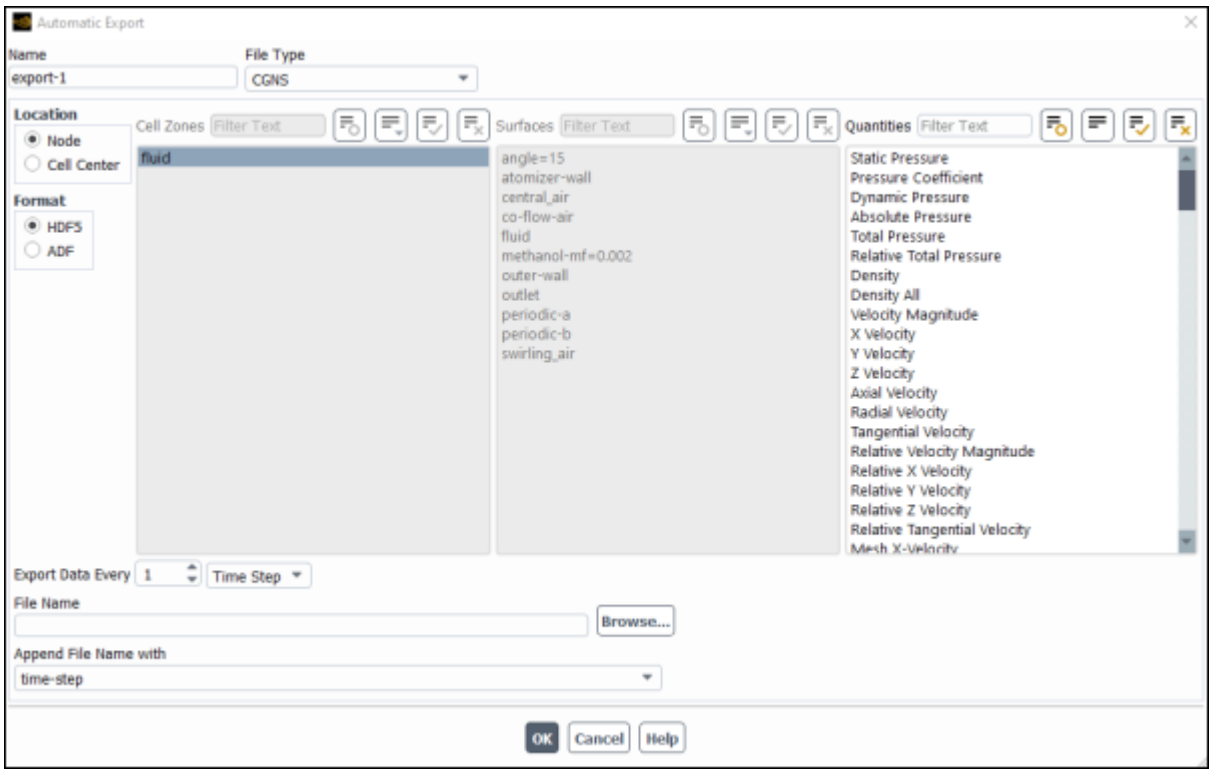
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3.17.1. Creating Automatic Export Definitions for Solution Data
3.17.2. Creating Automatic Export Definitions for Transient Particle History Data

3.17.1. Creating Automatic Export Definitions for Solution Data

To create an automatic export definition for solution data, begin by making sure that **Transient** is selected for **Time** in the General Task Page (p. 4632). Next, click the **Create** button under the **Automatic Export** selection list in the **Calculation Activities** task page (a drop-down list will appear). Select **Solution Data Export...** from the drop-down list to open the **Automatic Export** dialog box (Figure 3.12: The Automatic Export Dialog Box (p. 978)).

Figure 3.12: The Automatic Export Dialog Box



Then perform the following steps:

1. Enter a name for the automatic export definition in the **Name** text box. This is the name that will be displayed in the **Automatic Export** selection list in the **Calculation Activities** task page.

2. Define the data to be exported by making selections in the relevant group boxes and selection lists: **File Type**, **Cell Zones**, **Surfaces**, **Interior Zone Surfaces**, **Quantities**, **Analysis**, **Structural Loads**, **Thermal Loads**, **Location**, **Delimiter**, **Format**, and **Heat Transfer Coefficient**. See ABAQUS Files (p. 962) – Tecplot Files (p. 974) for details about the specific options available for the various file types.

3. Set the frequency at which the solution data will be exported during the calculation using the **Export Data Every** field and specify whether you want the save rate based on **Time Steps** or **Flow Time**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. If you selected **EnSight Case Gold** from the **File Type** drop-down list, the **Separate Files for Each Time Step** option allows you to specify that separate files are written at the prescribed time steps. This option is enabled by default and is the recommended practice, as it ensures that all of the data is not lost if there is a disruption to the calculation (for example, from a network failure) before it is complete. If you choose to disable this option, all of the data for the `.scl1` and `.vel` files will be combined into a single file for each.

5. If you selected **CDAT for CFD-Post & EnSight** from the **File Type** drop-down list, by default Ansys Fluent will save a legacy case file (`.cas`) with every `.cdat` file (that is, at the specified **Frequency**), but you have the option of picking **Only if Case/Mesh Changes**, which can reduce the total space required to save all files associated with this export. A single `.cst` file will also be written when exporting during a transient calculation.

   For more information about the **CDAT for CFD-Post & EnSight** file type, refer to CDAT for CFD-Post and EnSight (p. 963).

6. Specify how the exported files will be named. Every file saved will begin with the characters entered in the **File Name** text box (note that a file extension is not necessary). You can specify a folder path if you do not want it written in the current folder. The **File Name** can also be specified through the **Select File** dialog box, which is opened by clicking the **Browse...** button.

   Next, make a selection in the **Append File Name with** drop-down list, to specify that the **File Name** be followed by either the time step number or flow time at which it was saved. Note that this selection is not available when exporting to EnSight. When **EnSight Case Gold** is selected from the **File Type** drop-down list, the time step number is always appended if the **Separate Files for Each Time Step** option is enabled; otherwise, no digits are appended.

   When appending the file name with the flow time, you can specify the number of decimal places that will be used by making an entry in the **Decimal Places in File Name** text box. By default, six decimal places will be used.

7. Click **OK** to save the settings for the automatic export definition.

For details about general limitations for exporting solution data and the manner in which it is exported, see Exporting Solution Data (p. 959).

Important:

If the files that are exported during multiple transient simulations are to be used as a set, you should run all of the simulations on the same platform, using the same number of processors. This ensures that all of the files are compatible with each other.

Note that if you selected **EnSight Case Gold** from the **File Type** drop-down list, Ansys Fluent does not support exporting data files to EnSight during a transient calculation in which a new cell zone or surface is created after the calculation has begun (as can be the case for an in-cylinder simulation, for example).

3.17.2. Creating Automatic Export Definitions for Transient Particle History Data

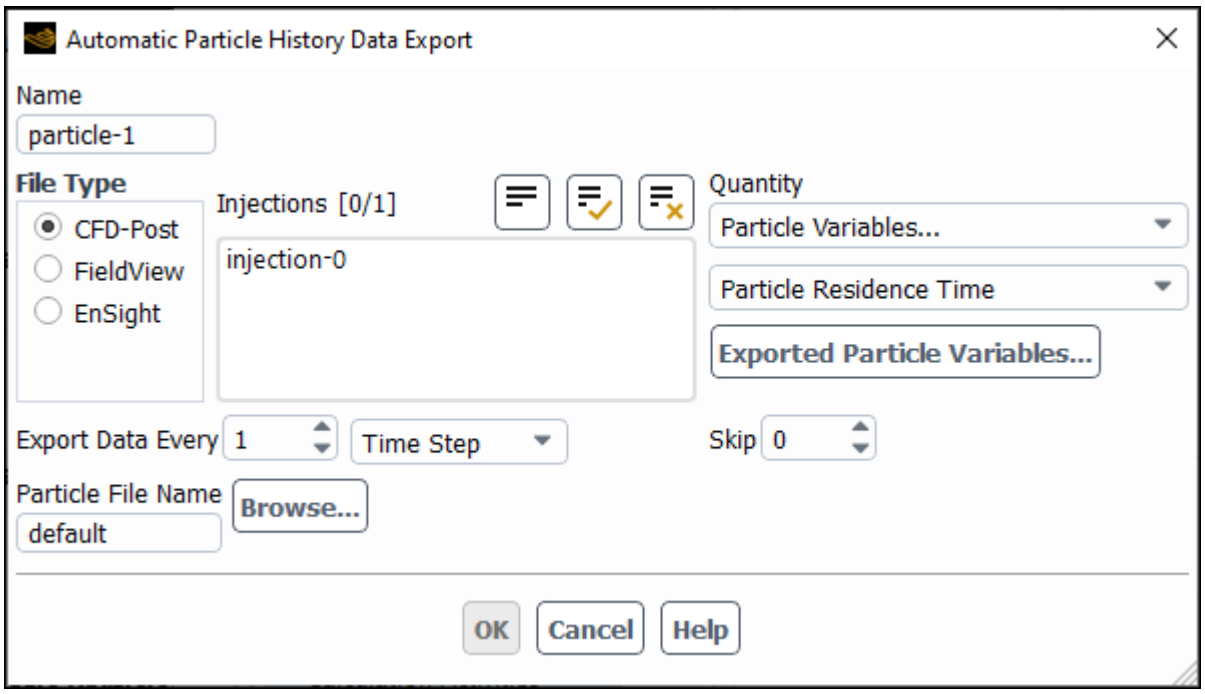
To create an automatic export definition for particle history data:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Make sure that **Unsteady Particle Tracking** is selected in the **Discrete Phase Model** dialog box.

2. In the **Calculation Activities** task page, under the **Automatic Export** selection list, click the **Create** drop-down list and select **Particle History Data Export...** to open the **Automatic Particle History Data Export** dialog box (Figure 3.13: The Automatic Particle History Data Export Dialog Box (p. 980)).

   Figure 3.13: The Automatic Particle History Data Export Dialog Box



3. Enter a name for the automatic export definition in the **Name** text box. This is the name that will be displayed in the **Automatic Export** selection list in the **Calculation Activities** task page. Make sure that the chosen name is not already used for another **Automatic Export**.

4. Choose the **File Type** you want to export by selecting one of the following:

   - **CFD-Post** for the CFD-Post compatible format
   - **FieldView** for the FIELDVIEW format
   - **EnSight** for the EnSight format

   Important:

   If you plan to export particle data to EnSight, you should first set up an automatic export definition so that solution data is also exported to EnSight during this calculation (see Creating Automatic Export Definitions for Solution Data (p. 978)). As described in the steps that follow, some of the settings must correspond between the two automatic export definitions.

5. Select the predefined injections that are the source of the particles from the **Injections** selection list. See Creating and Modifying Injections (p. 2751) for details about creating injections.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. Select the particle variables contained in the export file by clicking the **Exported Particle Variables...** button and selecting the variables appearing in the **Reporting Variables** dialog box (Figure 23.68: The Reporting Variables Dialog Box (p. 2852)), as described in Reporting of Current Positions for Unsteady Tracking (p. 2854). Note that although the variable **Particle Residence Time** does not appear in the **Available Particle Variables** selection list, it is always exported.

7. If you have added the **Color by** variable in the **Reporting Variables** dialog box, select an appropriate category and variable under **Quantity** for the particle data to be exported.

8. In the **Export Data Every** integer number entry box, specify the frequency for appending the data during the solution process. You can export particle history data frequency based on either **Time Step** or **Flow Time** for unsteady flow cases, or based on **DPM Iteration** for steady flow cases.

9. If your exported particle history file is too large to postprocess because there are too many tracks or particles written to the file, you can reduce the number of particle tracks by increasing the **Skip** value.

10. If you selected **EnSight Case Gold** for the **File Type**, the **Separate Files for Each Time Step** option allows you to specify that separate files are written at the prescribed time steps. This option is enabled by default and is the recommended practice, as it ensures that all of the data is not lost if there is a disruption to the calculation (for example, from a network failure) before it is complete. If you choose to disable this option, all of the data for the `.mscl` and `.mpg` files will be combined into a single file for each.

    Important:

    The setting for the **Separate Files for Each Time Step** option should be the same (that is, enabled or disabled) as that of the automatic export definition you set up to export solution data to EnSight during this calculation. For details, see Creating Automatic Export Definitions for Solution Data (p. 978).

11. Enter the name (and folder path, if you do not want it to be written in the current folder) for the exported particle data file in the **Particle File Name** text box. Alternatively, you can specify it through the **Select File** dialog box, which is opened by clicking the **Browse...** button. Make sure the file name is different from other existing **Automatic Export** definitions to avoid overwriting data.

    If you selected **FieldView** under **File Type**, you can write particle history data for each time step to separate files by including the character string `%t` in the particle file name. At the time of export, Fluent will substitute `%t` with the current time step number. The saved files can be processed by FieldView 14 or newer.

12. If you selected **EnSight** under **File Type**, you should specify the **EnSight Encas File Name**. Enter the same name (and folder path, if necessary) that you entered in the **File Name** text box when you set up the automatic export definition for exporting solution data to EnSight during this calculation. (For details, see Creating Automatic Export Definitions for Solution Data (p. 978)). The `.encas` file created during the solution data export will be modified and renamed as a new file that contains information about all of the related particle files that are generated after every time step during the export process (including geometry, velocity, scalars, particle and particle scalar files). The name of the new file will be the root of the original `.encas` file with `.new` appended

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

to it (for example, if the solution data export creates `test.encas`, a file named `test.new.encas` will be written for the particle data export). It is this new file that should be read into EnSight.

Important:

If you do not specify an **EnSight Encas File Name**, you will have to manually create an appropriate `.encas` file.

13. Click **OK** to save the settings for the automatic export definition.

The particle data will be exported as it is generated during the transient calculation. If you selected **EnSight** under **File Type**, data files will be written in both `.mpg` and `.mscl` formats.

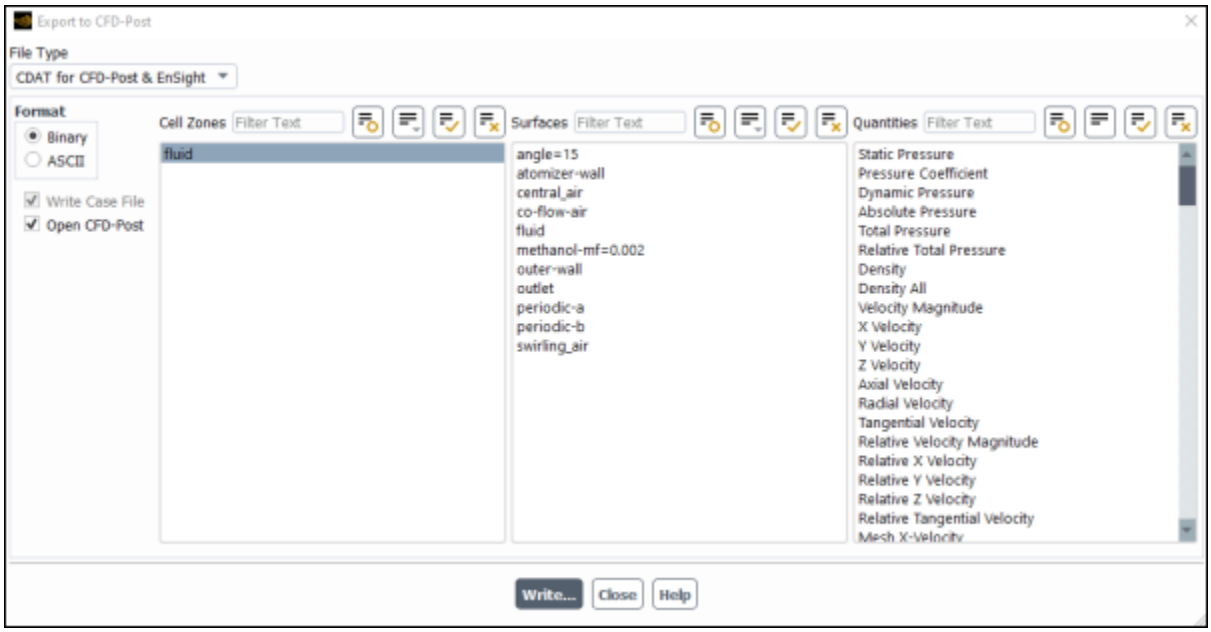
3.18. Exporting to Ansys CFD-Post

You can use the **Export to CFD-Post** dialog box (Figure 3.14: The Export to CFD-Post Dialog Box (p. 982)) to export the results from cell zones and/or surfaces to files that are compatible with Ansys CFD-Post (and EnSight).

For instructions on exporting variables in Ansys CFD-Post compatible file format (`.cdat`) using this dialog box, see CDAT for CFD-Post and EnSight (p. 963).

File → Export to CFD-Post...

Figure 3.14: The Export to CFD-Post Dialog Box



By default, the **Open CFD-Post** option is enabled so that the following actions will occur after the files are exported:

1. A CFD-Post session opens automatically.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. The case and `.cdat` files are loaded in CFD-Post.

3. CFD-Post displays the results.

If you disable the **Open CFD-Post** option, you can open CFD-Post manually and use the **Load Results** item in the **File** drop-down menu to load the results files. For more information about this feature in CFD-Post, see the separate Ansys CFD-Post manual.

Note:

- When exporting to CFD-Post, Fluent only saves a new case file if the mesh or case has changed since the last time the case file was saved, which conserves storage space.
- CFD-Post may have difficulty reading transient cases that have changing mesh topology and/or zones added/removed during the simulation.

3.19. Parallel Exporting to Ansys EnSight

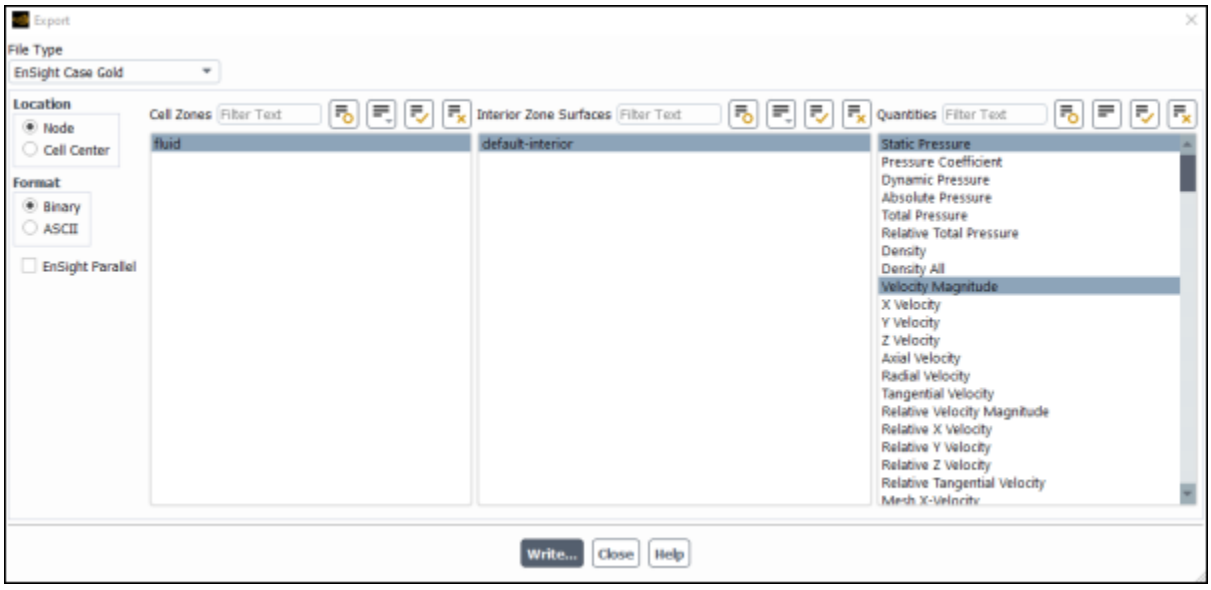
Using the **EnSight Parallel** option in the **Export** dialog box you can save Fluent solution case and data files for postprocessing in Ansys EnSight Enterprise (EnSight in parallel).

To setup parallel EnSight export in Fluent:

1. Ensure that you are running Fluent in parallel. *This functionality is only available when Fluent is running in parallel.*

2. Open the **Export** dialog box.

   File → **Export** → **Solution Data...**



3. Select **EnSight Case Gold** from the **File Type** drop-down.

4. Select either **Node** or **Cell Center** for the **Location** where the data will be written.
5. Select the **Format** for how the data will be saved.
6. Enable **EnSight Parallel**.
7. Select either the **Cell Zones** or **Surfaces** that you want to export.
8. Select the **Quantities** that you want to export.
9. Click **Write...** to specify the location where the data will be saved.

Note that you can also setup for automatic exporting of solution data using the same steps as described above but using the Automatic Export Dialog Box (p. 5139).

Important:

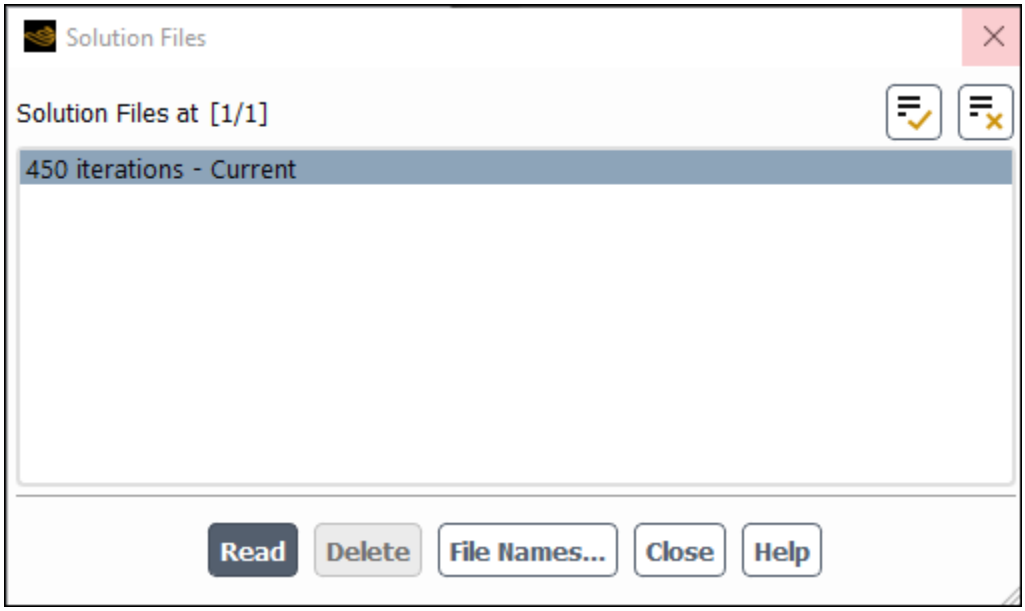
You can either export solution data from **Cell Zones** or **Surfaces**, but you cannot do both at once.

3.20. Managing Solution Files

You can manage your solution files effectively and efficiently using the **Solution Files** dialog box. Here, you can select previously saved files created using the **Autosave** dialog box and read or delete them.

File → Solution Files...

Figure 3.15: The Solution Files Dialog Box



The **Solution Files** dialog box (Figure 3.15: The Solution Files Dialog Box (p. 984)) lists all of the solution files that have been automatically saved. They are listed by iteration number or time step/flow time. For the file that is currently read in, the status of `current` will appear in the **Solution Files at** list. You can make any of the files in the list current by clicking the **Read** button. Note that if more than one file

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

is selected, the **Read** button is disabled. When an earlier solution is made current, the solution files that were generated for a later iteration/time step will be removed from this list when the calculation continues.

You can delete solution files by selecting an entry in the list and clicking **Delete**. Note that a currently loaded solution file cannot be deleted, however multiple (non-current) files can be selected and deleted. If multiple files are selected and one of those files is a currently loaded solution file, clicking **Delete** will result in the current solution file being skipped.

You can click the **File Names...** button to obtain information about the solution files and the path of the associated files.

When running Fluent under Workbench, you can recover the latest case and data files from the system folder (`<project name>\dp0\FFF\Fluent\` for analysis system and `<project name>\dp0\FLU \Fluent\` for component system) by clicking **Recover Missing Solution...** The recovered files will appear in the **Solution Files at** list. You can use this option when the latest matching/compatible case and data files are missing from the **Solution Files at** list.

The **Solution Files** dialog box is particularly useful for reading in files that were saved during the autosave session, since case and data files may not necessarily have the same file name.

3.21. Mesh-to-Mesh Solution Interpolation

Ansys Fluent can interpolate solution data for a given geometry from one mesh to another, allowing you to compute a solution using one mesh (for example, hexahedral) and then change to another mesh (for example, hybrid) and continue the calculation using the first solution as a starting point.

Important:

Ansys Fluent does zeroth-order interpolation for interpolating the solution data from one mesh to another.

For additional information, see the following sections:

3.21.1. Performing Mesh-to-Mesh Solution Interpolation

3.21.2. Format of the Interpolation File

3.21.1. Performing Mesh-to-Mesh Solution Interpolation

The procedure for mesh-to-mesh solution interpolation is as follows:

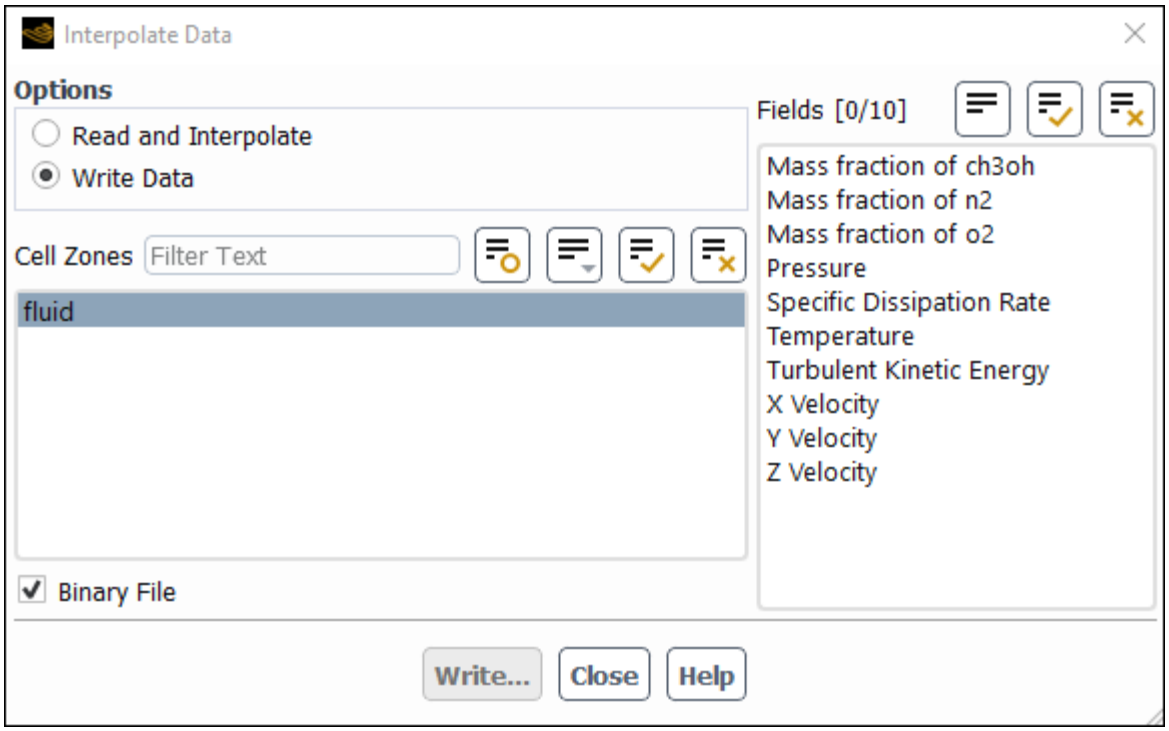
1. Set up the model and calculate a solution on the initial mesh.

2. Write an interpolation file for the solution data to be interpolated onto the new mesh, using the **Interpolate Data** dialog box (Figure 3.16: The Interpolate Data Dialog Box (p. 986)).

   File → Interpolate...

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 3.16: The Interpolate Data Dialog Box



a. Under **Options**, select **Write Data**.

b. In the **Cell Zones** selection list, select the cell zones for which you want to save data to be interpolated.

> **Note:**
>
> If your case includes both fluid and solid zones, write the data for the fluid zones and the data for the solid zones to separate files.

c. Select the variable(s) for which you want to interpolate data in the **Fields** selection list. All Ansys Fluent solution variables are available for interpolation.

d. Select the **Binary File** check box if you want a binary interpolation file to be generated.

> **Note:**
>
> Writing a binary interpolation file is significantly faster and requires less memory than writing a text file.

e. Click **Write...** and specify the interpolation file name in the resulting **Select File** dialog box. The file format is described in Format of the Interpolation File (p. 987).

3. Set up a new case.

   a. Read in the new mesh, using the appropriate ribbon tab item (**File/Read/** or **File/Import/**).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

b. Define the appropriate models.

Important:

Enable all of the models that were enabled in the original case. For example, if the energy equation was enabled in the original case and you forget to enable it in the new case, the temperature data in the interpolation file will not be interpolated.

c. Define the boundary conditions, material properties, and so on.

Important:

An alternative way to set up the new case is to save the boundary conditions from the original model using the `write-settings` text command, and then read in those boundary conditions with the new mesh using the `read-settings` text command. See Reading and Writing Boundary Conditions (p. 946) for further details.

4. Read in the data to be interpolated.

File → **Interpolate...**

a. Under **Options**, select **Read and Interpolate**.

b. In the **Cell Zones** list, select the cell zones for which you want to read and interpolate data.

If the solution has not been initialized, computed, or read, all zones in the **Cell Zones** list are selected by default, to ensure that no zone remains without data after the interpolation. If all zones already have data (from initialization or a previously computed or read solution), select a subset of the **Cell Zones** to read and interpolate data onto a specific zone (or zones).

c. Click the **Read...** button and specify the interpolation file name in the resulting **Select File** dialog box.

Important:

If your case includes both fluid and solid zones, the two sets of data are saved to separate files. Hence perform these steps twice, once to interpolate the data for the fluid zones and once to interpolate the data for the solid zones.

5. Reduce the under-relaxation factors and calculate on the new mesh for a few iterations to avoid sudden changes due to any imbalance of fluxes after interpolation. Then increase the under-relaxation factors and compute a solution on the new mesh.

3.21.2. Format of the Interpolation File

An example of an interpolation file is shown below:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
3
2
34800
3
x-velocity
pressure
y-velocity
(-0.068062
-0.0680413
...
```

The format of the interpolation file is as follows:

- The first line is the interpolation file version. It is 2 for files generated using Ansys Fluent 12.0 through 14.0, 3 for text files generated using Ansys Fluent 14.5, 4 for binary files generated using single precision Ansys Fluent 14.5, and 5 for files generated using double precision Ansys Fluent 14.5.
- The second line is the dimension (2 or 3).
- The third line is the total number of points.
- The fourth line is the total number of fields (temperature, pressure, and so on) included.
- Starting at the fifth line is a list of field names. To see a complete list of the field names used by Ansys Fluent, enter the `display/contour` text command and view the available choices by pressing **Enter** at the `contours of>` prompt. The list depends on the models turned on.
- After the field names is a section for each list of x, y, and (in 3D) z coordinates for all the data points.
- At the end is a section for each list of the field values at all the points in the same order as their names. The number of coordinate and field points should match the number given in line 3.
- For version 3 interpolation files, the sections are bounded by "(" and ")".
- For version 4 and 5 interpolation files, the sections are bounded by "(" and "\nEnd of Binary Section 0)".
- The delimiters help skip a section if the associated model is not enabled. With version 2 interpolation files (where the delimiters do not exist), sections may not be skipped properly if the size of the field cannot be determined without enabling the associated model. This may result in incorrect interpolation of the subsequent field variables.

Important:

An interpolation file written with Ansys Fluent 14.5 and above is not readable in prior versions of Ansys Fluent.

3.22. Mapping Data for Fluid-Structure Interaction (FSI) Applications

Ansys Fluent allows you to map variables (for example, temperature, pressure) from the cell or face zones of an Ansys Fluent simulation onto locations associated with a finite element analysis (FEA) mesh.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The results are written to a file for inclusion into an FEA simulation. During this process, both the original and the new mesh can be viewed simultaneously. Ansys Fluent maps the data using zeroth-order interpolation, and can write the output file in a variety of formats.

This capability is useful when solving fluid-structure interaction (FSI) problems, and allows you to perform further analysis on the solid portion of your model using FEA software. Mapping the data may be preferable to simply exporting the Ansys Fluent data file (as described in Exporting Solution Data (p. 959)), since the meshes used in CFD analysis are typically finer than those used in finite element analysis.

For additional information, see the following sections:

3.22.1. FEA File Formats

3.22.2. Using the FSI Mapping Dialog Boxes

3.22.1. FEA File Formats

The FEA software types that are compatible with Ansys Fluent's FSI mapping capability include ABAQUS, I-deas, ANSYS, NASTRAN, and PATRAN. For details about the kinds of files that can be read or written during this process, see Table 3.2: FEA File Extensions for FSI Mapping (p. 989).

Table 3.2: FEA File Extensions for FSI Mapping

Type	Input File	Output File
ABAQUS	`.inp`	`.inp`
I-deas	`.unv`	`.unv`
ANSYS	`.cdb`, `.neu`	`.cdb`
NASTRAN	`.bdf`	`.bdf`
PATRAN	`.neu`, `.out`, `.pat`	`.out`

3.22.2. Using the FSI Mapping Dialog Boxes

To begin the process of mapping Ansys Fluent data, you must first create a mesh file that can be used as the input file in the steps that follow. The resolution of the mesh should be appropriate for your eventual finite element analysis. You are free to use the method and preprocessor of your choice in the creation of this file, but the end result must correspond to one of the entries in the Input File column of Table 3.2: FEA File Extensions for FSI Mapping (p. 989).

When creating the input file, note the following:

- While the input file may be scaled when it is read into Ansys Fluent, the volumes or surfaces on which the data is to be mapped must otherwise be spatially coincident with their counterparts in the Ansys Fluent simulation.
- Ansys Fluent can map volume and surface data only for 3D cases; data mapping is not supported for 2D cases since data mapping for edges is not supported.
- The input file can be only a portion of the overall FEA model (that is, you can exclude the parts of the model on which you are not mapping Ansys Fluent data). When this is the case, note that the numbering of the nodes and elements in the input file must match the numbering of the nodes and elements in the complete file you will use for your finite element analysis.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Next, read a case file in Ansys Fluent and make sure data is available for mapping, either by running the calculation or by reading a data file.

Finally, perform the following steps to generate an output file in which the Ansys Fluent data has been mapped to the mesh of the input file:

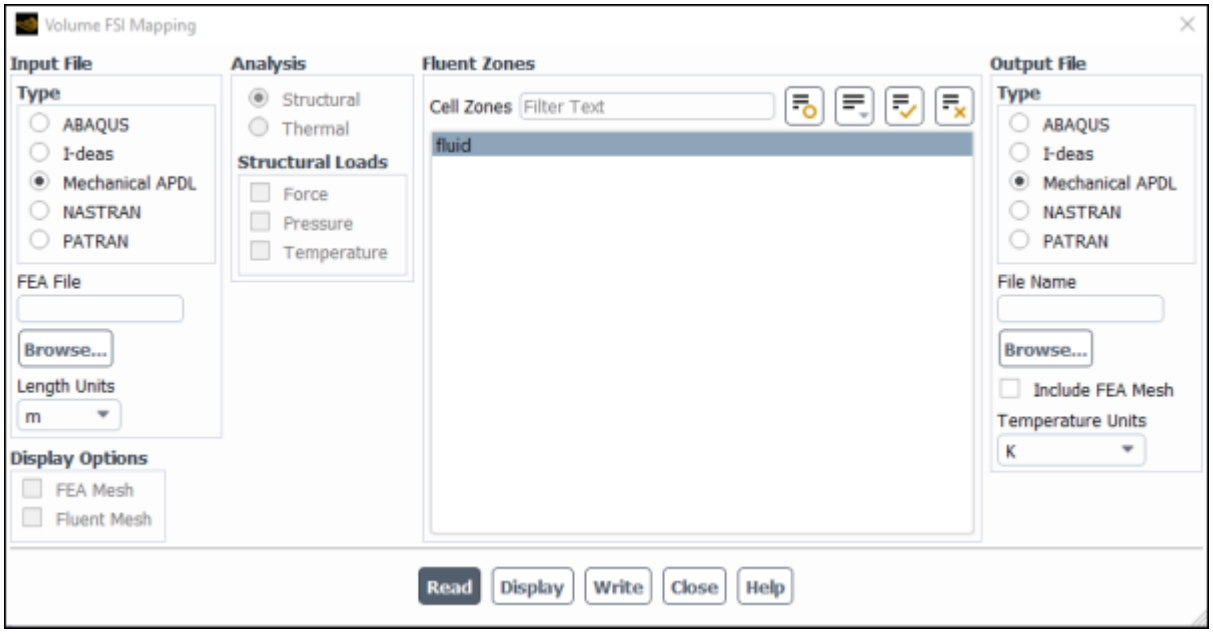
1. Open the Ansys Fluent dialog box that is appropriate for the zones from which the data is to be taken. If the data you are mapping is from a volume (for example, the cell zone of a solid region), open the **Volume FSI Mapping** dialog box using the **File/FSI Mapping/Volume...** ribbon tab item (Figure 3.17: The Volume FSI Mapping Dialog Box for Cell Zone Data (p. 990)). If instead the data is from a surface (for example, a face boundary zone), open the **Surface FSI Mapping** dialog box using the **File/FSI Mapping/Surface...** ribbon tab item (Figure 3.18: The Surface FSI Mapping Dialog Box for Face Zone Data (p. 991)).

   File → FSI Mapping → Volume...

   or

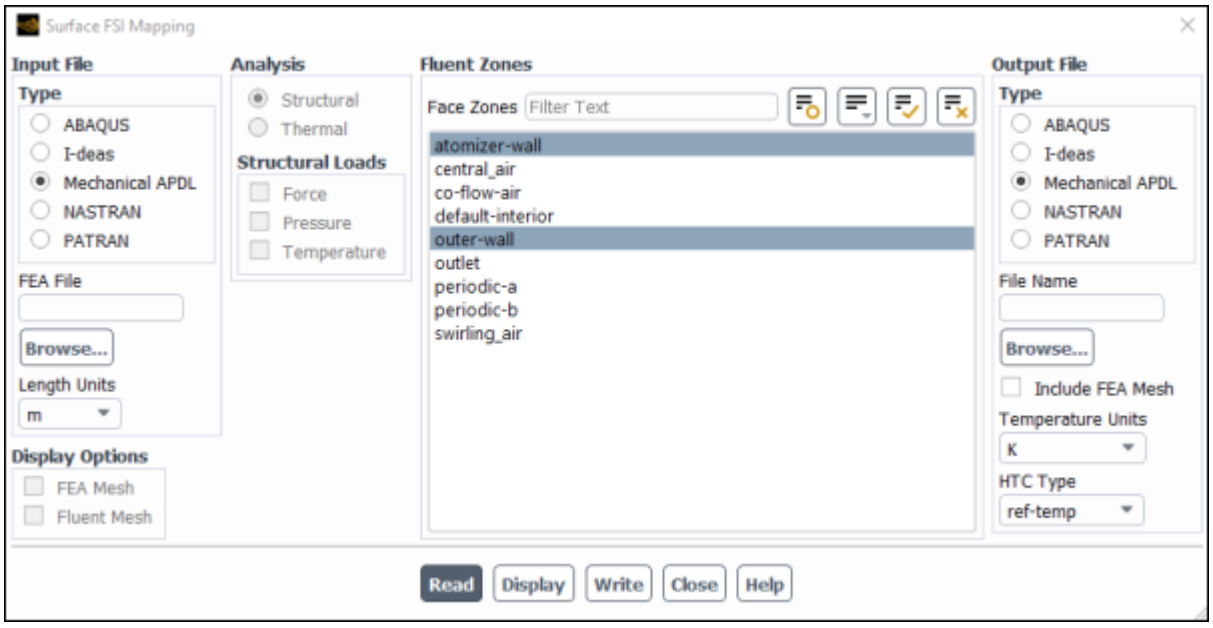
   File → FSI Mapping → Surface...

Figure 3.17: The Volume FSI Mapping Dialog Box for Cell Zone Data



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 3.18: The Surface FSI Mapping Dialog Box for Face Zone Data



2. Specify the parameters of the input file and read it into Ansys Fluent.

   a. Select the format of the input file from the **Type** list in the **Input File** group box, based on the FEA software with which it is associated. The choices include:

      - **ABAQUS**
      - **I-deas**
      - **Mechanical APDL**
      - **NASTRAN**
      - **PATRAN**

      For a list of the file extensions associated with these types, see the Input File column of Table 3.2: FEA File Extensions for FSI Mapping (p. 989).

   b. Enter the name and extension (along with the folder path, if it is not in the current folder) of the input file in the **FEA File** text-entry box. Alternatively, you can specify it through the **Select File** dialog box, which is opened by clicking the **Browse...** button.

   c. Specify the length units that were used in the creation of the input file by making a selection from the **Length Units** drop-down menu. This ensures that the input file is scaled appropriately relative to the Ansys Fluent file.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

d. Click the **Read** button to read the input file into memory.

Important:

Note that the input file will only be held in memory until the output file is written, or until the FSI mapping dialog box is closed.

3. Display the meshes so that you can visually verify that the input file is properly scaled and aligned with the Ansys Fluent mesh file.

   a. Make sure that the **FEA Mesh** and **Fluent - Mesh** options are selected in the **Display Options** group box. Note that you can disable either of these options if you want to examine one of the meshes independently.

   b. Click the **Display** button to display the meshes in the graphics window.

   Important:

   For the Ansys Fluent mesh, only the zones selected in the **Fluent Zones** group box will be displayed—in this case, the default selections. If the default zones are not appropriate, you should redisplay the meshes after you make your zone selections in a later step.

4. Specify the type of data variables to be mapped.

   a. Select either **Structural** or **Thermal** in the **Analysis** group box. Your selection should reflect the kind of further analysis you intend to pursue, and will determine what variables are available for mapping.

   b. Enable the variables you want to map in the **Structural Loads** or **Thermal Loads** group box. When mapping volume data, you can enable only **Temperature**. When mapping surface data, you can enable **Force**, **Pressure**, and **Temperature** for structural analysis, or **Temperature**, **Heat Flux**, and **Heat Trans Coeff** for thermal analysis.

   Important:

   Note that the **Energy Equation** must be enabled in the **Energy** dialog box if you want to map temperature for a structural analysis or any variable for a thermal analysis.

5. Select the zones that contain the data to be mapped in the **Fluent Zones** group box. You can select individual zones in the **Cell Zones** or **Face Zones** selection lists, or select all zones of a particular type in the **Zone Type** selection list. If you modify the default selections, you should display the meshes again, as described previously.

   Important:

   - Note that all wall zones in the **Face Zones** selection list are selected by default in the **Surface FSI Mapping** dialog box, and this includes the shadow walls created

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

for two-sided walls. If your Ansys Fluent file contains a wall/shadow pair (for example, separating a solid zone from a fluid zone), you should make sure that only the correct wall or shadow of the pair is selected.

- Inlet zones do not have heat transfer coefficient data, and so any attempts to map this combination will be ignored.

6. Specify the parameters of the output file and write it.

   a. Select the format of the output file from the **Type** list in the **Output File** group box, based on the software with which you plan to perform your finite element analysis. The choices in this list are the same as those for the input file type. Note that you can select an output file type that is different from the input file type.

      For details about the file extensions associated with the various types of output files, see the Output File column of Table 3.2: FEA File Extensions for FSI Mapping (p. 989).

   b. Enter the name (with the folder path, if appropriate) of the output file in the **File Name** text-entry box. Alternatively, you can specify it through the **Select File** dialog box, which is opened by clicking the **Browse...** button.

   c. To include additional FEA information like node/element information in the exported output file, enable **Include FEA Mesh**. By default, this option is disabled and therefore, only the selected boundary condition values are exported.

   d. When mapping temperature for a structural analysis or any variable for a thermal analysis, make a selection in the **Temperature Units** drop-down menu. Table 3.3: Units Associated with the Temperature Units Drop-Down List Selections (p. 993) shows the units for the mapped variables, depending on the **Temperature Units** selection.

      Table 3.3: Units Associated with the Temperature Units Drop-Down List Selections

Temperature Units Selection	Temperature	Heat Flux	Heat Transfer Coefficient
K	K	W/m^2	W/m^2-K
C	$^{\circ}C$	W/m^2	W/m^2- $^{\circ}C$
F	$^{\circ}F$	BTU/ft^2-hr	BTU/ft^2-hr- $^{\circ}F$

   e. When mapping the heat transfer coefficient for a thermal analysis, make a selection in the **HTC Type** drop-down menu to determine how the heat transfer coefficient h_{eff} is calculated.

      ref-temp

      calculates h_{eff} using Equation 41.50 (p. 4235), where T_{ref} is the reference temperature defined in the Reference Values Task Page (p. 5100). Note that this option has the same definition as the field variable **Surface Heat Transfer Coef.**, as described in Alphabetical Listing of Field Variables and Their Definitions (p. 4171).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

cell-temp

calculates h_{eff} using the general form of Equation 41.50 (p. 4235), but defines T_{ref} as the temperature of the cell adjacent to the face.

wall-func-htc

calculates h_{eff} using Equation 41.69 (p. 4247). Note that this option has the same definition as the field variable **Wall Func. Heat Tran. Coef.**, as described in Alphabetical Listing of Field Variables and Their Definitions (p. 4171).

f. Click **Write** to write an output file in which the Ansys Fluent data has been mapped to the mesh of the input file.

The input file will be released from memory when the output file is written.

3.23. Saving Picture Files

Graphic window displays can be saved in various 2D and 3D formats (see Choosing the Picture File Format (p. 996) for a full listing of the supported file types). There can be slight differences between pictures and the displayed graphics windows depending on your settings and hardware, as the pictures may be generated using the internal software renderer while the graphics windows may use specialized graphics hardware for optimum performance. To eliminate such differences and save these files at the fastest rate possible, you must follow all of the following best practices:

- Run Cortex on a suitable machine with an appropriate graphics card and the latest drivers (for details, see the Ansys website). Note that you can assign Cortex to a particular machine using the `-gui_machine=<hostname>` command line option, or by selecting **Specify Machine** from the **Graphics Display Machine** list in the **Scheduler** tab of Fluent Launcher.
- Ensure that Cortex / the host process is run on a separate machine than that used for compute node 0. For example, do not include the machine assigned using the `-gui_machine` option as the first machine in the hosts file / machine list (specified using the `-cnf=x` command line option).
- Do not set the graphics driver to `null`, `x11` (for Linux), or `msw` (for Windows).
- When saving picture files, enable the **Fast hardcopy** option in the **Preferences** dialog box (under **Graphics**).

Many systems provide a utility to "dump" the contents of a graphics window into a raster file. This is generally the fastest method of generating a picture (since the scene is already rendered in the graphics window), and guarantees that the picture is identical to the window.

Note:

You can control the line thickness in saved images by specifying the **Line width** setting in **Preferences**, under **Save Picture Settings**.

For additional information, see the following sections:

3.23.1. Using the Save Picture Dialog Box

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

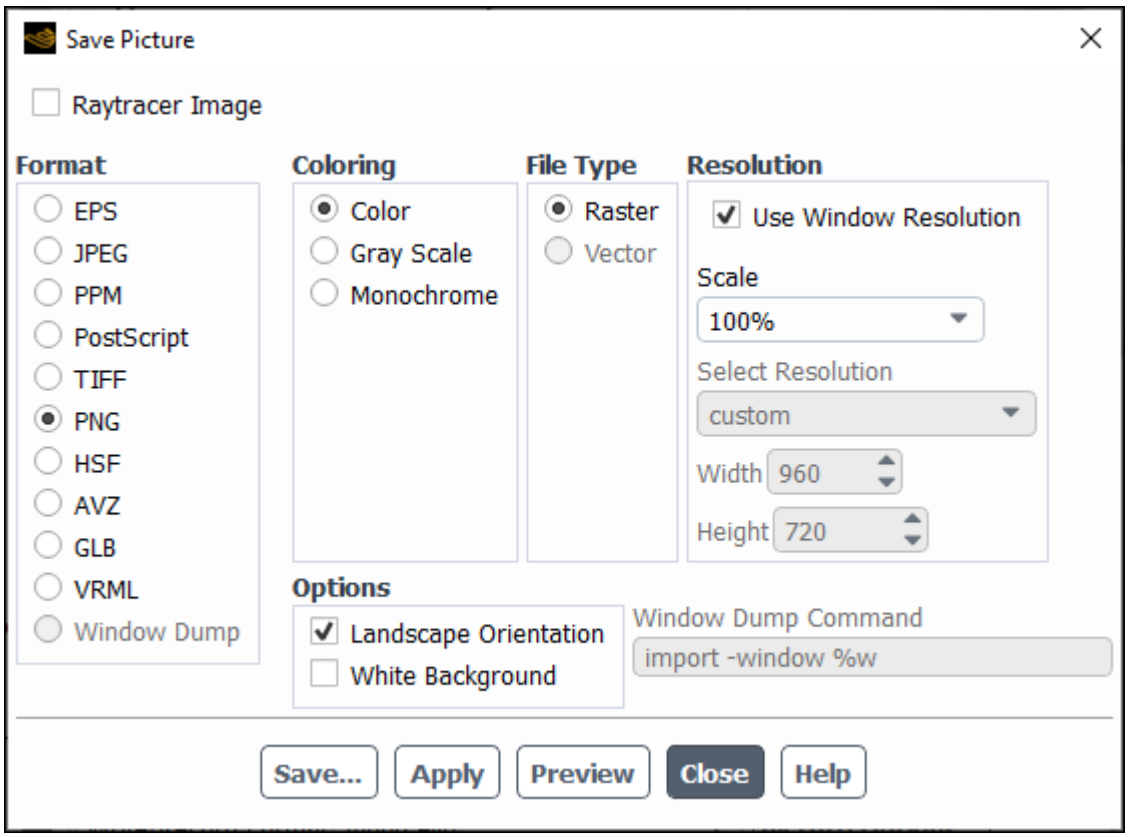
3.23.2. Picture Options for PostScript Files

3.23.1. Using the Save Picture Dialog Box

To set picture parameters and save picture files, use the Save Picture Dialog Box (p. 5200) (Figure 3.19: The Save Picture Dialog Box (p. 995)).

File → Save Picture...

Figure 3.19: The Save Picture Dialog Box



For your convenience, this dialog box may also be opened using the **Save Picture** button ( ) in the standard toolbar.

The procedure for saving a picture file is as follows:

1. (Optional) Enable **Raytracer Image** if you want a raytracer to render the image prior to saving. Refer to Realistic Rendering Using Raytracing (p. 3965) for additional information.
2. Choose the picture file **Format**.
3. Set the **Coloring**.
4. Specify the **File Type**, if applicable.
5. Define the **Resolution**, if applicable.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. Set the appropriate **Options**.
7. If you are generating a window dump, specify the **Window Dump Command**.
8. (optional) Preview the result by clicking **Preview**.

   Note:

   The preview for a **Monochrome** picture may not match the end result. If you see gray, it will be black when the picture is saved.

9. Click the **Save...** button and enter the file name in the resulting **Select File** dialog box. See Automatic Numbering of Files (p. 928) for information on special features related to file name specification.

If you are not ready to save a picture but want to save the current picture settings, click the **Apply** button instead of the **Save...** button. The applied settings become the defaults for subsequent pictures.

3.23.1.1. Choosing the Picture File Format

To choose the picture file format, select one of the following items in the **Format** list:

EPS

(Encapsulated PostScript) output is the same as PostScript output, with the addition of Adobe Document Structuring Conventions (v2) statements. Currently, no preview bitmap is included in EPS output. Often, programs that import EPS files use the preview bitmap to display on-screen, although the actual vector PostScript information is used for printing (on a PostScript device). You can save EPS files in raster or vector format.

JPEG

is a common raster file format.

PPM

output is a common raster file format.

PostScript

is a common vector file format. You can also choose to save a PostScript file in raster format.

TIFF

is a common raster file format.

PNG

is a common raster file format.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

HSF

is HOOPS Visualize Stream Format, a highly-compressible and streamable 2D/3D file format.

AVZ

is the free Ansys Viewer Format, which is a 3D file format allowing you to visualize, share, collaborate, and interactively manipulate the displayed object. For additional information on the Ansys Viewer, refer to Ansys Viewer User's Guide.

Note:

Graphics effects such as reflections and the ground plane grid are not exported to AVZ format. (211327)

Limitations for AVZ Export:

- Only mesh faces and edges (not nodes) can be displayed in the Ansys Viewer.
- Contour values may be displayed incorrectly in the Ansys Viewer, if the **Node Values** option was disabled when the `.avz` file was saved.
- Contour lines are not exported to AVZ format.
- Lighting effects and the brightness of the display may vary in AVZ when compared to the Fluent graphics windows.
- When the entire colormap represents a single value, the color on the surface(s) may display differently in the Ansys Viewer than it does when it is displayed in Ansys Fluent.
- Scenes containing multiple colormaps may show the colormaps overlapping when displayed in the Ansys Viewer. You can rearrange the colormaps by dragging and dropping them to different locations in the graphics window (top, bottom, right) in Ansys Fluent before saving in AVZ format to avoid this overlap issue.
- Colormap properties such as font type and size and number format are not retained when imported into the Ansys Viewer.
- The Ansys Viewer has a fixed size for pathline and particle track displays that may not match the exact settings of the pathline or particle track object when it was saved in `.avz` format in Ansys Fluent.
- 2D plots cannot be saved in `.avz` format, including report plots, residuals, and XY plots.
- Mesh included as part of a scene may appear black, if the transparency has been modified from **0**.
- Hovering over individual vectors will not display their values in the Ansys Viewer. This also applies for pathline displays with the **Style** set to either **line**, **point**, or **sphere**.
- The colormap type and precision displayed in the Ansys Viewer may not match how the colormap appeared when the `.avz` file was saved in Ansys Fluent.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Cylindrical/Spherical silhouettes (artificial edges rendered for surfaces characterized by roundness that do not have a 'sharp edge') are not properly preserved and displayed in the Ansys Viewer.
- Mesh displays that are colored by a material are not rendered properly in the Ansys Viewer.

GLB

is a 3D file format frequently used in virtual reality (VR) and augmented reality (AR) applications. The file size is relatively small as it is a binary format of the GL Transmission Format (glTF).

Note:

- You cannot save animation files in GLB format.
- You can only export and successfully view faces or faces + edges. Exporting only edges is not supported.

VRML

is a graphics interchange format that allows export of 3D geometrical entities that you can display in the Ansys Fluent graphics window. This format can commonly be used by VR systems and the 3D geometry can be viewed and manipulated in a web-browser graphics window.

Important:

Non-geometric entities such as text, titles, color bars, and orientation axis are not exported. In addition, most display or visibility characteristics set in Ansys Fluent, such as lighting, shading method, transparency, face and edge visibility, and the making of front faces transparent, are not explicitly exported but are controlled by the software used to view the VRML file.

Window Dump

(Linux systems only) selects a window dump operation for generating the picture. With this format, you must specify the appropriate **Window Dump Command**.

Important:

The advantage to saving the animation sequence using the **HSF File** option is that these files are highly compressible and can be viewed and interacted with using a “HOOPS Viewer” application on iOS and Android equipped devices. The “HOOPS Viewer” application can be downloaded to iOS and Android equipped devices from the “App Store” and “Google Play” respectively.

An advantage to saving the animation sequence using the **PPM Image** option is that you can use the separate pixmap image files for the creation of a single GIF file. GIF file creation can be done quickly with graphics tools provided by other third-party graphics packages such as ImageMagick, that is, `animate` or `convert`. For example, if you save the PPM files starting with the string `sequence-2`, and you are using the ImageMa-

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

gick software, you can use the `convert` command with the `-adjoin` option to create a single GIF file out of the sequence using the following command.

```
convert -adjoin sequence-2_00*.ppm sequence2.gif
```

3.23.1.2. Specifying the Color Mode

For all formats except VRML, HSF, and the window dump, specify the type of **Coloring** you want to use for the picture file.

- Select **Color** for a color-scale copy.
- Select **Gray Scale** for a gray-scale copy.
- Select **Monochrome** for a black-and-white copy.

Note:

The preview for a **Monochrome** picture may not match the end result. If you see gray, it will be black when the picture is saved.

Most monochrome PostScript devices render **Color** images in shades of gray, but to ensure that the color ramp is rendered as a linearly-increasing gray ramp, you should select **Gray Scale**.

3.23.1.3. Choosing the File Type

When you save an EPS (Encapsulated PostScript) or PostScript file, choose one of the following under **File Type**:

- A **Raster** file defines the color of each individual pixel in the image. Raster files have a fixed resolution. The supported raster formats are EPS, JPEG, PPM, PostScript, TIFF, and PNG.
- A **Vector** file defines the graphics image as a combination of geometric primitives like lines, polygons, and text. Vector files are usually scalable to any resolution. The supported vector formats include EPS, PostScript, and VRML.

Important:

For the quickest print time, you can save vector files for simple 2D displays and raster files for complicated scenes.

3.23.1.4. Defining the Resolution

For raster picture files (that is, JPEG, PPM, TIFF, and PNG), you can control the resolution of the picture image by specifying the size (in pixels). Set the desired **Width** and **Height** under **Resolution**. If the **Width** and **Height** are both zero, the picture is generated at the same resolution as the active graphics window. To check the size of the active window in pixels, click **Info** in the **Display Options** dialog box.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For EPS and PostScript files, specify the resolution in dots per inch (**DPI**) instead of setting the width and height.

3.23.1.5. Picture Options

For all picture formats except VRML, HSF, and the window dump, you can control two additional settings under **Options**:

- Specify the orientation of the picture using the **Landscape Orientation** button. If this option is turned on, the picture is made in landscape mode; otherwise, it is made in portrait mode.
- Control the foreground/background color using the **White Background** option. If this option is enabled, the picture is saved with a white background and, for 2D plots, the axes and labels are saved in black. This option allows for the production of consistent images, regardless of variations in user preferences, such as when running in Dark theme or with a custom background color.

3.23.2. Picture Options for PostScript Files

Ansys Fluent provides options that allow you to save PostScript files that can be printed more quickly. The following options are found in the `display/set/picture/driver/ post-format` text menu:

`fast-raster`

enables a raster file that may be larger than the standard raster file, but will print much more quickly.

`raster`

enables the standard raster file.

`rle-raster`

enables a run-length encoded raster file that is about the same size as the standard raster file, but will print slightly more quickly. This is the default file type.

`vector`

enables the standard vector file.

3.23.2.1. Window Dumps (Linux Systems Only)

If you select the **Window Dump** format, the program uses the specified **Window Dump Command** to save the picture file. For example, if you want to use `xwd` to capture a window, set the **Window Dump Command** to

```
xwd -id %w >
```

When the dump occurs, Ansys Fluent automatically interprets `%w` to be the ID number of the active window.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When you click the **Save...** button, the **Select File** dialog box appears. Enter the file name for the output from the window dump (for example, `myfile.xwd`).

If you are planning to make an animation, save the window dumps into numbered files, using the %n variable. To do this, use the **Window Dump Command** (`xwd -id %w`), but for the file name in the **Select File** dialog box enter `myfile%n.xwd`. Each time a new window dump is created, the value of %n increases by one. So there is no need to tack numbers onto the picture file names manually.

To use the **ImageMagick** animate program, saving the files in MIFF format (the native **ImageMagick** format) is more efficient. In such cases, use the **ImageMagick** tool `import`. Set the default **Window Dump Command** enter

```
import -window %w
```

Click **Save...** to open the **Select File** dialog box. Specify the output format to be MIFF by using the `.miff` suffix at the end of file name.

The window dump feature is both, system and graphics-driver specific. Thus the commands available for dumping windows depends on the particular configuration.

The window dump captures the window exactly as it is displayed, including resolution, colors, transparency, and so on. For this reason, all of the inputs that control these characteristics are disabled in the **Save Picture** dialog box when you enable the **Window Dump** format. If you are using an 8-bit graphics display, use one of the built-in raster drivers (for example, TIFF) to generate higher-quality 24-bit color output rather than dumping the 8-bit window.

3.23.2.2. Previewing the Picture Image

Before saving a picture file, you have the option of previewing what the saved image will look like. Click **Preview** to open a new window that will display the graphics using the current settings. This allows you to investigate the effects of different options interactively before saving the final, approved picture.

3.24. Setting Data File Quantities

If you have requested the writing of files in the legacy format (see Reading and Writing Files in the Legacy Format (p. 934)), the information saved in a data file by default includes a standard set of quantities that were computed during the calculation. These quantities are specifically suitable for postprocessing and restarting solutions in Ansys Fluent. If, however, you plan to postprocess the data file in an application other than Ansys Fluent (such as Ansys CFD-Post) you may want to include additional quantities that are derived from the standard quantities.

Note:

- If you plan to postprocess using EnSight, it is recommended that you export EnSight Case Gold Files (p. 967) or Common Fluids Format - Post Files (p. 966) instead of saving legacy data files with additional quantities.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

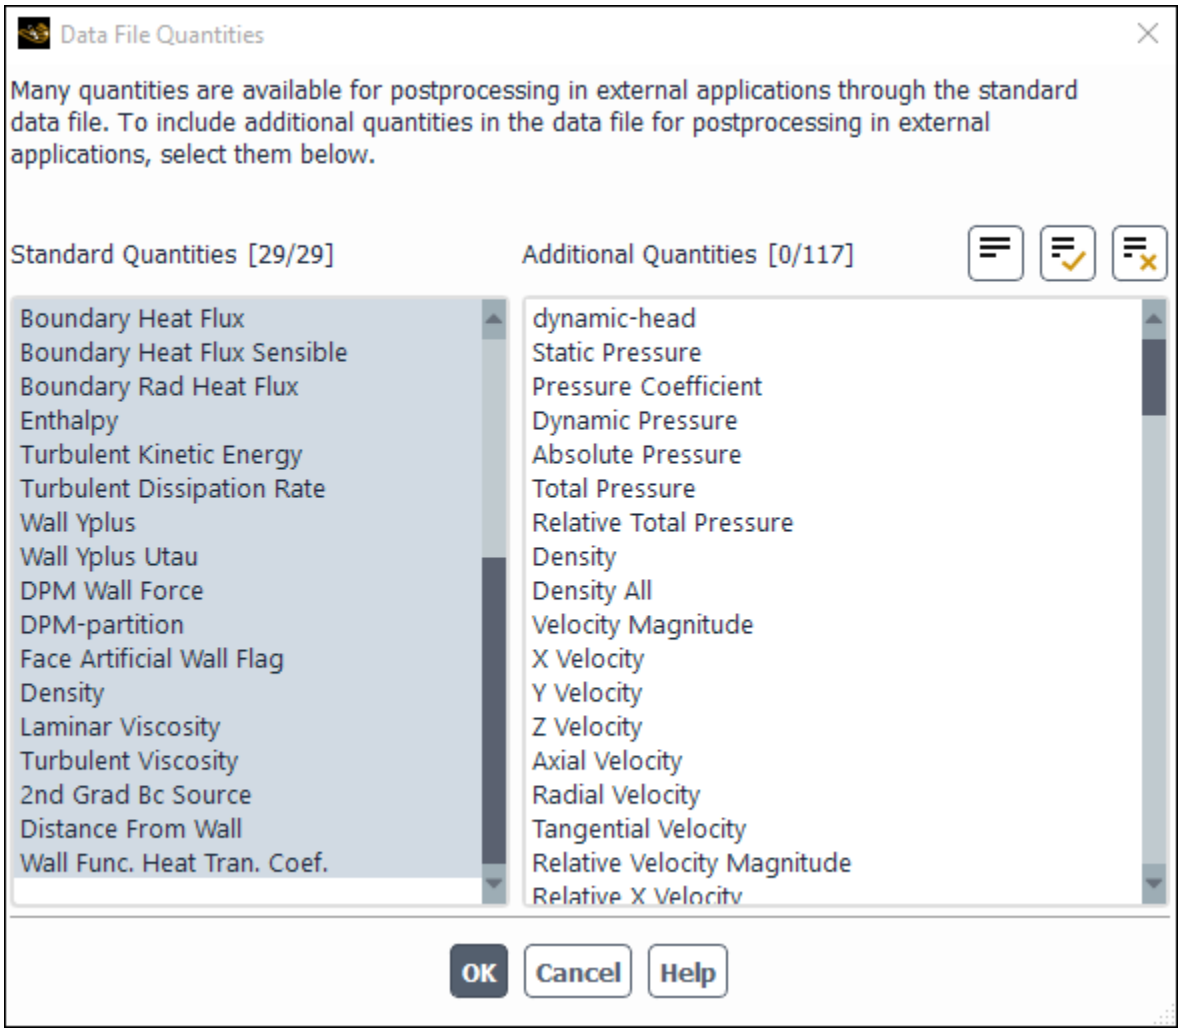
- If you plan to postprocess using Ansys CFD-Post, note that some standard quantities are also listed as additional quantities; where a standard quantity has a corresponding entry in the additional quantity list, the latter should be selected. This is because Ansys CFD-Post requires that some standard quantities are derived in a specific form.
- Not all standard quantities are available in CFD-Post for postprocessing. An example of such a quantity is Mach number.

The procedure for generating a legacy data file with additional quantities is as follows:

1. Read the case file for your simulation.
2. Initialize the solution using the Solution Initialization Task Page (p. 5125).
3. Specify the quantities to be written in the legacy data file, using the **Data File Quantities** dialog box (Figure 3.20: The Data File Quantities Dialog Box (p. 1002)).

   File → Data File Quantities...

Figure 3.20: The Data File Quantities Dialog Box



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

a. View the **Standard Quantities** list to see what will be saved in the data file by default. Note that you cannot deselect any of the **Standard Quantities**.

b. Select the additional quantities you want saved from the **Additional Quantities** selection list.

c. Click **OK**.

4. Save the legacy case file. Note that the legacy data file quantities specified in the previous step will be saved as part of the case file.

5. Run the calculation and save the legacy data file. This can be done as separate steps, or as one step if you have selected the automatic saving of data files via the Calculation Activities Task Page (p. 5134).

The **Data File Quantities** dialog box can also be opened by clicking the **Data File Quantities...** button in the **Autosave Case/Data** dialog box.

3.25. The .fluent File

When starting up, Ansys Fluent looks in your home folder for an optional file called `.fluent`. If it finds the file, it loads it with the Scheme `load` function. This file can contain Scheme functions that customize the code's operation.

The `.fluent` file can also contain TUI commands that are executed via the Scheme function `ti-menu-load-string`. For example, if the `.fluent` file contains

```
(ti-menu-load-string "file read-case test.cas.h5")
```

then Ansys Fluent will read in the case file `test.cas.h5`. For more details about the function `ti-menu-load-string`, see Text Menu Input from Character Strings.

Important:

Another optional file, `.tgrid`, if present, is also loaded at start up. This file may contain Scheme functions that customize the operation of the code in meshing mode. When both the `.fluent` and `.tgrid` files are present, the `.tgrid` file will be loaded first, followed by the `.fluent` file, when the solution mode is launched. Hence, the functions in the `.fluent` file will take precedence over those in the `.tgrid` file for the solution mode.

The `.fluent` file is not loaded automatically when switching to solution mode from meshing mode. You will need to load the file separately using the Scheme load function, if needed.

3.26. Coupled Simulations in Ansys Fluent with Functional Mock-up Unit (FMU) Files

Ansys Fluent can run co-simulations with Functional Mock-up Unit (FMU) files using the Functional Mock-up Interface technology (FMI). For more information about the FMI standard, see http://fmi-standard.org/. Co-simulation type FMU contains the model and the solver. When FMU is coupled to

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ansys Fluent, the two simulation participants run independently and only exchange data. Ansys Fluent supports both the import and the use of FMU files.

Note:

There are two types of FMU in general: co-simulation and model exchange. Ansys Fluent only supports co-simulation FMU.

The following limitations exist when co-simulation type FMU in Ansys Fluent:

- Only co-simulation type FMU using FMI 2.0 is supported.
- Co-simulations with FMU are available only with the pressure-based solver.
- Only one FMU file can be imported into Ansys Fluent.
- A simulation with FMU can be restarted only if the FMU file supports restarting. (For information on how to determine whether restarts are supported, see this document).
- For co-simulations with FMU files that support restarting, only case files that have been saved in the default format (***.h5**) can be restarted.

To import an FMU file and set up a coupled simulation in Ansys Fluent:

1. Read a case or mesh file into Ansys Fluent.
2. Select the **File/Import/FMU...** menu to import an FMU file.
3. In the **Import FMU File** dialog box, click **Import...**.
4. In the **Select File** dialog box that opens, select the FMU file (`*.fmu`) to be imported. Once you click **OK**, the FMU file is imported into Ansys Fluent.

   During the import process, Ansys Fluent automatically recognizes the FMU output variables, creates corresponding input parameters, and links them to the FMU output parameters. If the imported FMU does not support restarts, a warning message will be displayed.

   Once the import operation is complete, the **Import FMU File** dialog box displays the following Fluent parameters and FMU variables (see Figure 3.21:**Import FMU File** Dialog Box (p. 1005)):

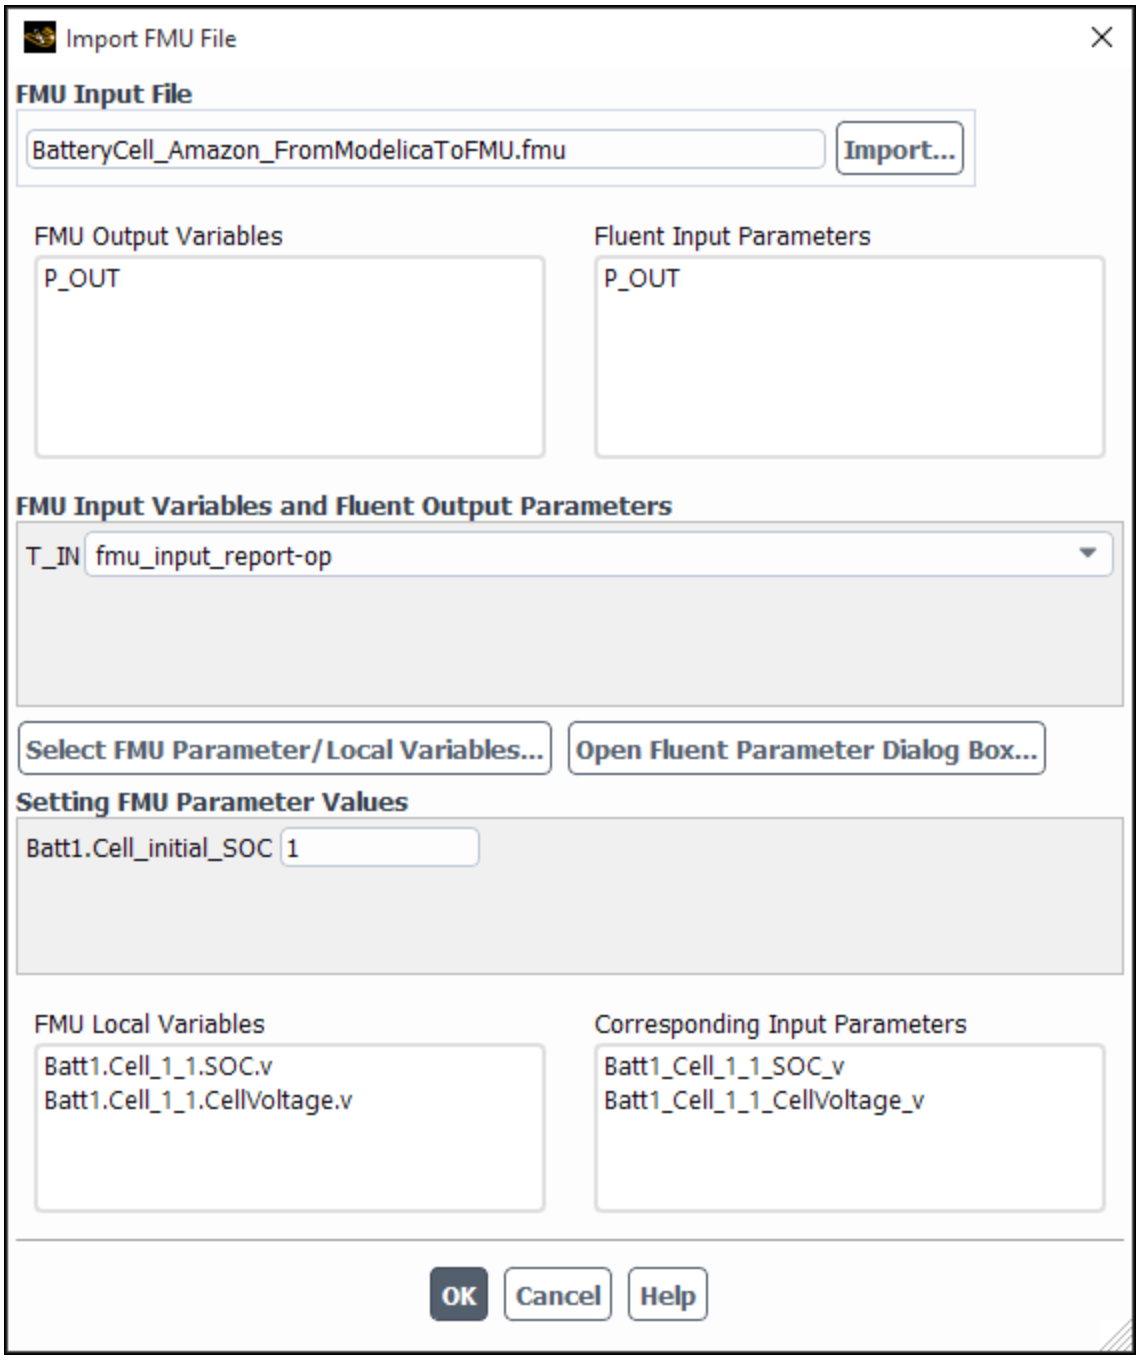
   - FMU output variables and the corresponding Fluent input parameters.

     Fluent input parameters are generated automatically and always have the same names as FMU output variables. The **FMU Output Variables** and **Fluent Input Parameters** lists are for information only. You do not need to do anything else.

   - FMU input variables and Fluent output parameters that have been defined in your simulation. All output parameters that have been defined in Ansys Fluent appear in the drop-down lists next to the FMU input variables.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 3.21: Import FMU File Dialog Box



5. For each FMU input variable, select an appropriate Fluent output parameter from the corresponding drop-down list.

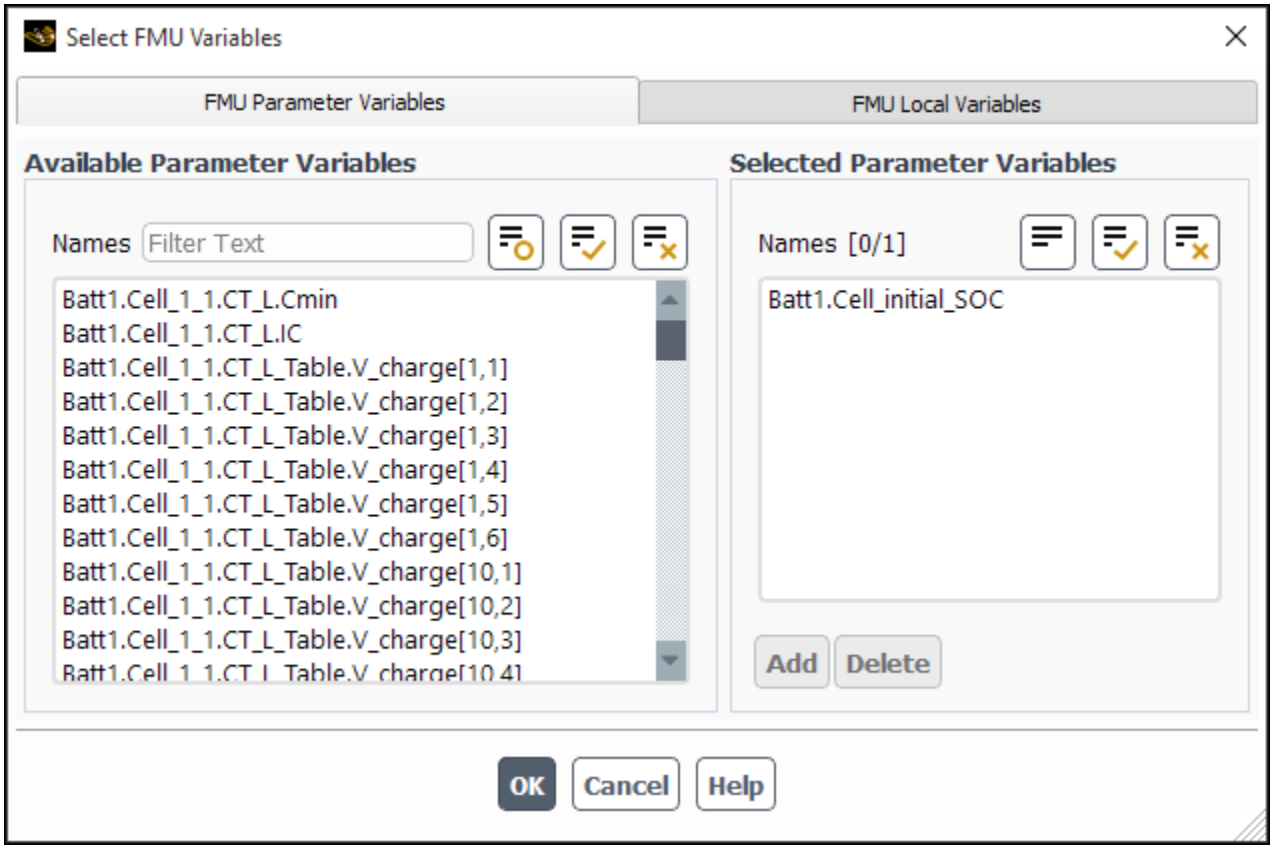
   Right after the FMU file has been imported, FMU input variables are not yet defined. You must hook them to the Fluent output parameters. If Fluent output parameters are not yet defined in your case, you can define them as described in Creating Output Parameters (p. 4099), and then revisit the **Import FMU File** dialog box and complete this step later on.

6. (optional) If you want to modify values of one or more FMU parameter variables, select them in the **Select FMU Variables** dialog box as follows:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

a. Click the **Select FMU Parameters and Local Variables** button.

Figure 3.22: Import FMU File Dialog Box



b. In the **FMU Parameter Variables** tab, use the **Add** and **Delete** buttons to modify a list of the FMU parameter variables:

- To add a parameter variable to the **Selected Parameter Variables** list, select it in the **Available Parameter Variables** multiple-selection list variables (use **Ctrl** or **Shift** to select multiple variables) and click **Add**.
- To delete a parameter variable from the **Selected Parameter Variables** list and move it back to the **Available Parameter Variables** multiple-selection list, select it and click **Delete**.

c. Click **OK** to close the **Select FMU Variables** dialog box.

The selected FMU parameter variables and the corresponding data entry boxes will appear under **Setting FMU Parameters Values** in the **Import FMU File** dialog box.

d. Adjust the values of the FMU parameters as desired.

Note:

- If you want to conduct parametric studies with different combinations of FMU parameters to evaluate their effects on the model behavior, you need to revisit the **Import FMU File** dialog box and edit the FMU parameter settings as appropriate for each run.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- To review the input and output parameters defined in your case, click the **Open Fluent Parameter Dialog Box** button.

7. (optional) Select the FMU local variables you want to monitor using the **Select FMU Variables** dialog box in a manner similar to that for selecting FMU parameter variables:

   a. Click the **Select FMU Parameters and Local Variables** button.

   b. In the **FMU Local Variables** tab, use the **Add** and **Delete** buttons to modify a list of the FMU local variables.

   c. Click **OK** to close the **Select FMU Variables** dialog box.

      The selected parameters are listed in the **FMU Local Variables** list. Ansys Fluent automatically creates corresponding input parameters with matching names and displays them in the **Corresponding Input Parameters** list. You can then use the Ansys Fluent reporting functionality to create report definitions for these parameters (see Expression Report Definition Dialog Box (p. 5413) for details).

8. Click **OK** to close the **Import FMU File** dialog box.

   Ansys Fluent links the FMU input variables and the selected Fluent output parameters and establishes the data exchange connection between FMU and Fluent. The newly created input parameters will appear in the tree under **Parameters & Customization/Parameters/Input Parameters** branch and in the **Parameters** dialog box.

9. Use the new Fluent input parameters that are linked to the FMU output variables in the usual way.

   For example, if the FMU output variable is a heat source term, you can hook this source term to proper cell zones in the energy equation. (Note that the units of the input parameter and the quantity for which you want to use it must be consistent. In case of inconsistent units, you can easily create additional input parameters to either scale the units or to use the input parameter in an expression. See Fluent Expressions Language (p. 1013) for more details about using expressions.)

10. Initialize your solution. During the solution initialization, Ansys Fluent creates an instance of FMU and initializes it.

11. Run the calculation.

    During the calculation, FMU is called at the first iteration in an unsteady simulation or every iteration in a steady simulation.

To run your simulation from an existing case file that has already imported FMU.

1. Load the case file. Make sure that the FMU file is in the same folder as the case file or saved in the absolute path you specified when setting up the case.

2. If FMU does not support restarts, re-initialize the solution and run the calculation from beginning.

3. If FMU supports restarts, load the data file and continue the simulation.

Chapter 4: Unit Systems

This chapter describes the units used in Ansys Fluent and how you can control them. Information is organized into the following sections:

4.1. Restrictions on Units

4.2. Units in Mesh Files

4.3. Built-In Unit Systems in Ansys Fluent

4.4. Customizing Units

Ansys Fluent enables you to work in any unit system, including inconsistent units. Thus, for example, you may work in British units with heat input in Watts or you may work in SI units with length defined in inches. This is accomplished by providing Ansys Fluent with a correct set of conversion factors between the units you want to use and the standard SI unit system that is used internally by the solver. Ansys Fluent uses these conversion factors for input and output, internally storing all parameters and performing all calculations in SI units. Both solvers always prompt you for the units required for all dimensional inputs.

Units can be altered part-way through a problem setup and/or after you have completed your calculation. If you have entered some parameters in SI units and then you switch to British, all of your previous inputs (and the default prompts) are converted to the new unit system. If you have completed a simulation in SI units but you would like to report the results in any other units, you can alter the unit system and Ansys Fluent will convert all of the problem data to the new unit system when results are displayed. As noted above, all problem inputs and results are stored in SI units internally. This means that the parameters stored in the case and data files are in SI units. Ansys Fluent simply converts these values to your unit system at the interface level.

4.1. Restrictions on Units

It is important to note that the units for some inputs in Ansys Fluent are different from the units used for the rest of the problem setup.

- You must always define the following in SI units, regardless of the unit system you are using:
  - Boundary profiles (see Profiles (p. 1540))
  - Source terms (see Defining Mass, Momentum, Energy, and Other Sources (p. 1360))
  - Custom field functions (see Custom Field Functions (p. 4251))
  - Data in externally-created XY plot files (see Creating an XY Plot From Multiple Data Sources (Including Files) (p. 4031))
  - User-defined functions (See the Fluent Customization Manual for details about user-defined functions.)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- If you define a material property by specifying a temperature-dependent polynomial or piecewise-polynomial function, remember that temperature in the function is always in units of Kelvin or Rankine. If you are using Celsius or Kelvin as your temperature unit, then polynomial coefficient values must be entered in terms of Kelvin; if you are using Fahrenheit or Rankine as the temperature unit, values must be entered in terms of Rankine. See Defining Properties Using Temperature-Dependent Functions (p. 1590) for information about temperature-dependent material properties.

4.2. Units in Mesh Files

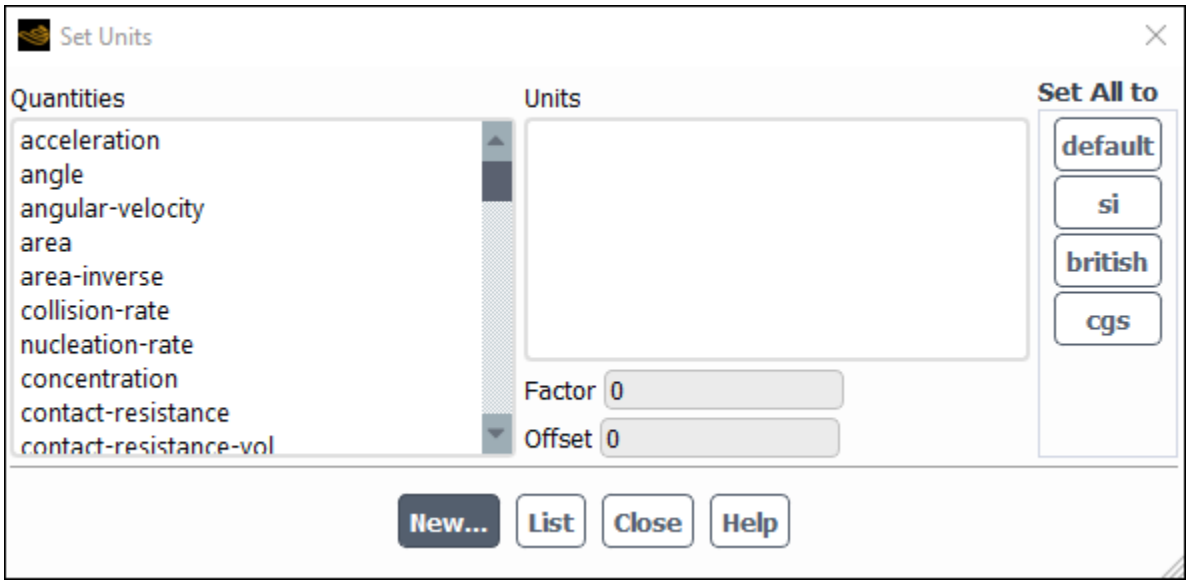
Some mesh generators allow you to define a set of units for the mesh dimensions. However, when you read the mesh into Ansys Fluent, it is always assumed that the unit of length is meters. If this is not true, you must scale the mesh, as described in Scaling the Mesh (p. 1262).

4.3. Built-In Unit Systems in Ansys Fluent

Ansys Fluent provides four built-in unit systems: British, SI, CGS, and "default", all of which can be selected in the **Set Units** dialog box (Figure 4.1: The Set Units Dialog Box (p. 1010)), using the buttons under the **Set All to** heading. To display the **Set Units** dialog box, right-click **General** and click **Units...**, under **Setup** in the tree.

Setup → General → Units

Figure 4.1: The Set Units Dialog Box



To choose the English Engineering standard for all units, click the **british** button; to select the International System of units (SI) standard for all units, click the **si** button; to choose the CGS (centimeter-gram-second) standard for all units, click the **cgs** button; and to return to the "default" system, click the **default** button. The default system of units is similar to the SI system, but uses degrees instead of radians for angles. Clicking on one of the buttons under **Set All to** will immediately change the unit system. You can then close the dialog box if you are not interested in customizing any units.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Changing the unit system in the **Set Units** dialog box causes all future inputs that have units to be based on the newly selected unit system.

4.4. Customizing Units

If you would like a mixed unit system, or any unit system different from the four supplied by Ansys Fluent (and described in Built-In Unit Systems in Ansys Fluent (p. 1010)), you can use the **Set Units** dialog box (Figure 4.1: The Set Units Dialog Box (p. 1010)) to select an available unit or specify your own unit name and conversion factor for each quantity.

For additional information, see the following sections:

4.4.1. Listing Current Units

4.4.2. Changing the Units for a Quantity

4.4.3. Defining a New Unit

4.4.1. Listing Current Units

Before customizing units for one or more quantities, you may want to list the current units. You can do this by clicking the **List** button at the bottom of the **Set Units** dialog box. Ansys Fluent will print out a list (in the text window) containing all quantities and their current units, conversion factors, and offsets.

4.4.2. Changing the Units for a Quantity

Ansys Fluent will enable you to modify the units for individual quantities. This is useful for problems in which you want to use one of the built-in unit systems, but you want to change the units for one quantity (or for a few). For example, you may want to use SI units for your problem, but the dimensions of the geometry are given in inches. You can select the SI unit system, and then change the unit of length from meters to inches.

To change the units for a particular quantity, you will follow these two steps:

1. Select the quantity in the **Quantities** list (they are arranged in alphabetical order).

2. Choose a new unit from those that are available in the **Units** list.

For the example cited above, you would choose **length** in the **Quantities** list, and then select **in** in the **Units** list. The **Factor** will automatically be updated to show 0.0254 meters/inch. (See Figure 4.1: The Set Units Dialog Box (p. 1010).) If there was a nonzero offset for the new unit, the **Offset** field would also be updated. For example, if you were using SI units but wanted to define temperature in Celsius instead of Kelvin, you would select **temperature** in the **Quantities** list and **c** in the **Units** list. The **Factor** would change to 1, and the **Offset** would change to 273.15. Once you have selected the quantity and the new unit, no further action is needed, unless you want to change the units for another quantity by following the same procedure.

4.4.3. Defining a New Unit

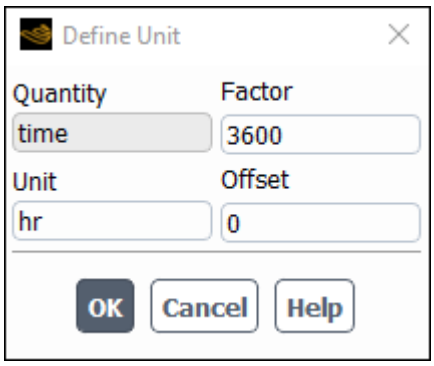
To create a new unit to be used for a particular quantity, you will follow the procedure below:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. In the **Set Units** dialog box, select the quantity in the **Quantities** list.

2. Click the **New...** button and the **Define Unit** dialog box (Figure 4.2: The Define Unit Dialog Box (p. 1012)) will open. In this dialog box, the selected quantity will be shown in the **Quantity** field.

   Figure 4.2: The Define Unit Dialog Box



3. Enter the name of your new unit in the **Unit** field, the conversion factor in the **Factor** field, and the offset in the **Offset** field.

4. Click **OK** in the **Define Unit** dialog box, and the new unit will appear in the **Set Units** dialog box.

For example, if you want to use hours as the unit of time, select **time** in the **Quantities** list in the **Set Units** dialog box and click the **New...** button. In the resulting **Define Unit** dialog box, enter `hr` for the **Unit** and `3600` for the **Factor**, as in Figure 4.2: The Define Unit Dialog Box (p. 1012). Then click **OK**. The new unit **hr** will appear in the **Units** list in the **Set Units** dialog box, and it will be selected.

4.4.3.1. Determining the Conversion Factor

The conversion factor you specify (**Factor** in the **Define Unit** dialog box) tells Ansys Fluent the number to multiply by to obtain the SI unit value from your customized unit value. Thus the conversion factor should have the form SI units/custom units. For example, if you want the unit of length to be inches, you should enter a conversion factor of 0.0254 meters/inch. If you want the unit of velocity to be feet/min, you can determine the conversion factor by using the following equation:

$$x\frac{\text{ft}}{\text{min}} \times \frac{0.3048\text{m}}{\text{ft}} \times \frac{\text{min}}{60\text{s}} = y\frac{\text{m}}{\text{s}} \tag{4.1}$$

You should enter a conversion factor of 0.0051, which is equal to 0.3048/60.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Chapter 5: Fluent Expressions Language

5.1. Introduction to Expressions

The Fluent Expression Language is an interpreted, declarative language based on Python, that enables you to:

- Specify complex boundary conditions and source terms with respect to time, iteration number, position, and solution variables.
- Specify various model and solver settings in terms of time or iteration.

Important:

Expression values are updated at the same frequency as the **Profile Update Interval** (specified in the **Run Calculation** task page).

5.1.1. Expression Syntax

An expression is a string representing a combination of values, variables, operators, and function calls that returns a value when evaluated with appropriate values for the variables.

For example: `Vmax*(5.0*exp(-t-0.3 [s]/2.8 [s]))`

The following sections cover the basic elements of proper expression syntax:

5.1.1.1. Expression Data Types

5.1.1.2. Expression Values

5.1.1.3. Expression Operations and Functions

5.1.1.1. Expression Data Types

The evaluated result of an expression can be a real number, a boolean, a real field or a boolean field. For example, `2*StaticPressure` evaluates to a real field when computed on a zone. Whereas, `average(2*StaticPressure, ["inlet"])` evaluates to a single real values.

Note:

Cell registers evaluate as boolean.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5.1.1.2. Expression Values

Values can be real numbers (for example, `1.0e-3`), integers (for example, -10, 5, 37), booleans (true or false), or quantities. Quantities are real numbers with units associated. The syntax supported for quantities is `<number> [ <unit> ]`, for example, `2324.0 [Pa kg^-3 s]`. The unit specification is based on CFX (Units Syntax in the *CFX-Pre User's Guide*).

5.1.1.3. Expression Operations and Functions

All of the following mathematical functions take inputs in the form of an expression that evaluates to a real number or a real field and return a real number or real field:

Table 5.1: Operations and Functions

Description	Function
Operators	+, -, *, /, ** (power), ^ (power), >, >=, <, <=, ==, !=

Conditional	`AND(<expr>, <expr>, …)`
	`IF(<cond>, <true_value>, <false_value>)`
	`NOT(<expr>)`
	`OR(<expr>, <expr>, …)`
	`XOR(<expr>)`

Flux	`FilmHeatTransferRate(['location', …],phase = <phase>)`
	`FilmMassFlowRate(['location', …],phase = <phase>)`
	`HeatTransferRate(['location', …],phase = <phase>)`
	`MassFlow(['location', …],phase = <phase>)`
	`RadiationHeatTransferRate(['location', …],phase = <phase>)`
	`SensibleHeatTransferRate(['location', …],phase = <phase>)`

Hyperbolic	`acosh(<expr>)`
	`asinh(<expr>)`
	`atanh(<expr>)`
	`cosh(<expr>)`
	`sinh(<expr>)`
	`tanh(<expr>)`

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Description	Function

Mathematical	`abs(<expr>)`
	`*besselJ(n**, <expr>)`
	`*besselY(n**, <expr>)`
	`ceil(<expr>)`
	`exp(<expr>)`
	`floor(<expr>)`
	`gradient(<expr>)`
	`log(<expr>)`
	`log10(<expr>)`
	`max(<expr>, <expr>, …)`
	`min(<expr>,<expr>, …)`
	`mod(<expr>, <expr>)`
	`normalize(<expr>,['location',…])`
	`round(<expr>)`
	`sqrt(<expr>)`
	`step(<expr>)`
	`trunc(<expr>)`
	*`besselJ` is a Bessel function of the first kind and `besselY` is a Bessel function of the second kind.
	**n must be a constant of type 'double'.

Reduction	`Area(['location', 'location', …])`
	`AreaAve(Field, ['location'])`
	`AreaInt(Field, ['location'])`
	`*Average(<expr>, ['location', 'location', …], Weight= <None| 'Area'| 'Volume'| 'Mass'| 'MassFlowRate'| 'AbsMassFlowRate'>)`
	`Centroid(['location'])`
	`Count(['location'])`
	`CountIf(Boolean_Expr, ['location'])`

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Description	Function
	Force (['location'], …) MassAve(Field,['location']) MassFlowAve(Field, ['location']) MassFlowAveAbs(Field, ['location']) MassFlowInt(Field, ['inelt1'], ['inlet2']) MassInt(Field, ['location']) Maximum(<expr>, ['location', 'location', …]) Minimum(<expr>, ['location', 'location', …]) Moment(<point>, ['location']) PressureForce(['location'], …) *Sum(<expr>, ['location', 'location', …], Weight= <None| 'Area'| 'Volume'| 'Mass'| 'MassFlowRate'| 'AbsMassFlowRate'>) SumIf(Field, Boolean_Expr, ['location'], Weight=[Weight]) ViscousForce([<location>, <location>, …]) Volume([<location>, <location>, …]) VolumeAve(Field, ['location']) VolumeInt(Field, ['location'])
Trigonometric	acos(<expr>) asin(<expr>) atan(<expr>) atan2(<expr>, <expr>) cos(<expr>) sin(<expr>) tan(<expr>)
Vector	cross(<expr>, <expr>) dot <vector1>, <vector2>)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Description	Function

	`unitVector(<x>, <y>, <z>)`
	
	`<vector>.dir`
	
	`vector(<x>, <y>, <z>, ["unit"])`

*For mass-weighted reduction operations (`Sum` and `Average`), weight. `MassFlowRate` is equivalent to a mass-weighted surface integral (`Sum`) or surface average (`Average`), `AbsMassFlowRate` is equivalent to the absolute value mass-weighted surface integral (`Sum`) or surface average (`Average`) , and `Mass` is equal to a mass-weighted volume integral.

Operations

Components of vectors can be accessed with the `.x`, `.y`, and the `.z` suffixes; magnitude can be accessed with the `.mag` suffix.

Important:

Do not use multiple comparison operators within a single expression, as the operation will not work as intended. For example, `300[K]< StaticTemperature < 400[K]` will not work. To accomplish this expression, use `AND(StaticTemperature>300[K], StaticTemperature<400[K])`.

IF Statements

The `IF(<cond>, <true_value>, <false_value>)` function returns the `<true_value>` if `<cond>` is true, else it returns the `<false_value>`. Any of the arguments can be fields. The type and unit dimension of `<true_value>` and `<false_value>` must be the same.

OR Statements

`OR(<cond1>, <cond2>)` returns true if any of the conditions (any of which can be a boolean field) returns true.

AND Statements

`AND(<cond1>, <cond2>)` returns true if all of the conditions (any of which can be a boolean field) returns true.

Flux Operations

The following flux operations are explained in greater detail:

- **FilmHeatTransferRate([<location>, ...],phase = <phase>)**—compute the heat transfer rate of the film at the specified location for the specified phase. *Note that you do not need to provide a phase for single-phase flow.*
- **FilmMassFlowRate([<location>, ...],phase = <phase>)**—compute the mass flow rate of the film at the specified location for the specified phase. *Note that you do not need to provide a phase for single-phase flow.*

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **HeatTransferRate([<location>, ...],phase = <phase>)**—compute the heat transfer rate at the specified location for the specified phase. *Note that you do not need to provide a phase for single-phase flow.*
- **MassFlow([<location>, ...],phase = <phase>)**—compute the mass flow rate at the specified location for the specified phase. *Note that you do not need to provide a phase for single-phase flow.*
- **RadiationHeatTransferRate([<location>, ...],phase = <phase>)**—compute the radiation heat transfer rate at the specified location for the specified phase. *Note that you do not need to provide a phase for single-phase flow.*
- **SensibleHeatTransferRate([<location>, ...],phase = <phase>)**—compute the sensible heat transfer rate at the specified location for the specified phase. *Note that you do not need to provide a phase for single-phase flow.*

Important:

Fluxes are evaluated on boundaries and face zones, but not on user-defined post-processing surfaces (such as planes and iso-surfaces). *This input requirement is similar to flux reports.*

Mathematical Operations

The following mathematical operations are explained in greater detail:

- **gradient(<expr>)**—compute the spatial gradient of an expression. For example: `Average(gradient(StaticPressure).mag,['wall-top','wall-bottom'])`.

  The **gradient()** function computes the gradient of the expression using the currently selected gradient method (see Choosing the Spatial Discretization Scheme (p. 3561) for additional information). In some cases, the values obtained may not match the solver gradients for the same variable, as special techniques are employed when computing solver gradients to improve solver robustness. These techniques are not applied when computing the gradients of expressions.

- **normalize(<expr>, [<location>,...])**—normalize the value of an expression by scaling according to the maximum value of the expression at the specified location(s), which is equivalent to: `(<expr> - Minimum(<expr>, [<location>]))/(Maximum(<expr>, [<locations>]) - Minimum(<expr>, [<location>]))`.

- **Step (<expr>)**

  Step functions work as follows (`x` must be a non-dimensional expression of type real):

  If `step(x)` < `0.0` return `0.0`

  If `step(x)` == `0.0` return `0.5`

  If `step(x)` > `0.0` return `1.0`

Reduction Operations

The following reduction operations provide simpler access to more complex operations:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **AreaAve(Field, ['location'])**—calculates the area averaged value for the specified field variable and location. This reduction operation is equivalent to `Average(Field, ['location'], Weight='Area')`.
- **AreaInt(Field, ['location'])**—calculates the area integrated averaged value for the specified field variable and location. This reduction operation is equivalent to `Average(Field, ['location', Weight], Weight='Area')`.
- **Centroid(['location'])**—calculates the geometric centroid of the specified location(s) as a vector.
- **Count(['location'])**—calculates the number of *solve* cells included in the specified location. This reduction operation is equivalent to `Sum(1, ['location'])`.
- **CountIf(Boolean_Expr, ['location'])**—calculates the number of *solve* cells in the specified location according to the provided boolean expression. This reduction operation is equivalent to Sum(IF(Boolean_Expr, 1, 0),['location']).
- **Force(['location'])**—calculates the force on the location(s) specified (should be walls) as a vector. *The expression may include porous walls*.
- **MassAve(Field,['location'])**—calculates the mass-weighted average value for the specified field variable and location. This reduction operation is equivalent to `Average(Field, ['location'], Weight='Mass')`.
- **MassFlowAve(Field, ['location'])**—calculates the mass-flow-weighted average value for the specified field variable and location. This reduction operation is equivalent to `Average(Field, ['location'], Weight='MassFlowRate')`.
- **MassFlowAveAbs(Field, ['location'])**—calculates the absolute value of the mass-flow-weighted average for the specified field variable and location. This reduction operation is equivalent to `Average(Field, ['location'], Weight='AbsMassFlowRate')`.
- **MassFlowInt(Field, ['inelt1'], ['inlet2'])**—calculates the total mass flow across the specified inlets. This reduction operation is equivalent to `Sum(Field, ['inlet1', 'inlet2'], Weight='MassFlowRate')`.
- **MassInt(Field, ['location'])**—computes the total mass-weighted value for the specified field and location. This reduction operation is equivalent to `Sum(Field, ['location'], Weight='Mass')`.
- **Maximum(Field, ['location'])**—computes maximum value for the specified field and location.
- **Minimum(Field, ['location'])**—computes minimum value for the specified field and location.
- **Moment([[<PointExpression>], 'location'])**—calculates the moment vector about the specified point (which can be single-valued expression) for the given location(s).
- **PressureForce(['location'])**—calculates the pressure force on the location(s) specified (should be walls) as a vector.
- **Sum(Field, ['location'], Weight=[Weight])**—computes the sum of the specified field variable at the specified location.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **SumIf(Field, Boolean_Expr, ['location'], Weight=[Weight])**—computes the sum of the specified field variable at the specified location according to the provided boolean operation. This reduction operation is equivalent to `Sum(IF(Boolean_Expr, Field, 0), ['location'], Weight=[Weight])`.
- **ViscousForce(['location'])**—calculates the viscous force on the location(s) specified (should be walls) as a vector.
- **VolumeAve(Field, ['location'])**—calculates the volume-weighted average value for the specified field variable and location. This reduction operation is equivalent to `Average(Field, ['location'], Weight='Volume')`.
- **VolumeInt(Field, ['location'])**—calculates the volume-weighted total for the specified value and location. This reduction operation is equivalent to `Sum(Field, ['location'], Weight='Volume')`.

Vector Operations

- **cross(<expr>, location)**—compute the cross product of an expression and a location. For example: `cross(Force(['wall-top', 'wall-bottom']),Centroid(['wall-top', 'wall-bottom'])).mag`.
- **dot(<v1>, <v2>)**—calculates the dot product of vectors.
- **<v>.dir**—calculates a unit vector along the direction of <v>, which is equivalent to <v>/<v>.mag.
- **vector (<Xexpression>, <Yexpression>, <Zexpression>)**—calculates a vector from scalar component expressions. The components should evaluate to the same units, but they can be a mix of field and single-valued vector expressions. For example, `vector(-y, x, 0[m])`.
- **vector (<X>, <Y>, <Z>, <unit>)**—calculates a vector in the specified units from constant values. For example, `vector(0.4, 0.5, 0.2,'cm')`.
- **unitVector (<X>, <Y>, <Z>)**—calculates a unit vector from constant values.

5.1.2. Units Validation

Expressions are validated to ensure they have consistent unit types. For example, Fluent flags `1 [cm] + TotalPressure` because centimeters are not units of pressure. Note that units can still be provided in different unit systems, for example, `1 [atm] + 200 [Pa]`.

Important:

Consider using absolute units when specifying temperature (either Kelvin or Rankine). *If an expression contains multiple instances of a temperature expressed in Celsius or Fahrenheit, Fluent will convert each value separately into absolute units, which could lead to unexpected results.*

5.2. Expression Sources

Expression sources are the variables that can be used in expressions.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5.2.1. Field Variables
5.2.2. Solution Variables
5.2.3. Scientific Constants
5.2.4. Aliases
5.2.5. Profiles

5.2.1. Field Variables

A subset of the Fluent postprocessing field variables are available for use in expressions. See Appendix: Supported Field Variables (p. 1052) for a listing of all the available field variables.

Note:

Some variables require additional context, which is specified in the following format: `Variable(<context>="<context value>")`. For example, to get the species mass fraction of carbon dioxide: `MassFraction(species="co2")`.

In multiphase simulations, the phase context must be specified. For example: `MassFraction(species="co2", phase="air")`.

The context for variables requiring it is provided in the **Variables (type/context)** column of Appendix: Supported Field Variables (p. 1052).

5.2.2. Solution Variables

The following solution variables are available:

Table 5.2: Solution Variables

Variable	Description
`Time`	Current time* *In steady state, time evaluates as 0, unless the case was run in transient, then switched to steady state, in which case it will evaluate as the latest time from the transient run.
`Timestep`	Current time step number* *In steady state, timestep evaluates as 0, unless the case was run in transient, then switched to steady

Variable	Description
	state, in which case it will evaluate as the latest timestep from the transient run.
DeltaTime	Current time step size* *In steady state, delta time evaluates as 0, unless the case was run in transient, then switched to steady state, in which case it will evaluate as the latest delta time from the transient run.
Iteration	Global iteration count

5.2.3. Scientific Constants

Table 5.3: Scientific Constants

Variable	Description	Value
PI	Pi	3.14159265358979323846
e	e (base of the natural logarithm)	2.71828182845904523536
R	Gas constant	8.314472 [J K^-1 mol^-1]
avogadro	Avogadro's number	6.02214199e23 [mol^-1]
boltzmann	Boltzmann constant	1.3806503 [J K^-1]
clight	Light velocity	2.99792458e8 [m s^-1]
echarge	Electron charge	1.60217653e-19 [A s]
g	Acceleration due to gravity	9.8066502 [m s^-2]
planck	Planck's constant	6.62606876e-34 [J s]
stephan	Stephan-Boltzmann constant	5.670400e-08 [W m^-2 K^-2]
mupermo	Magnetic permeability	4.0*PI*1.0e-7 [N A^-2]
epspermo	Electric constant	1./(clight*clight*mupermo)

5.2.4. Aliases

Aliases provide simplified syntax to access frequently used variables.

Table 5.4: Variable Aliases

Alias	Variable
x	Position.x
y	Position.y

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Alias	Variable
z	Position.z
u	Velocity.x
v	Velocity.y
w	Velocity.z
t	Time* *In steady state, time evaluates as 0, unless the case was run in transient, then switched to steady state, in which case it will evaluate as the latest time from the transient run.
dt	DeltaTime* *In steady state, delta time evaluates as 0, unless the case was run in transient, then switched to steady state, in which case it will evaluate as the latest delta time from the transient run.
iter	Global iteration count
T	StaticTemperature
P	StaticPressure
mf	MassFraction
Amag	FaceAreaMagnitude
vol	CellVolume
mass	CellVolume*Density

5.2.5. Profiles

You can use profiles in expressions to specify boundary and cell zone conditions, for postprocessing, and in reduction operations. Profiles are tabular data that can be imported into Fluent, which typically contain X, Y, and Z columns (for spatial profiles) or Time (for transient profiles), in addition to one or more dependent variable columns.

Prior to using profiles in an expression you must load one or more profiles. Refer to Reading and Writing Profile Files (p. 940) for additional information.

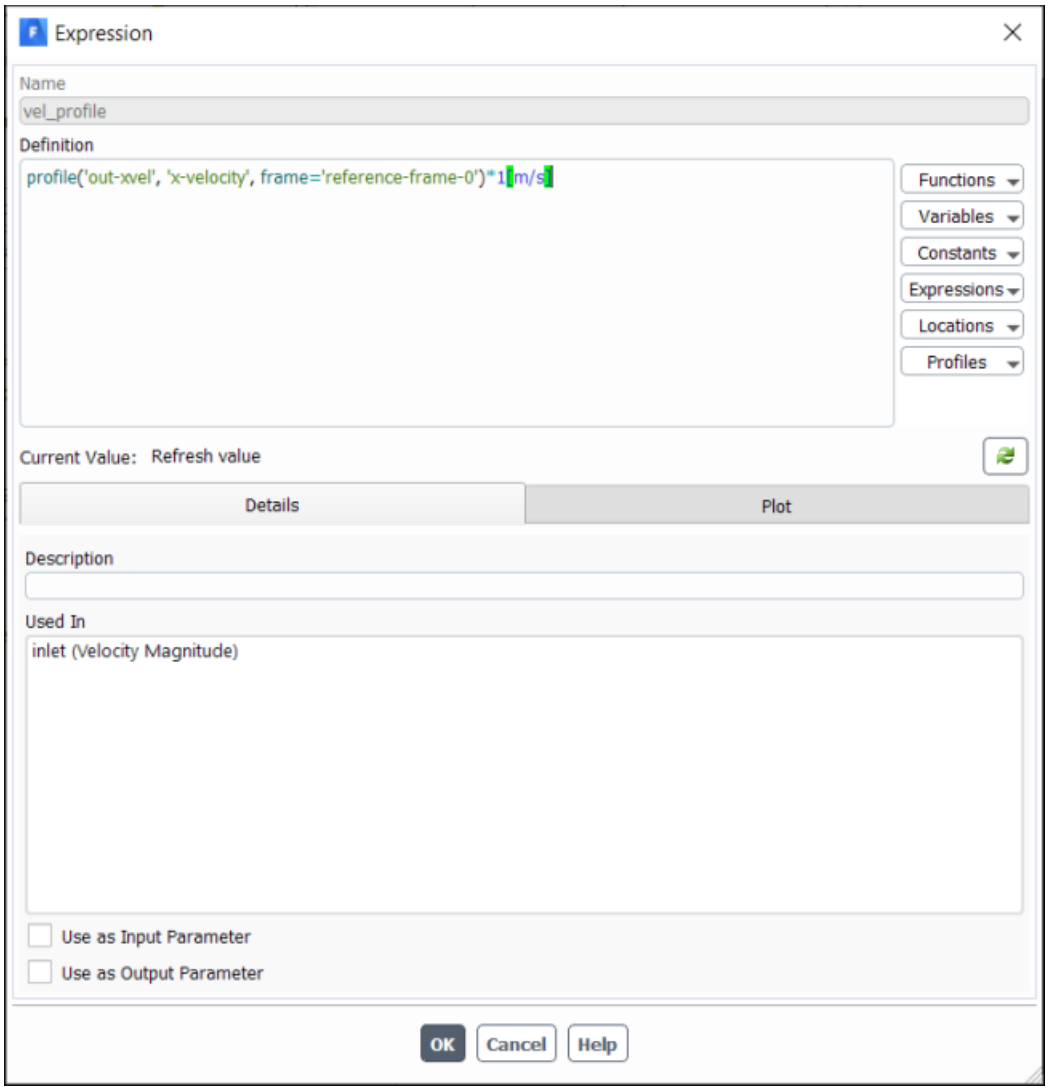
The profile expression requires the following inputs: **profile('<profile-name>', '<field-name>', frame='<reference-frame-name>')** (the reference frame argument is only for spatial profiles). Note

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

that if specified, profile coordinates are assumed to be of the specified frame and are therefore transformed to global coordinates prior to interpolation (profile coordinates are not transformed if you specify the reference frame as **frame='global'**).

Once the profile expression is defined, you can select it for the desired boundary condition or cell zone condition field. Refer to Expressions for Cell Zones and Boundary Conditions (p. 1025)

Figure 5.1: Example Profile Expression



5.3. Creating and Using Expressions

There are two ways that you can create expressions in Ansys Fluent. The first way is by creating an expression directly in the field where it will be applied. The second is by creating a named expression, which can be reused at multiple locations. These two formats are discussed in the following sections:

5.3.1. Directly Applied Expressions

5.3.2. Named Expressions

5.3.3. Context Specification

5.3.4. Plotting Expressions

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5.3.5. Postprocessing Expressions
5.3.6. Expression Manager

Important:

- Be careful to avoid situations where you are creating a circular dependency for a field or property. For example, setting the **Velocity Magnitude** field of a velocity inlet to `Velocity.mag`, without specifying a value for the velocity magnitude elsewhere, results in a 0-value for the velocity magnitude.
- 2D axisymmetric cases—expressions report quantities such as **Area**, on the actual cells/faces or on a per radian basis. Therefore, these quantities must be multiplied by 2π to get the value for the whole domain.

Note:

For postprocessing, expressions are evaluated using an algorithm that is suitable for a wide range of computations. First cell values are evaluated, then node values are interpolated from the cell values. Custom field functions (Custom Field Functions (p. 4251)) interpolate cell values to nodes prior to performing the computations of the provided definition. The observable difference in these two approaches appears in cases where there are steep gradients in cell values.

Depending on the specific expression, you may notice small differences in postprocessing for node-based variables (such as mesh or structures-based variables) if comparing expression results with directly evaluated postprocessing of the same variables. For example, if you compare a contour plot of **Total Mesh Displacement** with a contour plot of an expression evaluating total mesh displacement, you may see minute differences due to small approximation errors.

5.3.1. Directly Applied Expressions

You can use expressions at boundary and cell zone conditions, at certain material properties, and at fields and properties where profiles and parameters can also be defined. Expressions can also be used at most other non-cell zone or boundary condition locations where parameters can be defined.

The following sections deal with defining expressions directly:

5.3.1.1. Expressions for Cell Zones and Boundary Conditions
5.3.1.2. Expressions for Material Properties
5.3.1.3. Expressions in the Console

5.3.1.1. Expressions for Cell Zones and Boundary Conditions

To define an expression for a boundary or cell zone condition:

1. Open the dialog box for the boundary/cell zone where you want to create an expression. *For example, the* **Velocity Inlet** *dialog box.*

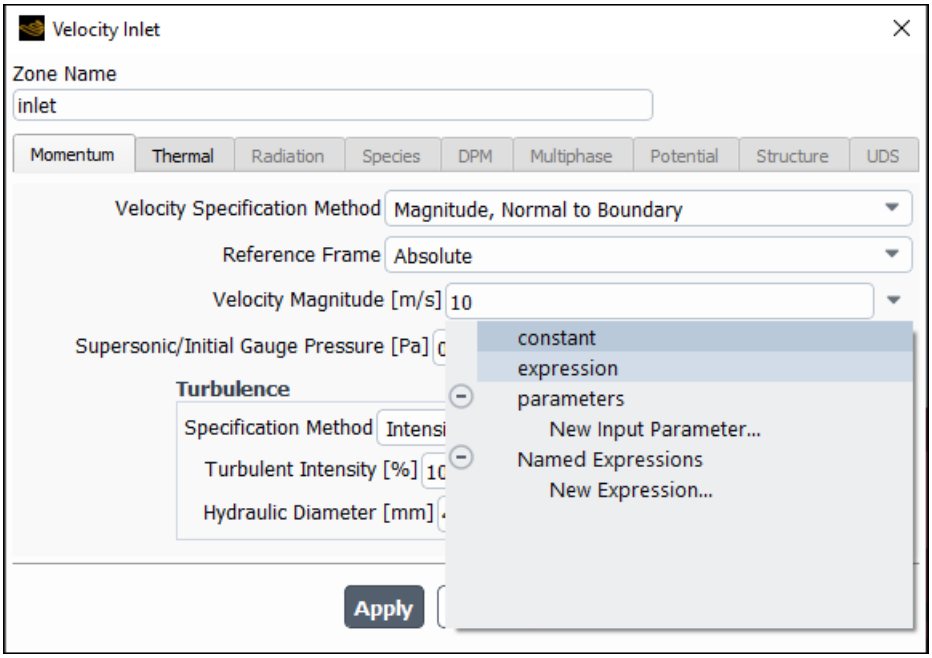
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Click the drop-down arrow to the right of the field that you would like to define using an expression and select **expression**.

Note:

Alternatively, you can:

- Create a new named expression (Named Expressions (p. 1029)).
- Select a valid expression from the list.

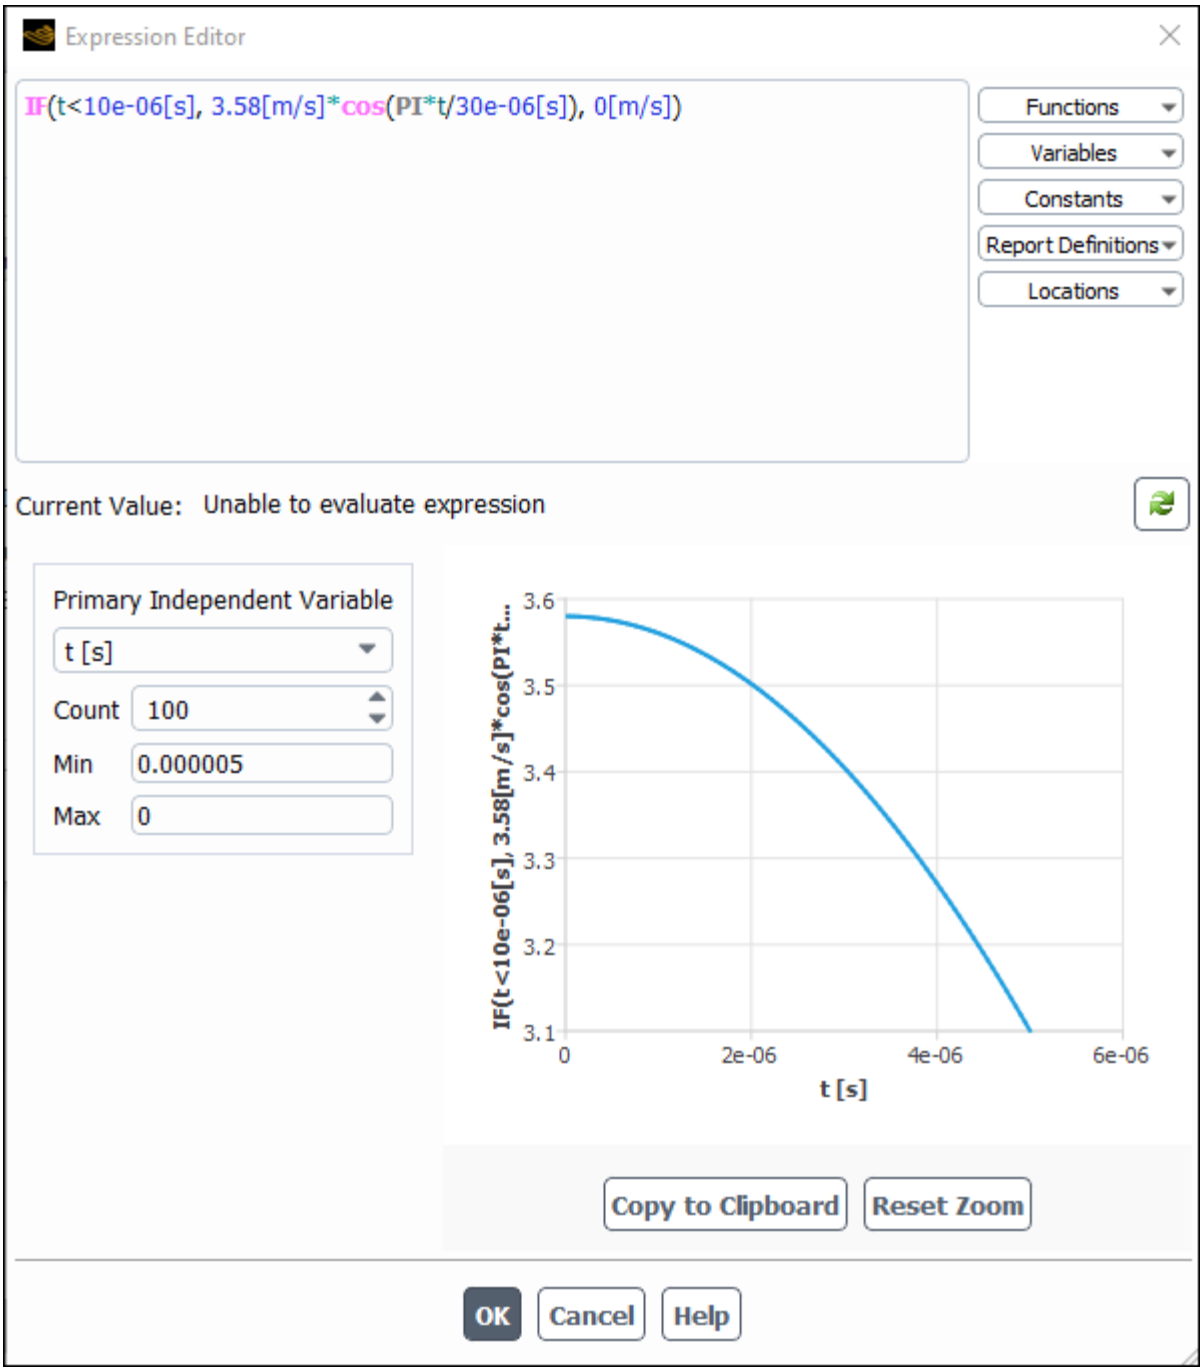


3. You can enter your expression directly in the text field. *Ansys Fluent provides messaging regarding the validity of the expression as soon as you begin entering it.*

Alternatively, you can click $f_{(x)}$ to open a bigger editor (Figure 5.2: The Expression Editor Dialog Box (p. 1027)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 5.2: The Expression Editor Dialog Box



Important:

Expressions allow for implicit locations. For example, you could specify the mass flux at a mass-flow-inlet boundary as `1 [kg/s]/Area()`. However, if you explicitly provide a location, that will be used (for example, `1 [kg/s]/Area(['outlet'])`.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5.3.1.2. Expressions for Material Properties

You can use expressions to define the following material properties:

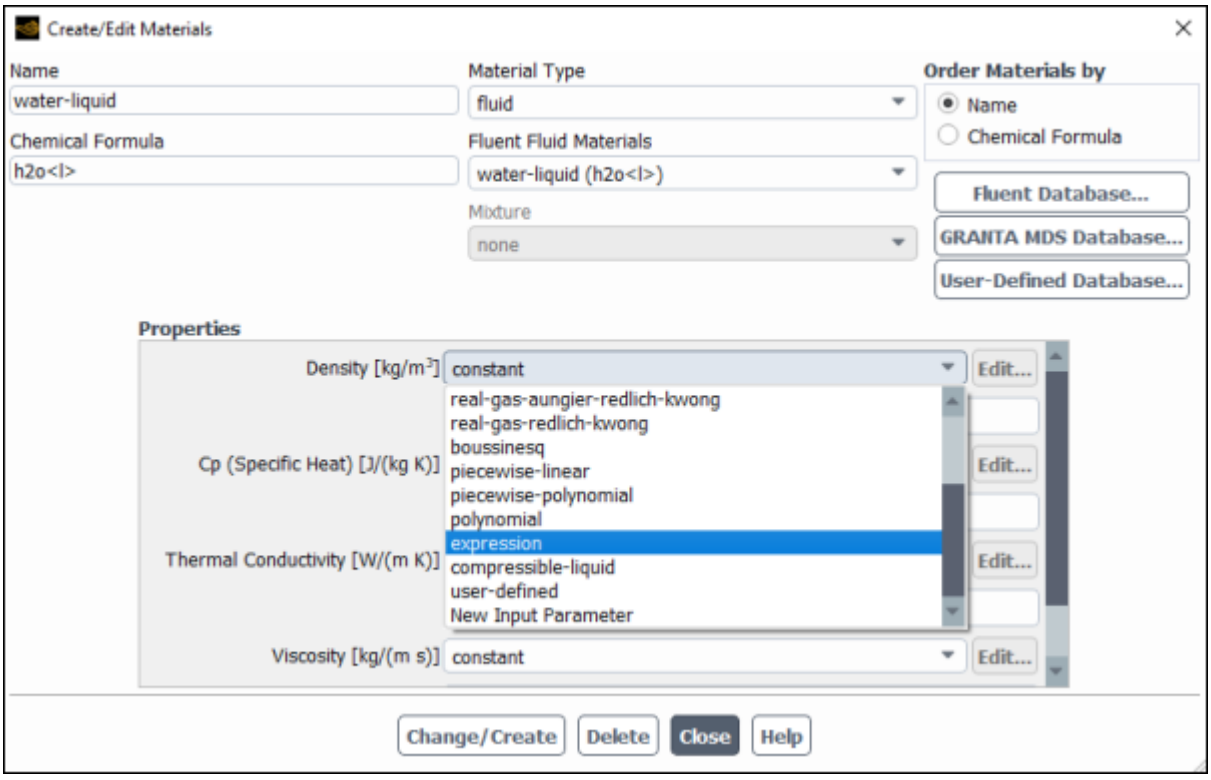
- Density
- Viscosity
- Thermal conductivity
- Absorption coefficient
- Scattering coefficient
- Lithium diffusivity
- Partition coefficient
- UDS diffusivities

To define an expression for a material property:

1. Open the **Create/Edit Materials** dialog box.

   Setup → **Materials** → **Fluid | Solid** → **<material name>** **Edit...**

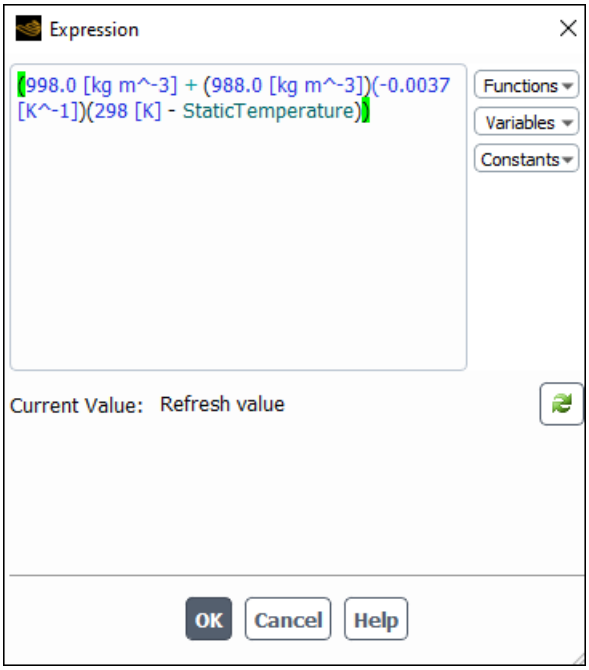
2. Click the drop-down arrow to the right of the property field that you would like to define using an expression and select **expression**.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Enter the expression in the **Expression** editor dialog box that opens.

Figure 5.3: Example Expression for Water Density



You can use the **Functions**, **Variables**, **Constants**, and **Expressions** drop-down lists when creating your expression. These lists contain the valid expression inputs.

Note:

Density can be a function of static temperature or absolute pressure, but not both. Density specification as a function of absolute pressure is primarily for modeling mild compressibility, such as compressible liquids. If density is specified as a function of absolute pressure, Fluent will automatically compute the speed of sound.

---

4. Click **OK** to save the expression.

5.3.1.3. Expressions in the Console

You can specify expressions for settings through the text user interface (Console). To do so, enter a string instead of a real value to specify a setting as an expression. *For example:*

```
/define/operating-conditions> operating-pressure
operating pressure (atm) [0] "1[atm]*sin(t/0.1[s])"
```

5.3.2. Named Expressions

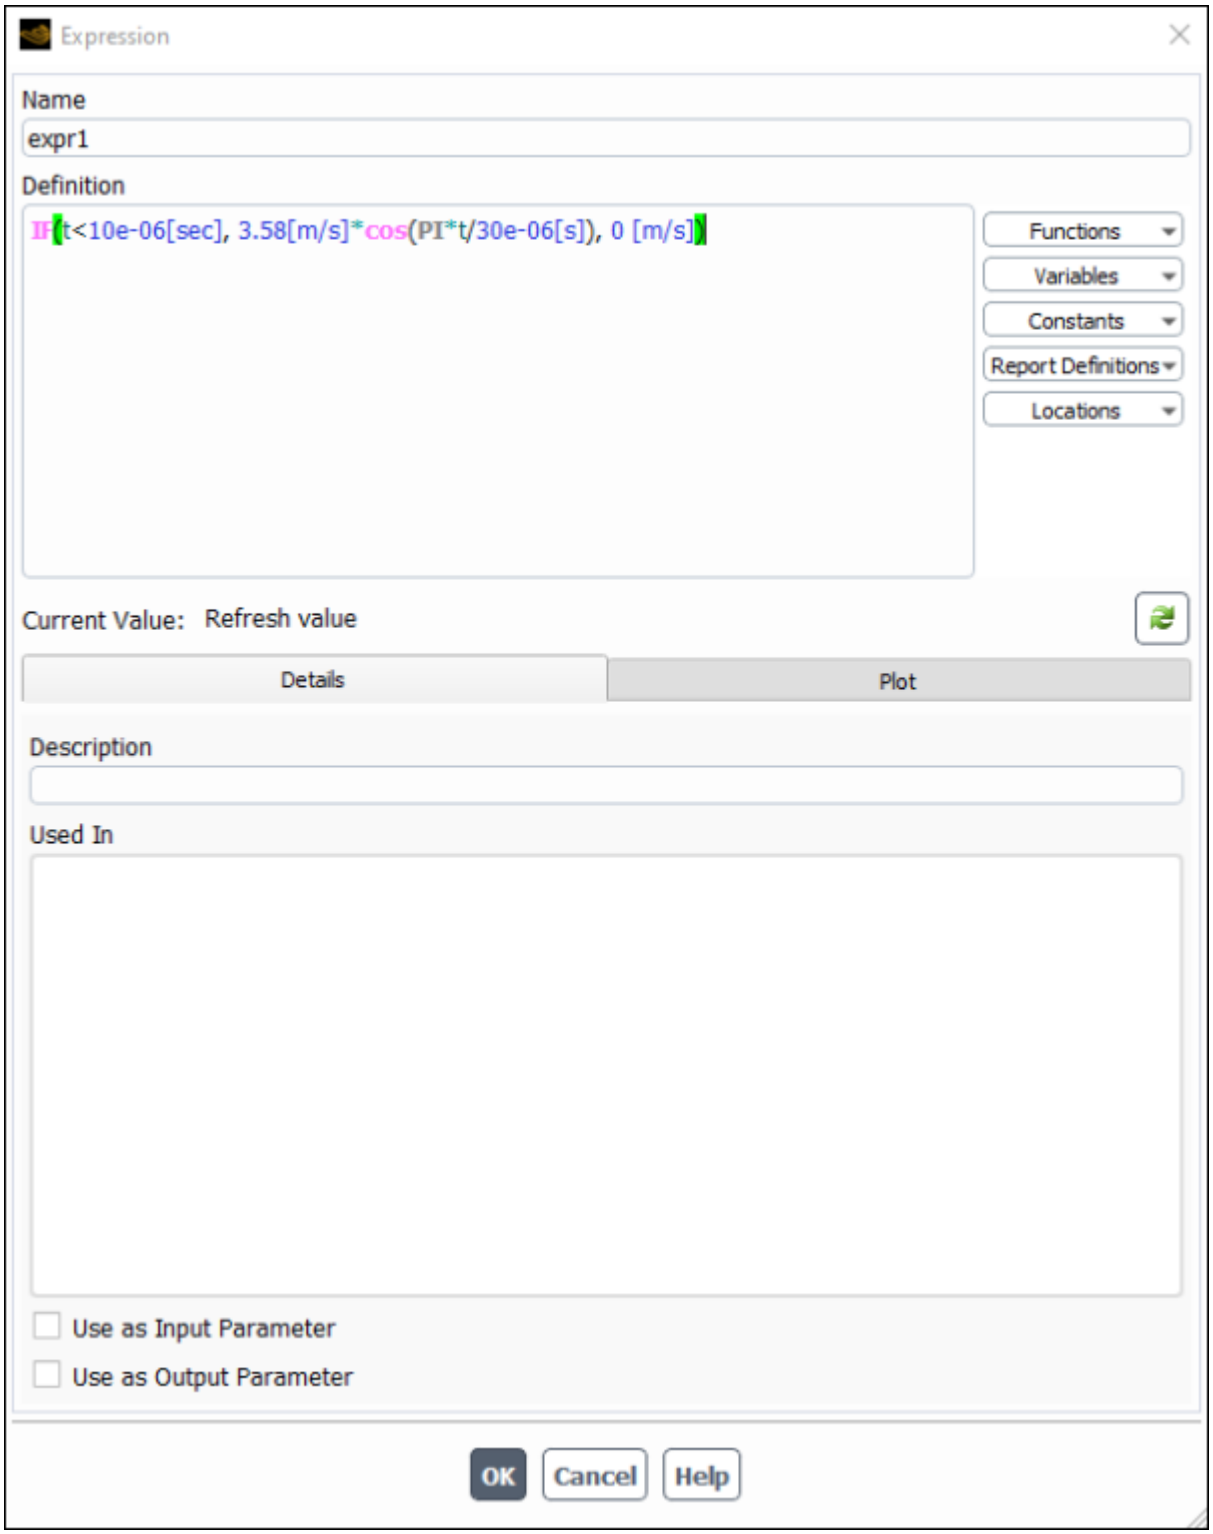
You can create, edit, and delete named expressions through the graphical user interface (GUI) via the right-click context menu in the Outline View tree. *Right-click options are also available for importing/exporting expressions from/to a file, computing expressions, marking them as input/output parameters, and printing expression details to the console.*

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can also managed named expression using the **Expression Manager** (Expression Manager (p. 1037)).

Setup → Named Expressions New...

Figure 5.4: The Expression Dialog Box



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Provide a **Name** for the expression. *The name must start with a letter and it may contain numbers and underscores.*

   Note:

   It may cause confusion if you create named expressions with names that match expression functions such as "exp" and "abs".

2. Enter the **Definition** of the expression. *You can use the drop-downs to the right of the* **Definition** *text box to add functions, variables, cell registers, constants, existing expressions, report definitions, locations, and profiles to this expression definition.*

   All of the variables supported by the Fluent Expression Language are listed in the drop-down list.

   Note:

   - When you use curly brackets "{}" to specify the name of a defined object, such as a report definition or cell register, automatic suggestions are disabled and you must provide the display name of that object.
   - The instantaneous value of a report definition is always used when a report definition is included in an expression.

3. (Optional) Add a **Description** of the expression.

4. (Optional) Enable **Use as Input Parameter**, if you want to use the named expression as an input parameter. Refer to Defining and Viewing Parameters (p. 1287) for additional information on parameters.

   Note:

   Only constant-value expressions can be marked as input parameters.

5. (Optional) Enable **Use as Output Parameter**, if you want to use the named expression as an output parameter. Refer to Creating Output Parameters (p. 4099) and Working With Input and Output Parameters in Workbench in the *Fluent in Workbench User's Guide* for additional information on parameters.

6. (Optional) Click to refresh the **Current Value** field to display the current value of the expression.

   Note:

   This feature is only available for expressions that evaluate to a single value, for example `Average(StaticPressure, ["inlet_1"])`, and not for expressions that evaluate as a field, such as `2*AbsolutePressure`.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

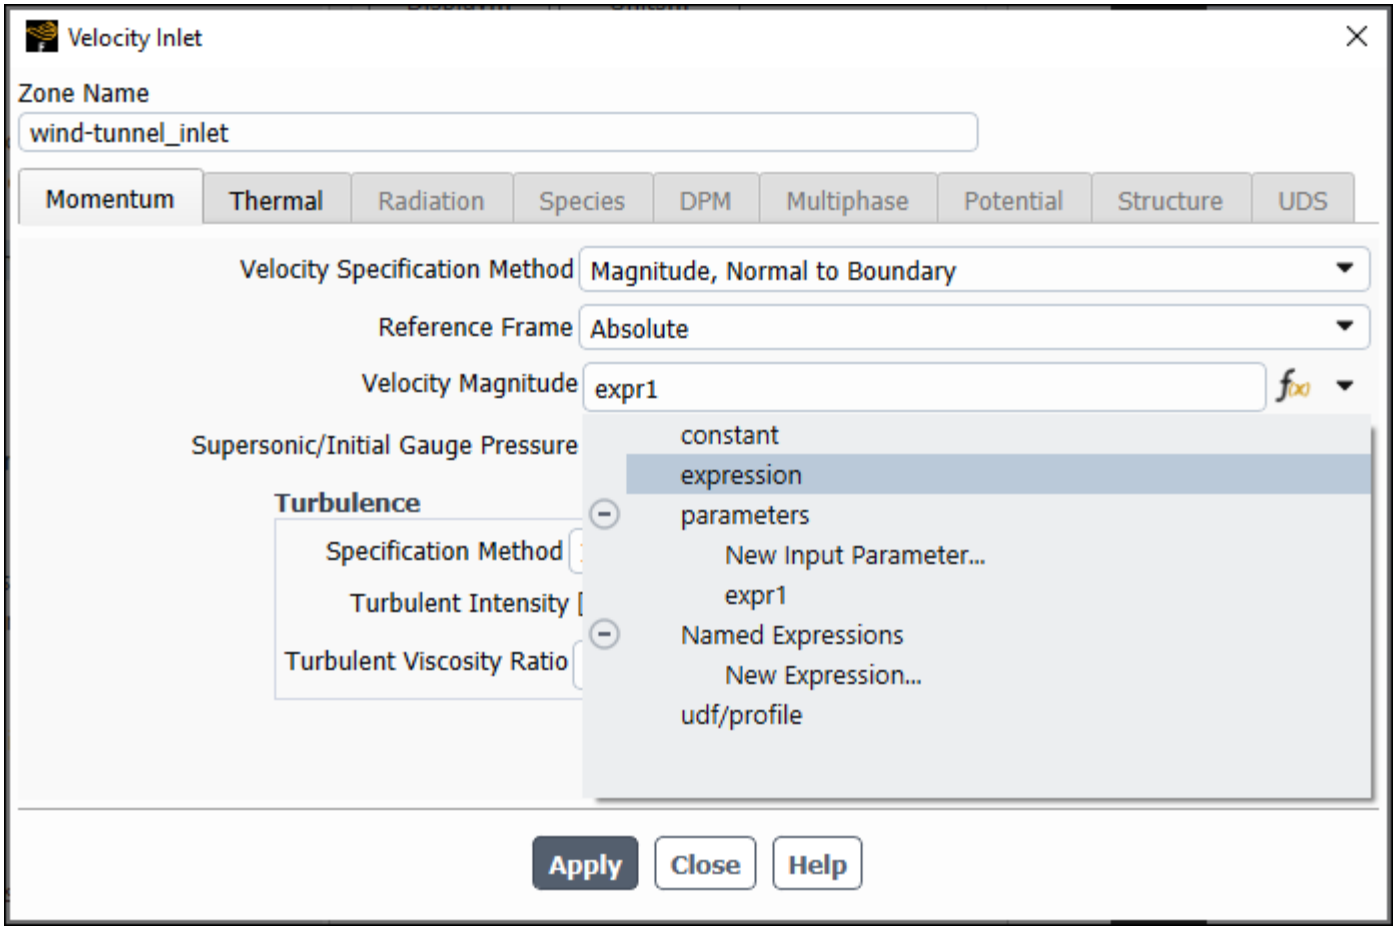
7. Click **OK** to create the expression.

The **Used In** *field lists the locations where the expression is used, including other expressions.*

Important:

When you select a named expression for a field, either as just an expression or as an input parameter, the expression only shows as being selected under **Named Expressions** or **parameters** until you save the changes and close the dialog box. When the dialog box is reopened, you will see that the expression name is now displayed in the field and **expression** is selected from the drop-down. This is only a visual change in how this selection is shown; the field is still defined using that expression as it was when it was selected earlier.

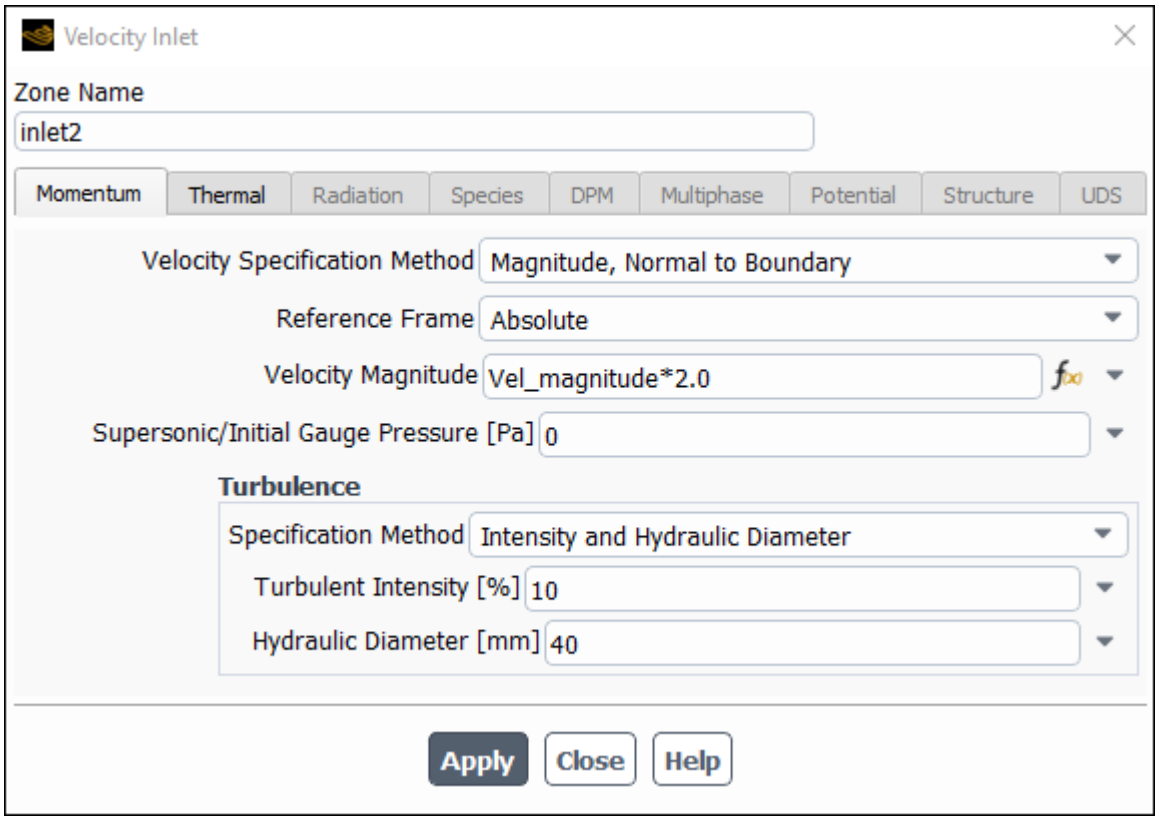
Figure 5.5: Velocity Magnitude Defined as "expr1", An Expression Input Parameter



In Figure 5.5: Velocity Magnitude Defined as "expr1", An Expression Input Parameter (p. 1032), the **Velocity Magnitude** field was previously set as an input parameter called `expr1`, but this is how it appears after the change is applied and the dialog box closed, and then re-opened.

You can use a named expression to define other expressions—both inline expressions and named expressions. For example, a named expression with the name `Vel_magnitude` can be used to setup the velocity magnitude setting of an inlet as follows:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Note:

- Expressions that are in use cannot be deleted.
- You can create and modify named expressions through the `define/named-expressions/` text command in the console.

Important:

- Expressions must be dimensionally consistent. *For example, you cannot add two quantities that have different unit dimensions.*
- Report definitions that are included in expressions and have the **Per Surface | Per Zone** option enabled, must use an **Average Over** value of `1`.

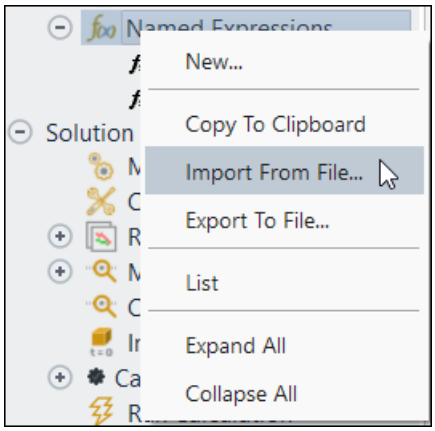
Saving and Importing Named Expressions

You have the option of saving some or all of the named expressions you create to a file for future use.

Click **Export To File...** to choose a directory and save your expression(s) to a file.

Click **Import From File...** to select and load an expression file.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



5.3.3. Context Specification

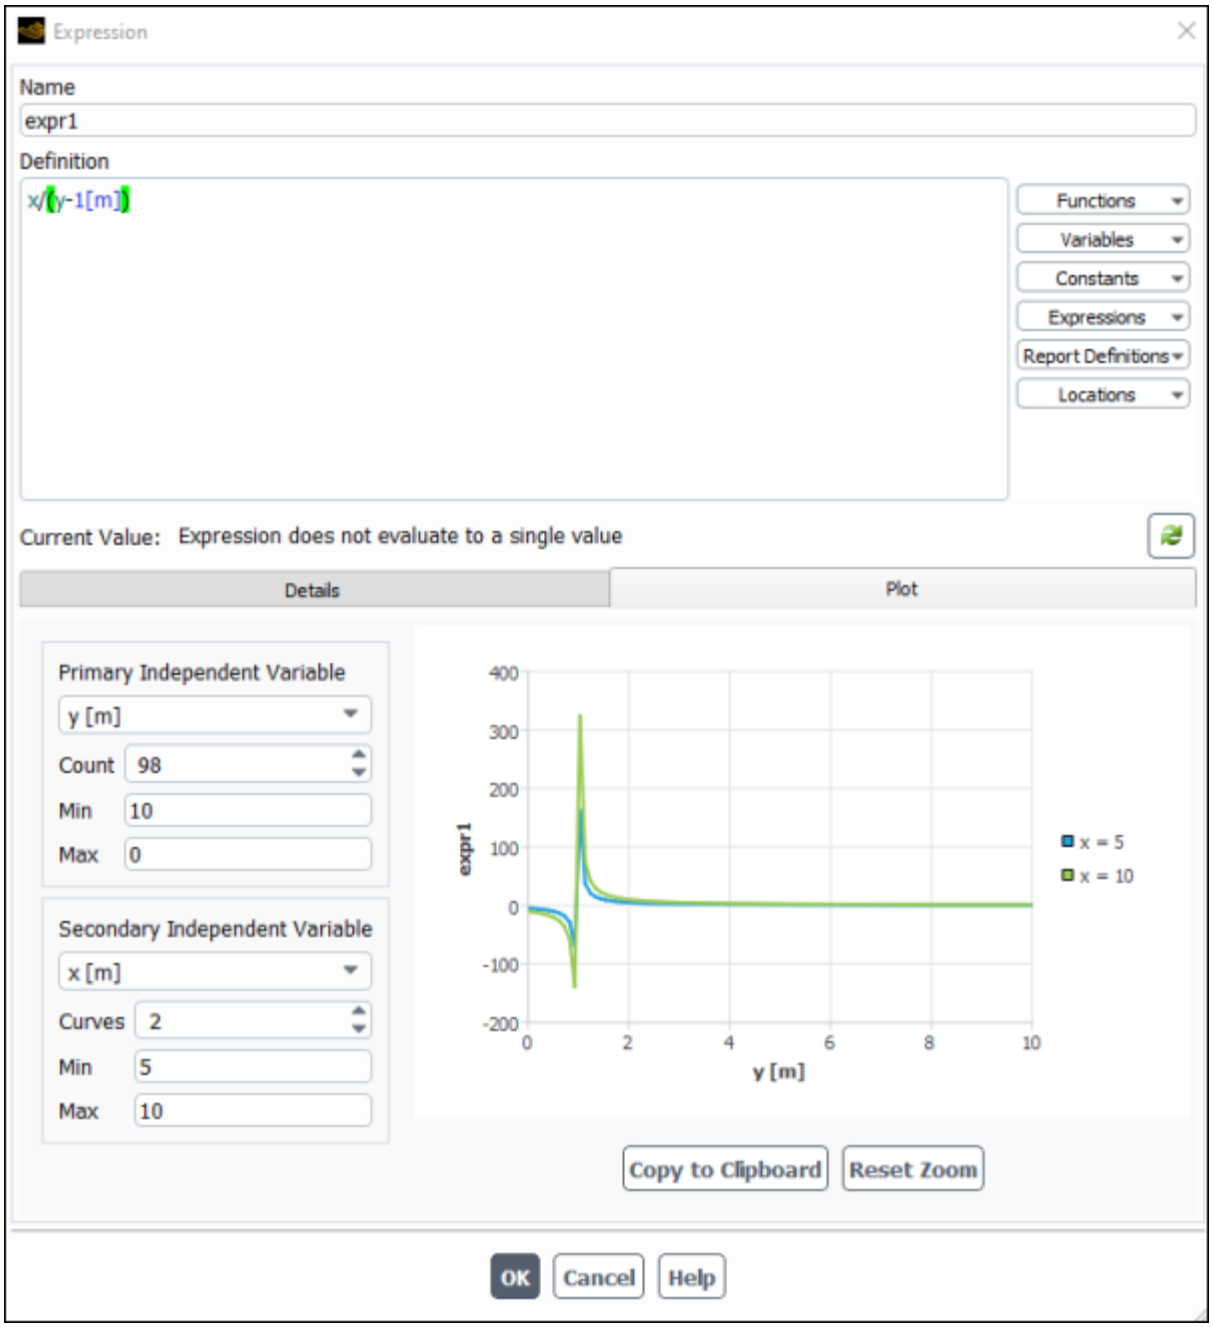
Some variables require additional context before they can be evaluated. For example, `MassFraction` requires the species context. Velocity may require phase context when it is evaluated in a multiphase simulation. The context is specified as a keyword argument to a function call on the variable. For example, `MassFraction(species="co2", phase="smoke")`.

5.3.4. Plotting Expressions

You can plot expressions to evaluate and visualize their behavior, as shown in Figure 5.6: Plotting an Expression (p. 1035).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 5.6: Plotting an Expression



To plot an expression:

1. Open the **Plot** tab.
2. Specify the **Primary Independent Variable** from the drop-down list.
3. Specify the number of plot points in the **Count** field.
4. Set the **Min** and **Max** range for the plot.
5. If you have more than one variable in your expression, you can define an additional variable as the **Secondary Independent Variable**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For the secondary variable, you can specify:

a. The number of **Curves**.

b. The **Min** and **Max** values for this variable.

6. (Optional) Click **Copy to Clipboard** to copy the plot image onto your clipboard.

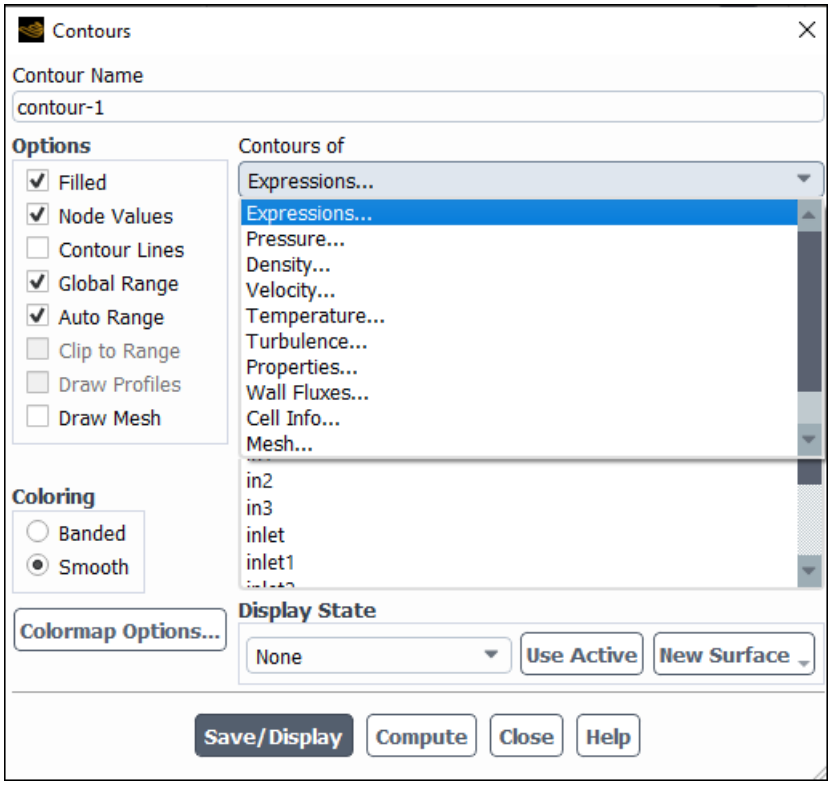
7. You can use the left and right-mouse buttons to zoom in and out on the plot. Click **Reset Zoom** to return to the original view for the plot.

5.3.5. Postprocessing Expressions

You can visualize expression results using the **Expressions...** field (Figure 5.7: Expressions... Postprocessing Field (p. 1036)) in postprocessing objects (contours, vectors, pathlines, particle tracks, XY plots). You also have the option of computing expression derivatives, which may also be visualized.

In addition to postprocessing expressions as field variables, you can also create expression volumes, which allow you to define a volume surface where you can display other field variables. Refer to Expression Volumes (p. 3825) for additional information.

Figure 5.7: Expressions... Postprocessing Field



Expressions available for postprocessing must:

- be of type **Double** or **Double Vector**. *If it is of type **Double Vector**, the components and magnitude are available for postprocessing.*

- evaluate to a field (and not a single-value)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- be fully specified. *For example, if the expression computes mass fraction, the specie must also be included in the definition (`MassFraction(species='co2')`. Similarly, for a multiphase case, the phase must be specified, where required (`VolumeFraction(phase='water')`.*

  Important:

  – For multiphase cases, the **Phase** drop-down is not relevant, because the available expressions are already fully specified. *Phase specification is not required for "mixture only" variables, such as static pressure.*

  – Expressions do not work reliably when exported to other postprocessors. They are not exported to CFD-Post.

  Note:

  While the plot displayed in the graphics window will show the units in the colormap, the **Min** and **Max** fields in the dialog box for the same plot, will not.

Computing Statistics on Expressions

You can select expressions that evaluate to a field in the **Zone-Specific Sampling Options** dialog box. Refer to Inputs for Time-Dependent Problems (p. 3631) and Data Sampling for Steady Statistics (p. 3627) for additional information on statistics.

Important:

RMSE values computed on expressions may differ from RMSE values computed on equivalent custom field functions. The difference is due to the number of significant digits used in expression computations (9 decimal places).

5.3.6. Expression Manager

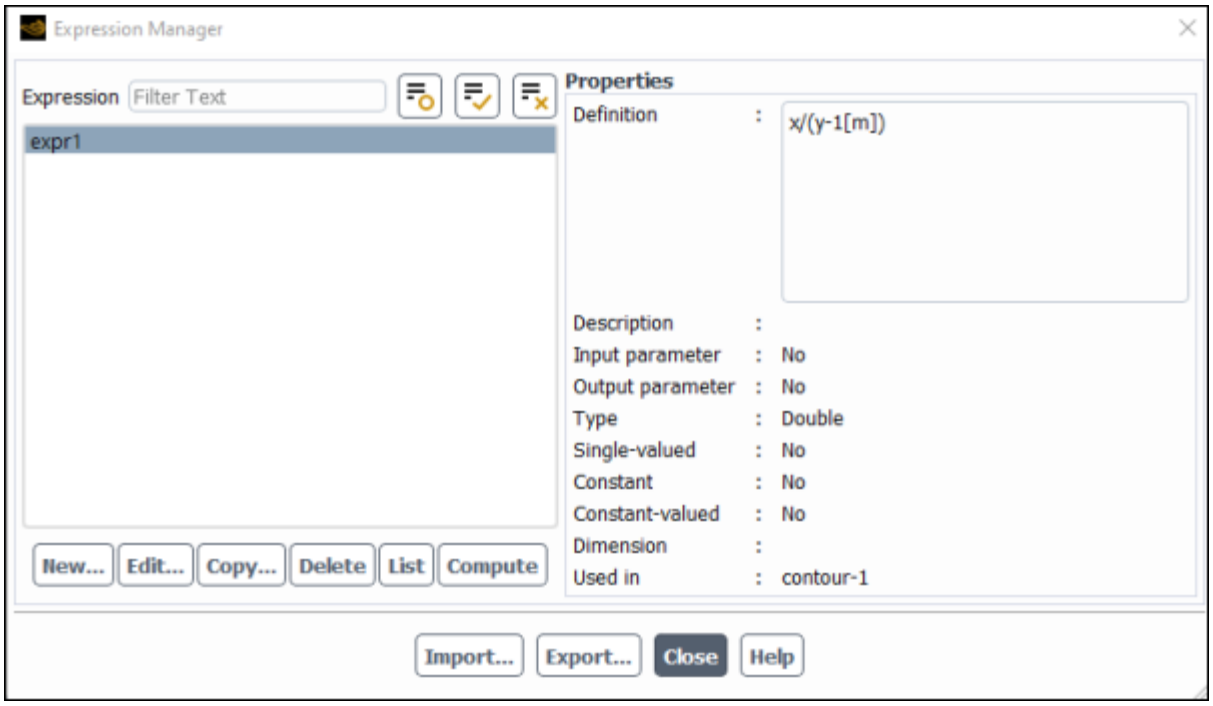
As expressions are created, they are added to the Outline View tree under the **Named Expressions** branch. You can perform various operations on defined expressions (such as copying and deleting) using context menus available via right-mouse-button click of the expression(s) in the Outline View tree. The **Expression Manager** (Figure 5.8: Expression Manager Dialog Box (p. 1038)) allows you to perform all of these operations within a single dialog box.

To use the **Expression Manager**:

1. Open the **Expression Manager** dialog box.

   Setup → Named Expressions → Manage...

Figure 5.8: Expression Manager Dialog Box



2. Select the desired expression(s) and click the relevant button to perform the desired operation. *Not all operations are available when multiple expressions are selected, for example,* ***Edit...*** *is grayed-out.*

3. Click **Close** when you are done modifying the expressions.

Refer to Expression Manager Dialog Box (p. 5412) for detailed explanations of each button function.

5.4. Expression Examples

The following are a few examples that demonstrate why or where you may want to use an expression and how you would do so for these situations.

5.4.1. Parabolic Inflow Profile

5.4.2. Time-Varied Parabolic Inflow

5.4.3. Controlled Outlet Temperature

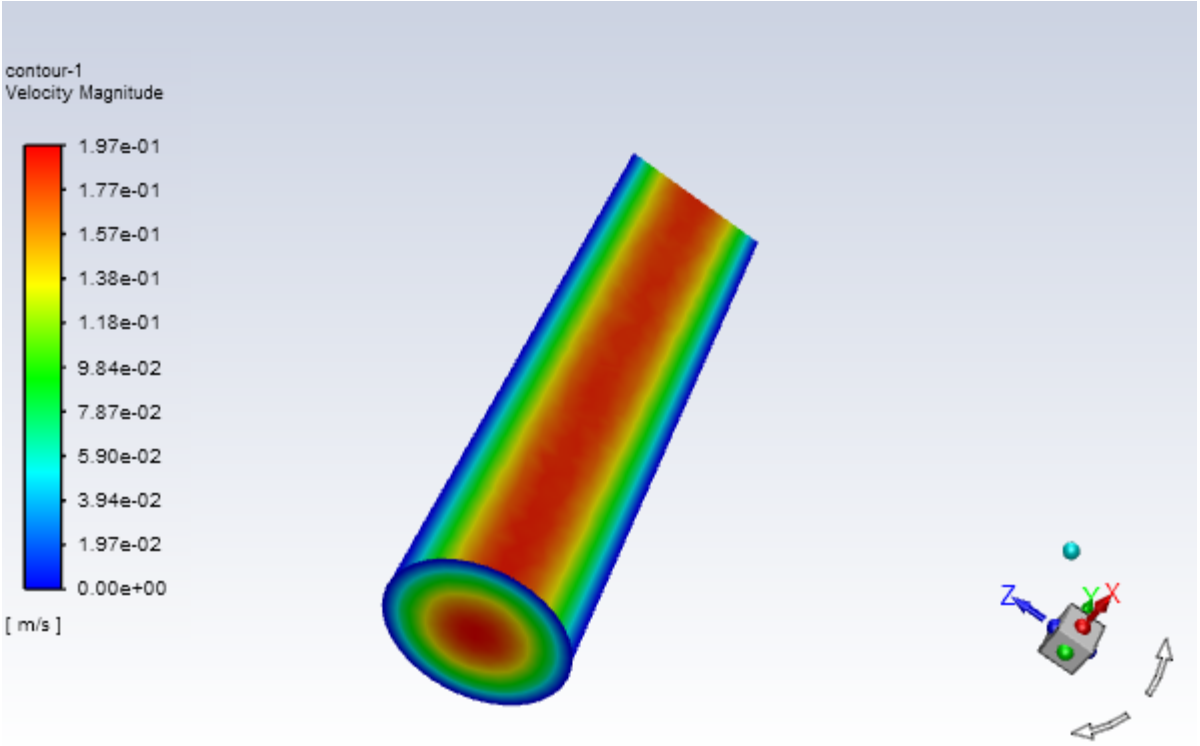
5.4.4. Computing Forces with Parameterized Angle of Attack

5.4.1. Parabolic Inflow Profile

The following example shows you how to define a parabolic inlet profile for laminar pipe flow, as shown in Figure 5.9: Contours of Velocity - Parabolic Inflow (p. 1039). In this example, the pipe is centered in the X and Z directions and the pipe axis is aligned to the Y-direction.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 5.9: Contours of Velocity - Parabolic Inflow



The expression for defining the parabolic inflow shown in Figure 5.9: Contours of Velocity - Parabolic Inflow (p. 1039) is Equation 5.1 (p. 1039),

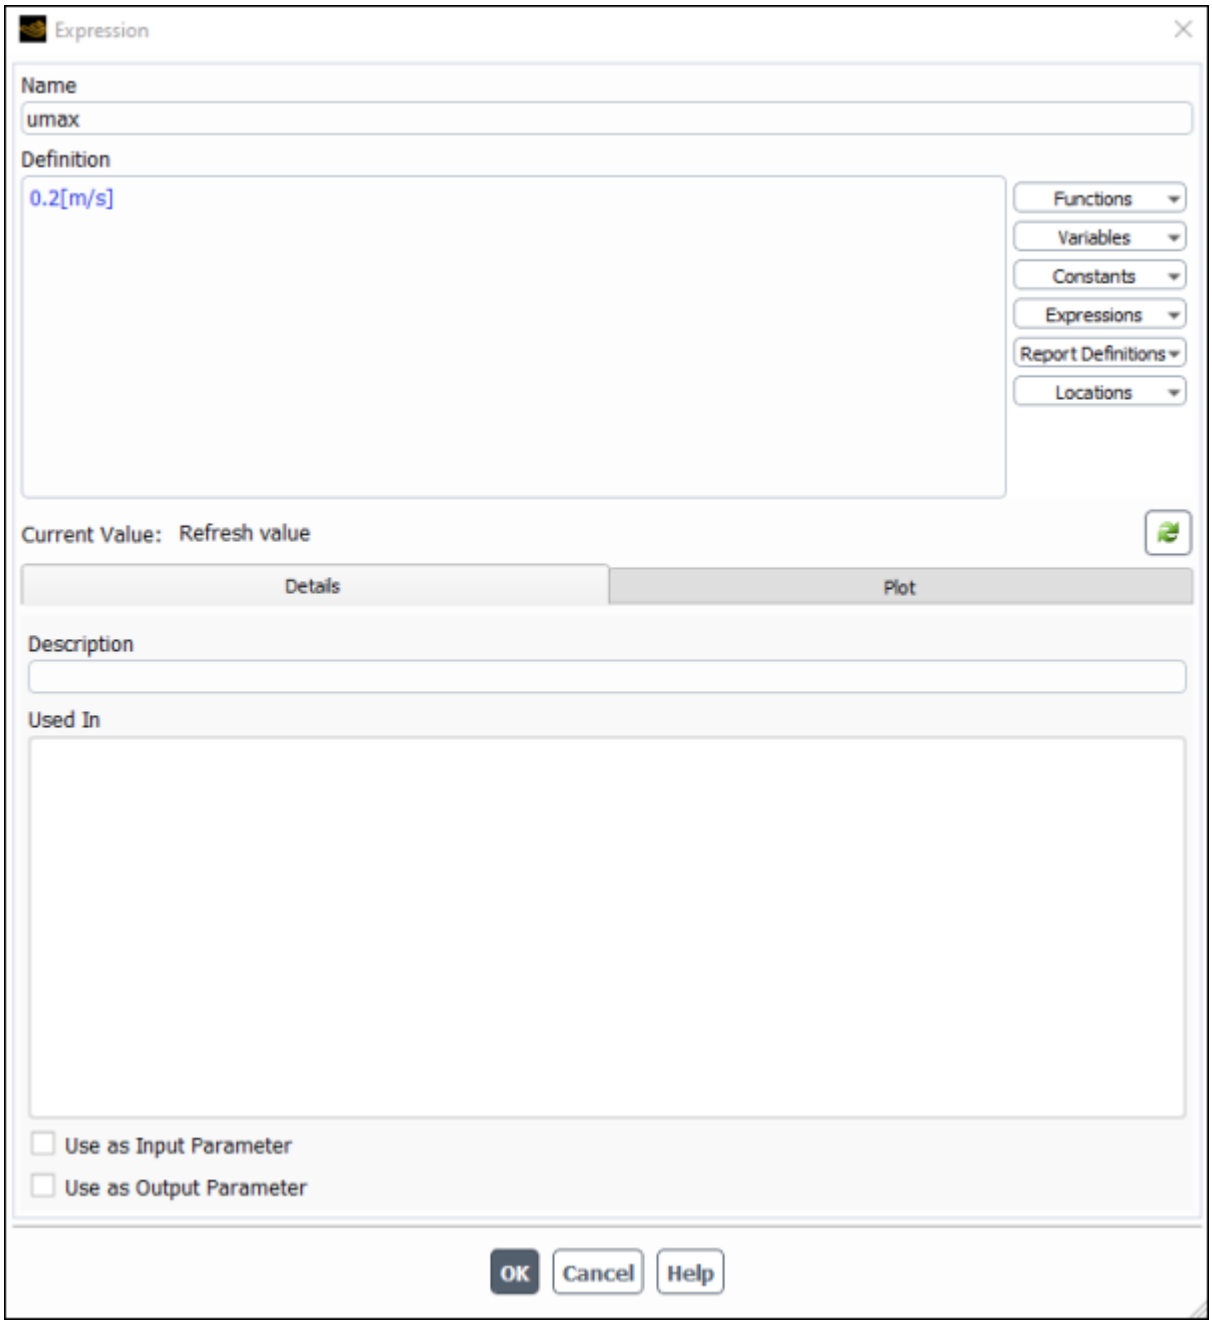
$$u_{\max}*\left(1-\left(radius/Radius\right)^{2}\right) \tag{5.1}$$

Where $u_{\max}$ is the velocity at the axis, $Radius$ is the radius of the pipe, and $radius$ is the local radial coordinate.

To fully define this example:

1. Create a named expression for the maximum velocity called **umax**.

   Setup → **Named Expressions** **New...**



a. Enter **umax** for the **Name**.

b. Enter **0.2 [m/s]** for the **Definition** and click **OK**.

2. Create an expression for the radius of the pipe.

a. Open the **Expressions** dialog box by right-clicking **Named Expressions** in the outline view tree and selecting **New...**.

b. Enter **Radius** for the **Name**.

c. Enter **sqrt(Area(["in"])/PI)** for the **Definition**. *"in" is the name of the inlet boundary. PI is the expression constant for Pi.*

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

d. Click **OK** to create the named expression.

3. Create an expression for the local radial profile.

   a. Open the **Expressions** dialog box and enter **radius** for the **Name**.

   b. Enter **sqrt(x**2+z**2)** for the **Definition**. *This expression uses the square root mathematical expression operator.*

   c. Click **OK** to create the named expression.

4. Create an expression for the inlet velocity profile. *This expression combines the other expressions you created.*

   a. Open the **Expressions** dialog box and enter **uprofile** for the **Name**.

   b. Enter **umax*(1- (radius/Radius)**2)** for the **Definition**. *You can use the **Expressions** drop-down to the right of the **Definition** box to add named expressions to your expression definition as an alternative to typing the names manually.*

   c. Click **OK** to create the named expression.

5. Assign **uprofile** to the velocity inlet.

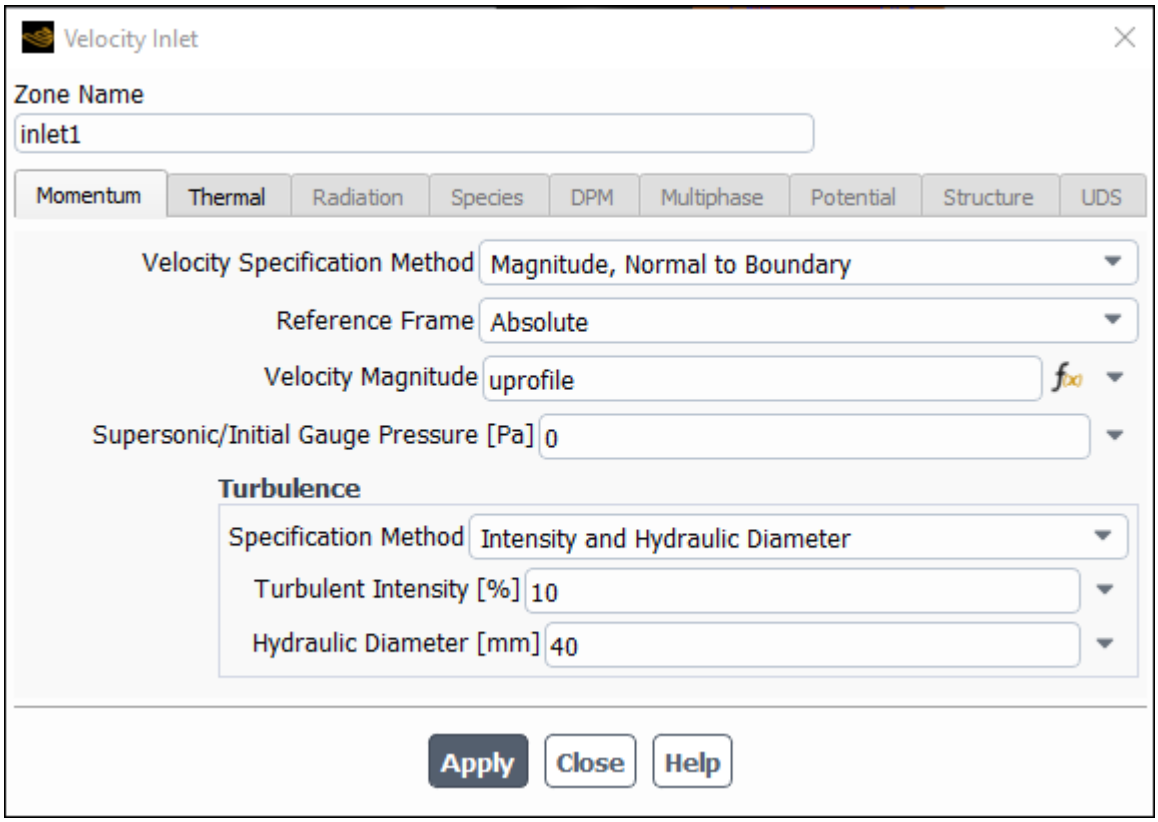
   Setup → Boundary Conditions → Inlet → in Edit...

   *You can group the boundary conditions by type to organize the boundaries and reduce the size of the list. This can be accomplished by right-clicking **Boundary Conditions** in the tree and selecting **Group By**> **Zone Type**.*

   a. Select **expression** from the drop-down to the right of **Velocity Magnitude**.

   b. Enter **uprofile** in the **Velocity Magnitude** field and click **OK**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

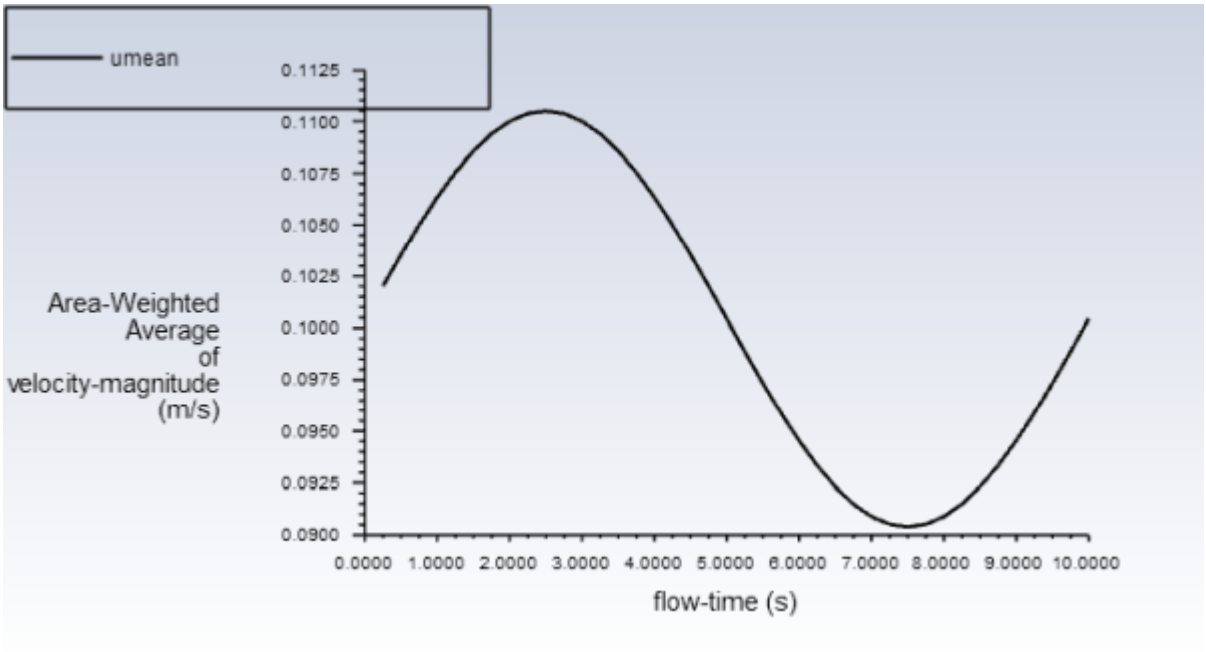


5.4.2. Time-Varied Parabolic Inflow

The following example shows you how to define a parabolic inlet profile for laminar pipe flow that varies over time (a sine function with a period of 10 seconds). The velocity profile in this example is the same as for Parabolic Inflow Profile (p. 1038) except it is for a transient simulation because the velocity varies over time. Figure 5.10: Parabolic Inflow Velocity Over Time (p. 1043) plots the area weighted average of the velocity magnitude over 10 seconds.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 5.10: Parabolic Inflow Velocity Over Time

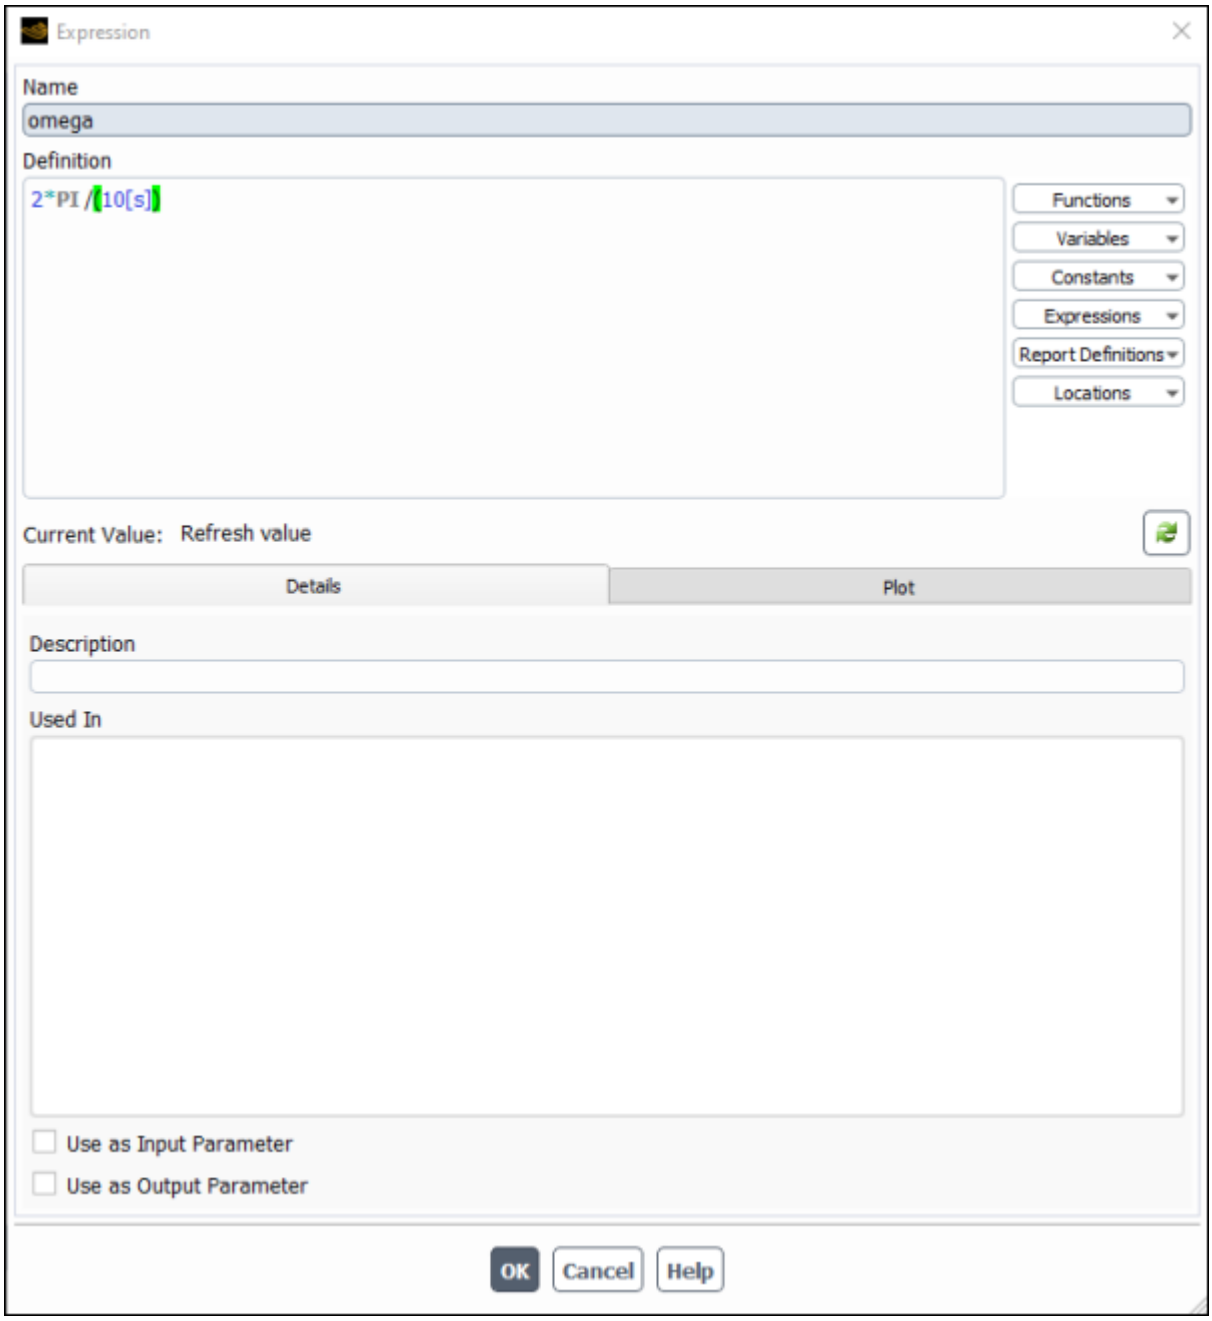


To create an expression for this time-varied velocity profile:

1. Define all of the named expressions as described in Parabolic Inflow Profile (p. 1038).
2. Create an expression for omega.

   Setup → Named Expressions → New...

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



a. Enter **omega** for the **Name**.

b. Enter **2*PI / (10[s])** for the **Definition** and click **OK**.

3. Create an expression for the velocity profile that varies over time.

   a. Open the **Expressions** dialog box and enter **uprofile_transient** for the **Name**.

   b. Enter **uprofile*(sin(omega*Time)*0.1 + 1)** for the **Definition** and click **OK**.

4. Assign **uprofile_transient** to the velocity inlet.

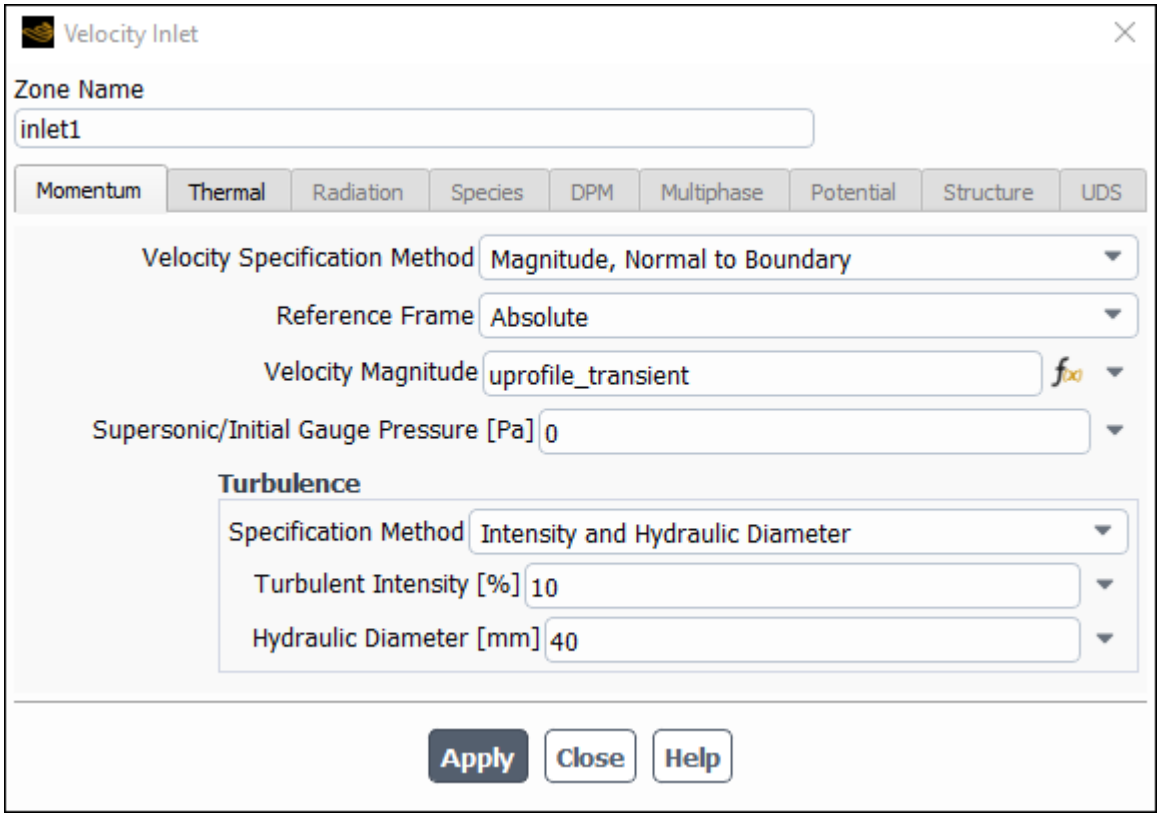
   Setup → Boundary Conditions → Inlet → in → Edit...

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can group the boundary conditions by type to organize the boundaries and reduce the size of the list. This can be accomplished by right-clicking ***Boundary Conditions*** *in the tree and selecting* ***Group By*** *>* ***Zone Type****.*

a. Select **expression** from the drop-down to the right of **Velocity Magnitude**.

b. Enter **uprofile_transient** in the **Velocity Magnitude** field and click **OK**.



5.4.3. Controlled Outlet Temperature

The following example shows you how to drive the maximum temperature at the outlet to a target temperature by varying the inlet temperature. For this scenario, a pipe with laminar flow has a part of the wall that is heated to 350 Kelvin and a target outlet temperature of 320 Kelvin (Figure 5.11: Pipe Geometry Colored by ID (Heated Wall is Green) (p. 1046) shows the portion of the wall that is heated). A controller turns on every 10th iteration (steady-state case) and adjusts the inlet temperature according to Equation 5.2 (p. 1045). In the other iterations, the controller leaves the temperature unchanged. This is achieved by using the conditional statement given in Equation 5.3 (p. 1045). Figure 5.12: Contours of Temperature (outlet is closest) (p. 1046) shows the developed temperature profile for this case.

$$T_{Adjust} = T_{InCurrent} + (T_{\mathrm{Target}} - T_{OutMax}) * relax \tag{5.2}$$

$$IF(iter<5, TStart, IF(\mathrm{mod}(iter+1,10)==0, Tadjust, TInCurrent)) \tag{5.3}$$

T_{Adjust} is the formula used to adjust the inlet temperature, $T_{InCurrent}$ is the current inlet temperature, T_{Target} is the target temperature for the outlet, which is set to 320 Kelvin, T_{OutMax} is the maximum temperature at the outlet, and $relax$ is a relaxation factor.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 5.11: Pipe Geometry Colored by ID (Heated Wall is Green)

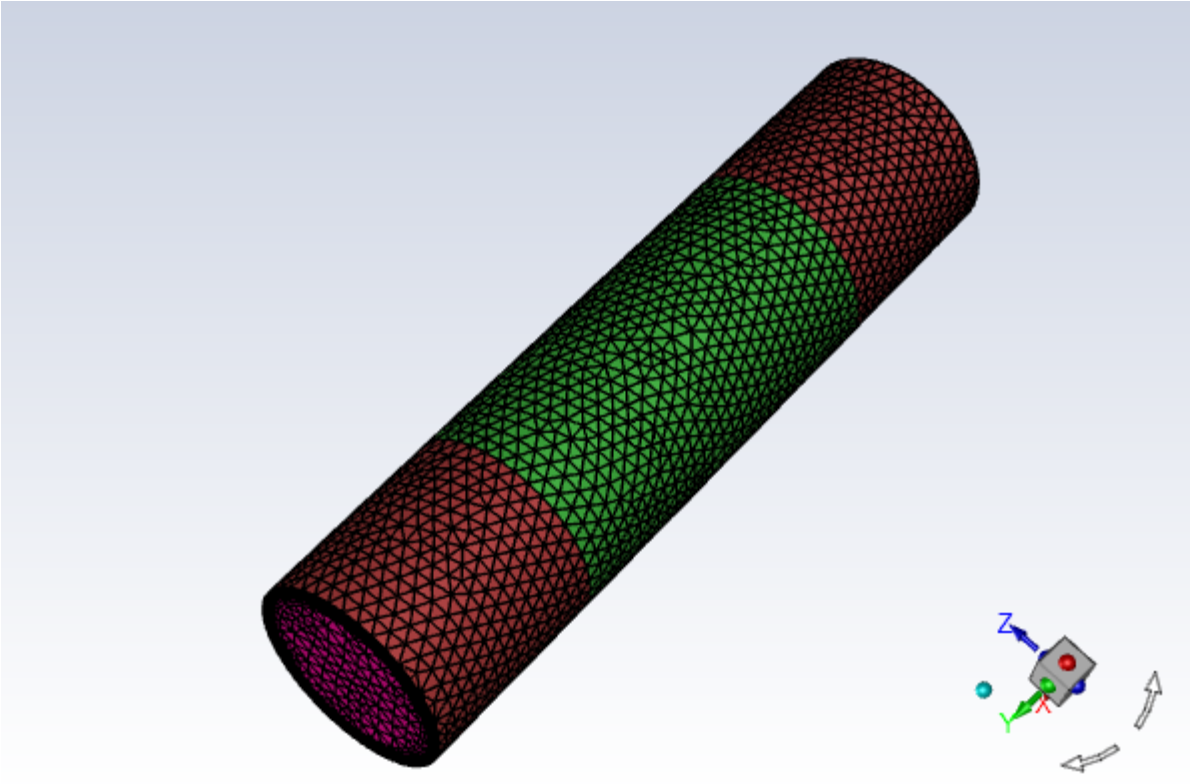


Figure 5.12: Contours of Temperature (outlet is closest)

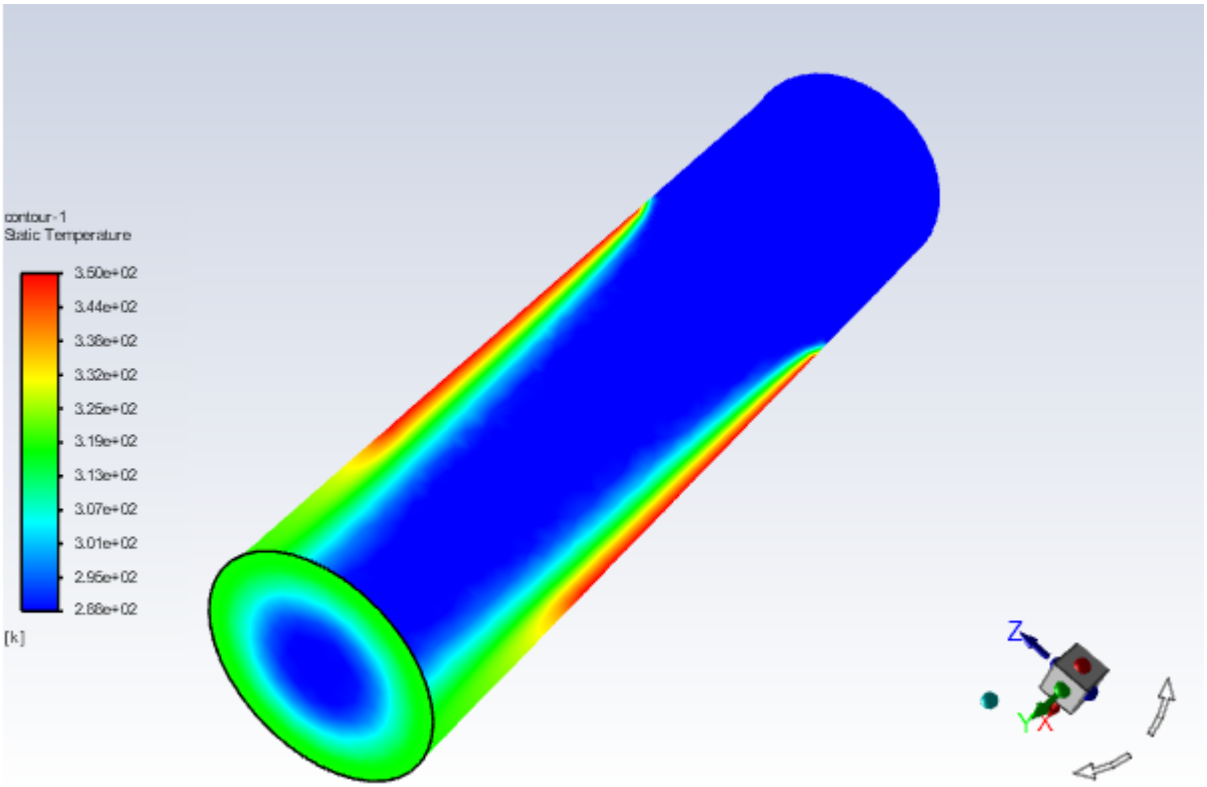
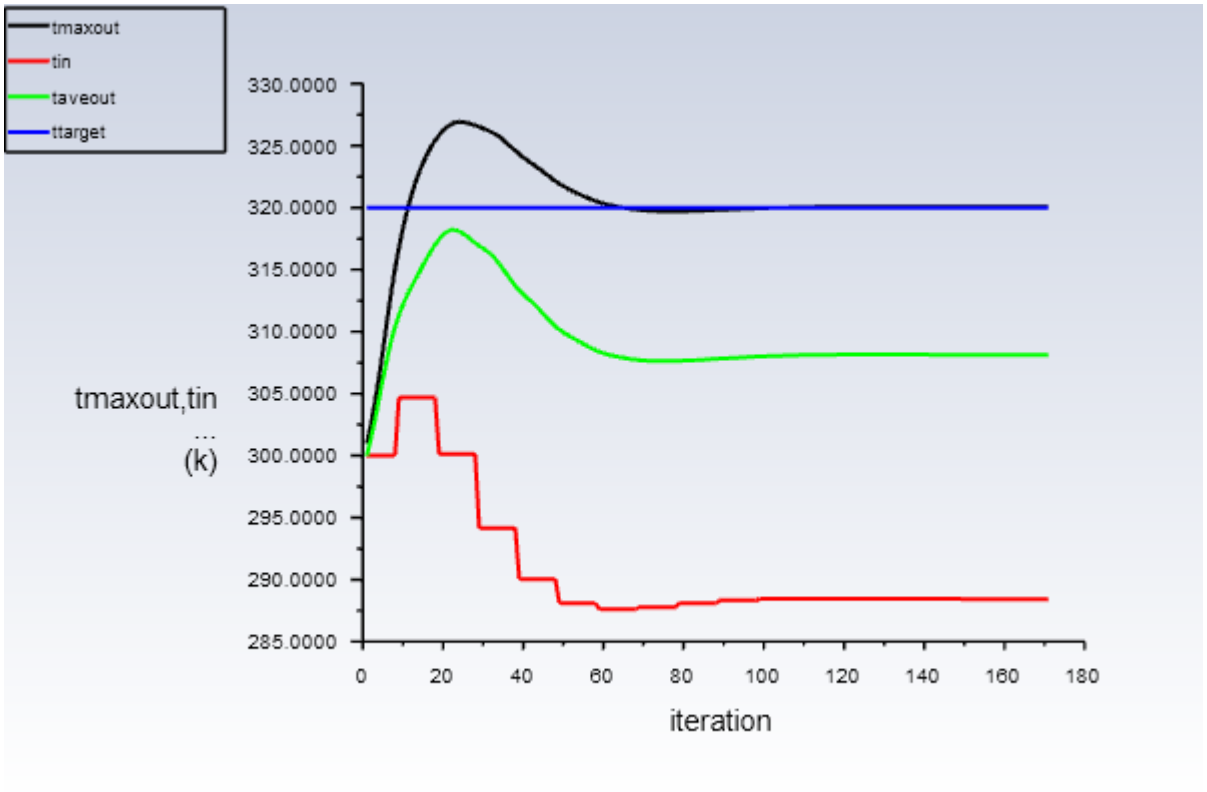


Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

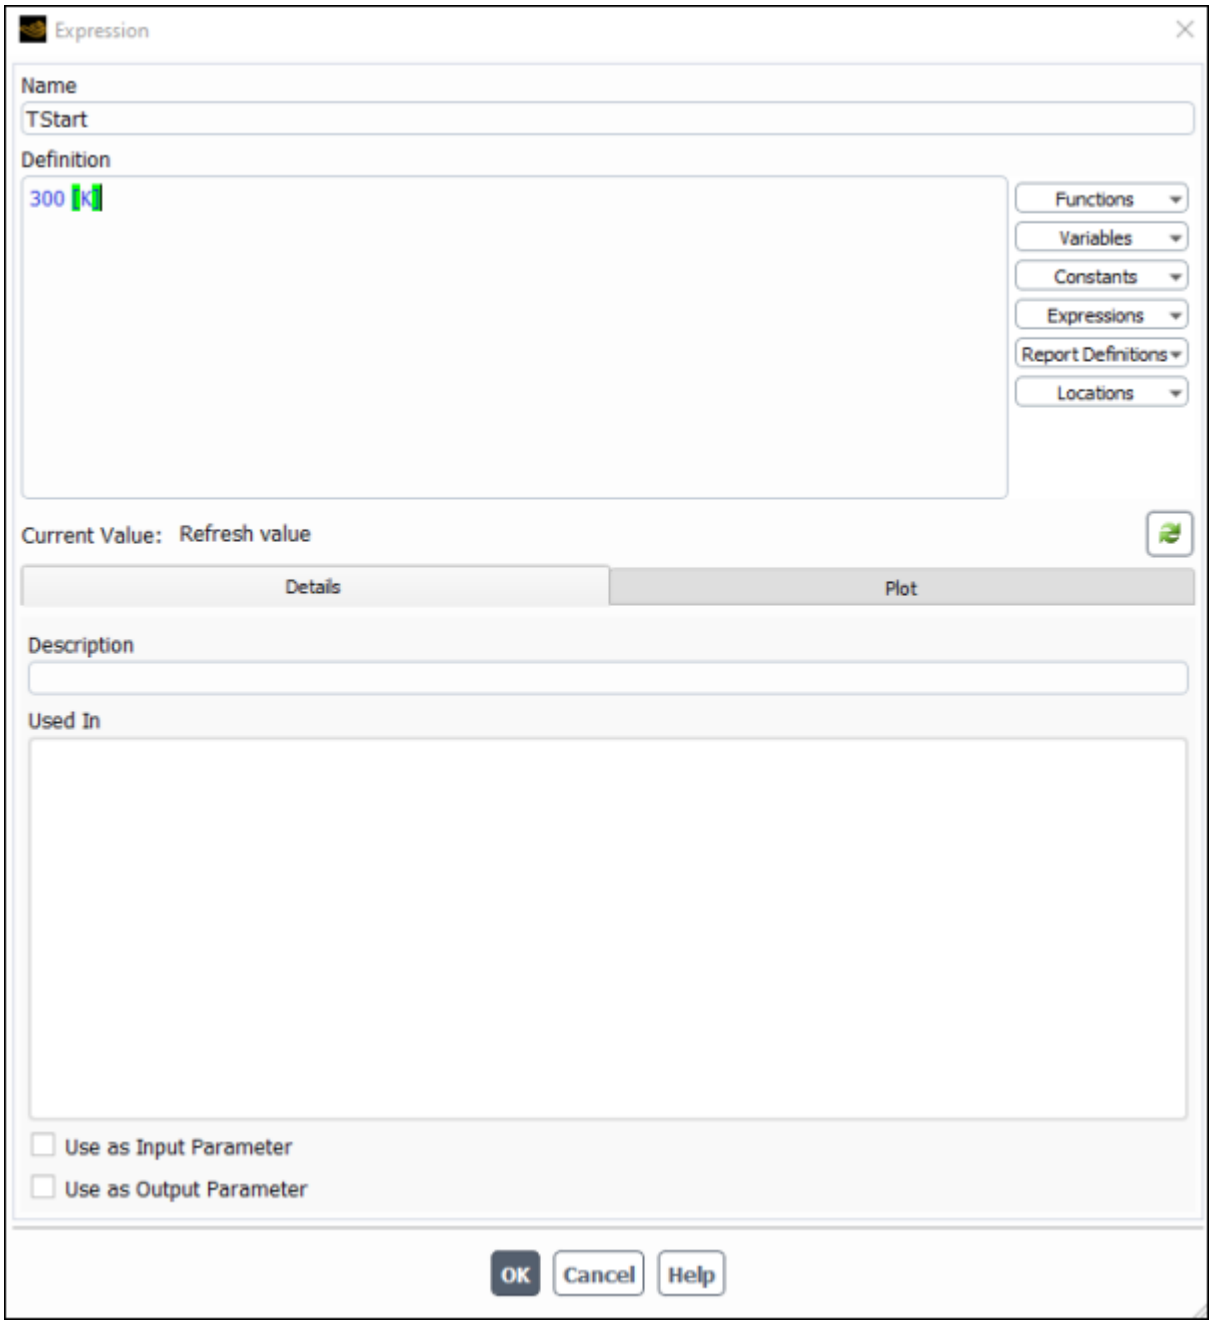
Figure 5.13: Plots of Inlet Temperature, Average Outlet Temperature, and Maximum Outlet Temperature



The following steps show how to create the expressions used in this example:

1. Create a named expression for the initial temperature, called **TStart**.

   Setup → Named Expressions New...



a. Enter **TStart** for the **Name**.

b. Enter **300 [K]** for the **Definition** and click **OK**.

2. Create an expression for the target temperature for the outlet, called **TTarget**, and set it equal to **320 [K]**. *Use the same process that you used to create **TStart**.*

3. Create an expression for the maximum temperature that occurs at the outlet, called **TMaxOut**. *In this expression you will be using a function to determine the maximum temperature.*

   a. Click the **Functions** drop-down and select **Reduction** → **Maximum**.

   b. Enter **StaticTemperature** for the first field of the function and **["out"]** for the location. The total expression should appear as **Maximum(StaticTemperature, ["out"])**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Create an expression for the current inlet temperature, called **TInCurrent**, and set it equal to **Average(StaticTemperature, ["in"], Weight=None)**. *Use a similar process to what you used to create **TMaxOut**, but with selecting the **Average** function instead.*

5. Create an expression for the relaxation factor, called **relax**, and set it equal to **0.9**.

6. Create an expression for adjusting the inlet temperature, called **TAdjust**, and set it equal to **TInCurrent + (TTarget - TMaxOut)*relax**.

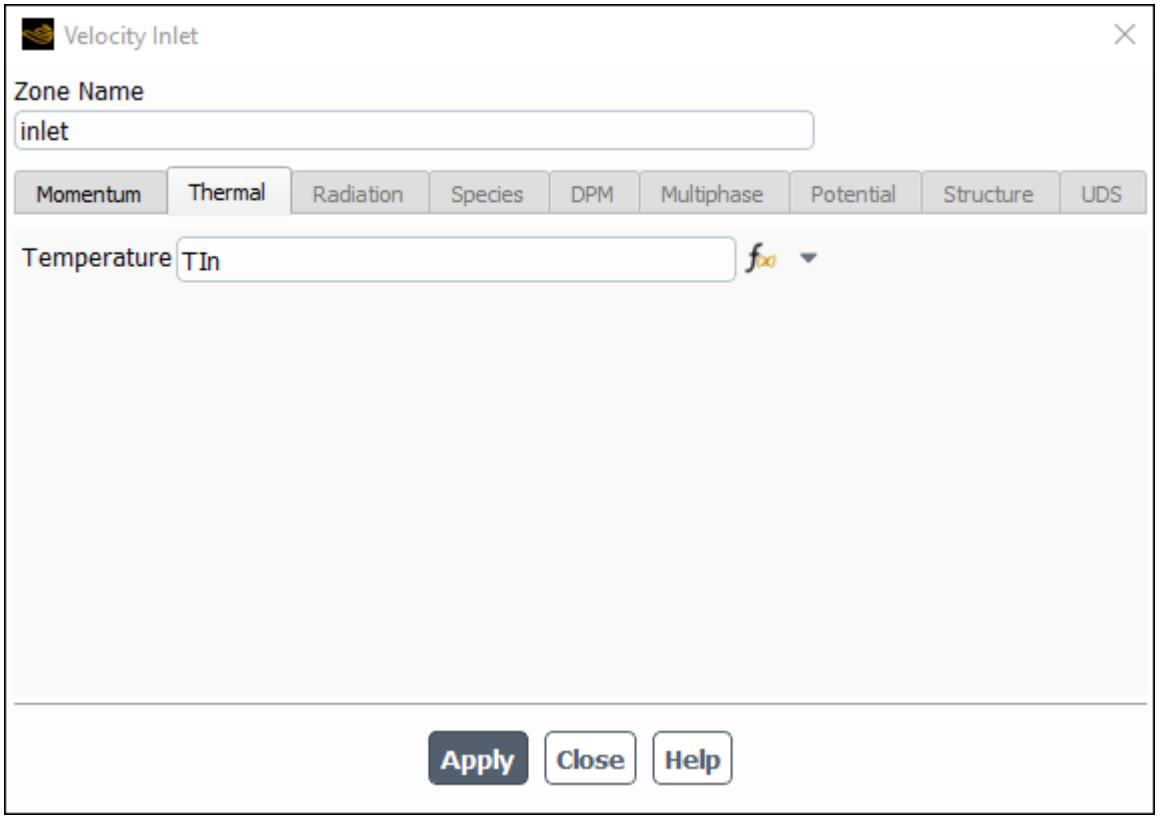
7. Create an expression for the inlet temperature, which will be called **TIn**, and set it equal to **IF(iter<5, TStart, IF(mod(iter+1, 10)==0, TAdjust, TInCurrent))**. *Use a similar process to what you used to create **TMaxOut**, but with selecting the **IF** conditional function instead.*

8. Assign **TIn** to the inlet.

   Setup → Boundary Conditions → Inlet → in → Edit...

   a. Select **expression** from the drop-down to the right of **Temperature**.

   b. Enter **TIn** in the **Temperature** field and click **OK**.



5.4.4. Computing Forces with Parameterized Angle of Attack

The following example shows you how to setup to use `dot()`, `vector()`, `moment()`, and `force()` expression operations in Ansys Fluent. Six expressions are defined: AOA, dragForce, flowDir, liftForce, moment, and totalForce.

To begin, define the angle of attack expression as an input parameter.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Open the **Expression** dialog box.

   Setup → Named Expressions → New...

   *Note that the dialog box appears as **Parameter Expression** because the setup is already completed and **Use as Input Parameter** is enabled.*

2. Enter A0A as the **Name**.

3. Enter `5[deg]` in the **Definition** field.

4. Enable **Use as Input Parameter**.

5. Click **OK** to create the angle of attack input parameter expression.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Define the flow direction.

1. Open the **Expression** dialog box.

   Setup → **Named Expressions** → **New...**

2. Enter `flowDir` as the **Name**.
3. Enter `vector(cos(AOA), sin(AOA), 0.0)` in the **Definition** field.

   Note:

   You select expressions that you have already defined, such as **AOA** from the **Expressions** drop-down list on the right-hand side of the dialog box.

4. Click **OK** to create the expression for the flow direction.

Define the total force.

1. Open the **Expression** dialog box.

   Setup → **Named Expressions** → **New...**

2. Enter `totalForce` as the **Name**.
3. Enter `Force(['wall-top', 'wall-bottom'])` in the **Definition** field.
4. Click **OK** to create the expression for the total force.

Define the moment about the centroid of the airfoil.

1. Open the **Expression** dialog box.

   Setup → **Named Expressions** → **New...**

2. Enter `moment` as the **Name**.
3. Enter `Moment(Centroid(['fluid-16'], ['wall-top', 'wall-bottom']).mag` in the **Definition** field.
4. Enable **Use as Output Parameter** to use the moment as an output parameter.
5. Click **OK** to create the expression for the total force.

Define the lift force normal to the flow.

1. Open the **Expression** dialog box.

   Setup → **Named Expressions** → **New...**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Enter `liftForce` as the **Name**.
3. Enter `dot(totalForce, vector(-flowDir.y, flowdir.x, 0))` in the **Definition** field.

   Note:

   You select expressions that you have already defined, such as **totalForce** from the **Expressions** drop-down list on the right-hand side of the dialog box.

4. Enable **Use as Output Parameter** to use the lift force as an output parameter.
5. Click **OK** to create the expression for the lift force.

Define the drag force.

1. Open the **Expression** dialog box.

   Setup → **Named Expressions** → **New...**

2. Enter `dragForce` as the **Name**.
3. Enter `dot(totalForce, flowDir)` in the **Definition** field.

   Note:

   You select expressions that you have already defined, such as **totalForce** from the **Expressions** drop-down list on the right-hand side of the dialog box.

4. Enable **Use as Output Parameter** to use the drag force as an output parameter.
5. Click **OK** to create the expression for the total force.

Now that these expressions are defined, you can include them in expression report definitions for monitoring and judging convergence.

5.5. Appendix: Supported Field Variables

Note:

Postprocessing variables related to structures and the Structural Model are only available on solid cell zones. Therefore, any computations made on variables available under **Structure...** should only include solid zones to ensure they are evaluated correctly.

Chapter 6: Reading and Manipulating Meshes

Ansys Fluent can import different types of meshes from various sources. You can modify the mesh by translating or scaling node coordinates, partitioning the domain for parallel processing, and merging or separating zones. You can convert all 3D meshes to polyhedral cells, except for pure hex meshes. Hexahedral cells are preserved during conversion. You can also obtain diagnostic information on the mesh, including memory usage and simplex, topological, and domain information. You can find out the number of nodes, faces, and cells in the mesh, determine the minimum and maximum cell volumes in the domain, and check for the proper numbers of nodes and faces per cell. These and other capabilities are described in the following sections.

6.1. Mesh Topologies

6.2. Mesh Requirements and Considerations

6.3. Mesh Sources

6.4. Reference Frames

6.5. Curvilinear Coordinate Systems

6.6. Non-Conformal Meshes

6.7. Overset Meshes

6.8. Controlling Flow in Narrow Gaps for Valves and Pumps

6.9. Checking the Mesh

6.10. Reporting Mesh Statistics

6.11. Converting the Mesh to a Polyhedral Mesh

6.12. Modifying the Mesh

See Adapting the Mesh (p. 3755) for information about adapting the mesh based on solution data and related functions, and Mesh Partitioning and Load Balancing (p. 4281) for details on partitioning the mesh for parallel processing.

6.1. Mesh Topologies

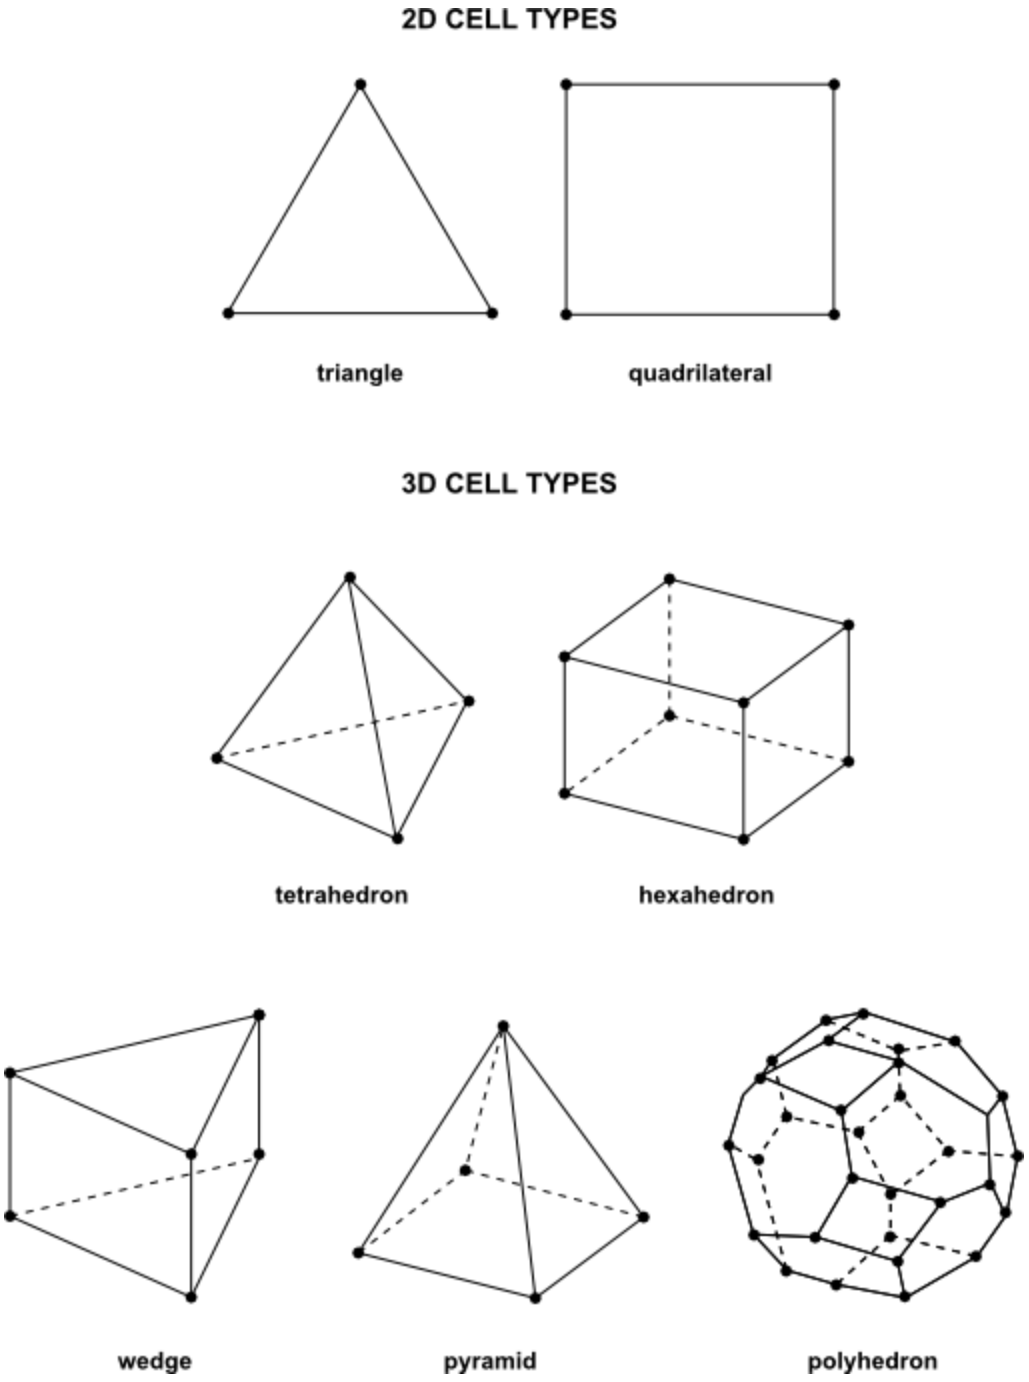
As an unstructured solver, Ansys Fluent uses internal data structures to assign an order to the cells, faces, and grid points in a mesh and to maintain contact between adjacent cells. Therefore, it does not require i,j,k indexing to locate neighboring cells. This gives you the flexibility to use the best mesh topology for your problem, as the solver does not force an overall structure or topology on the mesh.

For 2D meshes, quadrilateral and triangular cells are accepted, and for 3D meshes, hexahedral, tetrahedral, pyramid, wedge, and polyhedral cells can be used. Figure 6.1: Cell Types (p. 1104) depicts each of these cell types. Both single-block and multi-block structured meshes, as well as hybrid meshes containing quadrilateral and triangular cells or hexahedral, tetrahedral, pyramid, and wedge cells are acceptable. Ansys Fluent also can accept meshes with hanging nodes (that is, nodes on edges and faces that are not vertices of all the cells sharing those edges or faces) and hanging edges (that is, edges on faces that do not act as edges for both of the cells sharing those faces). While such hanging nodes / edges

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

can be accepted, in 3D cases by default the adjacent cells are automatically converted to polyhedra when read to remove them; if you opt to disable this conversion, you must ensure that the hanging nodes / edges are removed from interior walls. See Hanging Node Adaption in the Theory Guide for information about acceptable hanging nodes, and Removing Hanging Nodes / Edges (p. 1133) and Converting Cells with Hanging Nodes / Edges to Polyhedra (p. 1236) for details on removing hanging nodes / edges. Meshes with non-conformal boundaries (that is, meshes with multiple subdomains in which the mesh node locations at the internal subdomain boundaries are not identical) are also acceptable. For details, see Non-Conformal Meshes (p. 1149).

Figure 6.1: Cell Types



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Some examples of meshes that are valid for Ansys Fluent are presented in Examples of Acceptable Mesh Topologies (p. 1105). Different cell shapes and their face-node connectivity are explained in Face-Node Connectivity in Ansys Fluent (p. 1110). Choosing the Appropriate Mesh Type (p. 1117) explains how to choose the mesh type that is best suited for your problem.

6.1.1. Examples of Acceptable Mesh Topologies

Ansys Fluent can solve problems on a wide variety of meshes. Figure 6.2: Structured Quadrilateral Mesh for an Airfoil (p. 1105)-Figure 6.13: Polyhedral Mesh (p. 1110) show examples of meshes that are valid for Ansys Fluent.

O-type meshes, meshes with zero-thickness walls, C-type meshes, conformal block-structured meshes, multiblock structured meshes, non-conformal meshes, and unstructured triangular, tetrahedral, quadrilateral, hexahedral, and polyhedral meshes are all acceptable.

Note:

Though Ansys Fluent does not require a cyclic branch cut in an O-type mesh, it will accept a mesh that contains one.

6.1.2. Face-Node Connectivity in Ansys Fluent

This section contains information about the connectivity of faces and their related nodes in terms of node number and face number.

Face-node connectivity for the following cell shapes is explained here:

- triangular (Figure 6.14: Face and Node Numbering for Triangular Cells (p. 1111))
- quadrilateral (Figure 6.15: Face and Node Numbering for Quadrilateral Cells (p. 1112))
- tetrahedral (Figure 6.16: Face and Node Numbering for Tetrahedral Cells (p. 1113))
- wedge (Figure 6.17: Face and Node Numbering for Wedge Cells (p. 1114))
- pyramidal (Figure 6.18: Face and Node Numbering for Pyramidal Cells (p. 1115))
- hex (Figure 6.19: Face and Node Numbering for Hex Cells (p. 1116))
- polyhedral (Figure 6.20: An Example of a Polyhedral Cell (p. 1117))

This information is useful in interfacing with Ansys Fluent.

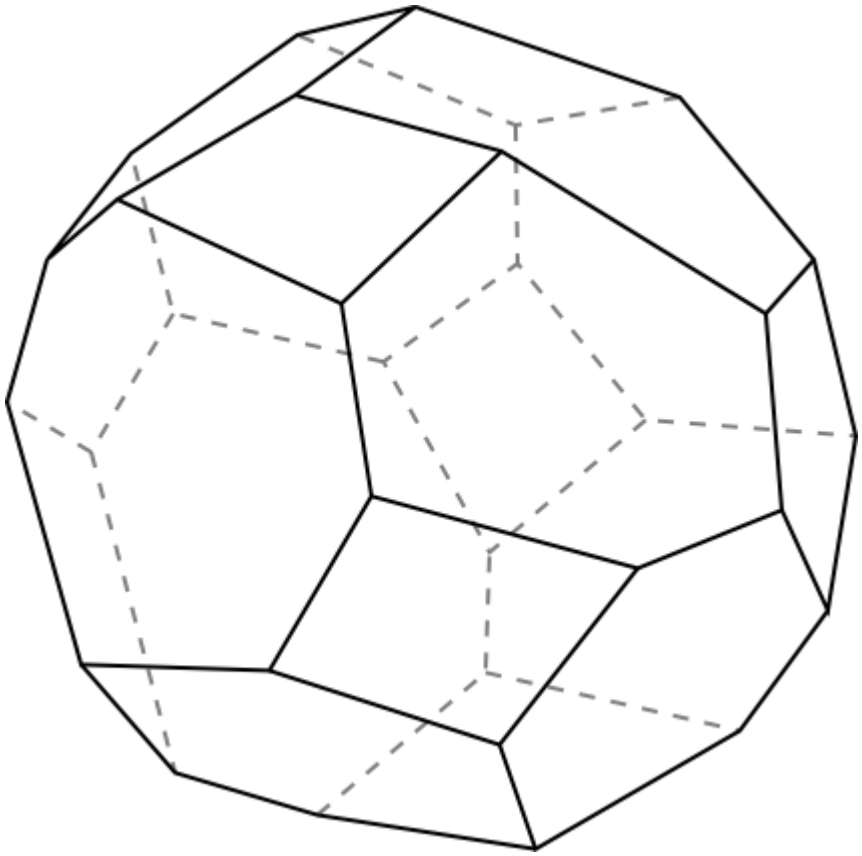
6.1.2.7. Face-Node Connectivity for Polyhedral Cells

Figure 6.20: An Example of a Polyhedral Cell



For polyhedral cells, there is no explicit face and node numbering as with the other cell types.

6.1.3. Choosing the Appropriate Mesh Type

Ansys Fluent can use meshes composed of triangular or quadrilateral cells (or a combination of the two) in 2D, and tetrahedral, hexahedral, polyhedral, pyramid, or wedge cells (or a combination of these) in 3D. The choice of which mesh type to use will depend on your application. When choosing mesh type, consider the following issues:

- setup time
- computational expense
- numerical diffusion

6.1.3.1. Setup Time

Many flow problems solved in engineering practice involve complex geometries. The creation of structured or block-structured meshes (consisting of quadrilateral or hexahedral elements) for such problems can be extremely time-consuming if not impossible. Therefore, setup time for complex geometries is the major motivation for using unstructured meshes employing triangular or tetra-

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

hedral cells. However, if your geometry is relatively simple, there may be no saving in setup time with either approach.

Other risks of using structured or block-structured meshes with complicated geometries include the oversimplification of the geometry, mesh quality issues, and a less efficient mesh distribution (for example, fine resolution in areas of less importance) that results in a high cell count.

If you already have a mesh created for a structured code, it will save you time to use this mesh in Ansys Fluent rather than regenerate it. This can be a motivation for using quadrilateral or hexahedral cells in your Ansys Fluent simulation.

Note:

Ansys Fluent has a range of filters that allow you to import structured meshes from other codes, including FLUENT 4. For details, see Mesh Sources (p. 1124).

6.1.3.2. Computational Expense

When geometries are complex or the range of length scales of the flow is large, a triangular/tetrahedral mesh can be created with far fewer cells than the equivalent mesh consisting of quadrilateral/hexahedral elements. This is because a triangular/tetrahedral mesh allows clustering of cells in selected regions of the flow domain. Structured quadrilateral/hexahedral meshes will generally force cells to be placed in regions where they are not needed. Unstructured quadrilateral/hexahedral meshes offer many of the advantages of triangular/tetrahedral meshes for moderately-complex geometries.

A characteristic of quadrilateral/hexahedral elements that might make them more economical in some situations is that they permit a much larger aspect ratio than triangular/tetrahedral cells. A large aspect ratio in a triangular/tetrahedral cell will invariably affect the skewness of the cell, which is undesirable as it may impede accuracy and convergence. Therefore, if you have a relatively simple geometry in which the flow conforms well to the shape of the geometry, such as a long thin duct, use a mesh of high-aspect-ratio quadrilateral/hexahedral cells. The mesh is likely to have far fewer cells than if you use triangular/tetrahedral cells.

Converting the entire domain of your (tetrahedral) mesh to a polyhedral mesh will result in a lower cell count than your original mesh. Although the result is a coarser mesh, convergence will generally be faster, possibly saving you some computational expense.

In summary, the following practices are generally recommended:

- For simple geometries, use quadrilateral/hexahedral meshes.
- For moderately complex geometries, use unstructured quadrilateral/hexahedral meshes.
- For relatively complex geometries, use triangular/tetrahedral meshes with wedge elements in the boundary layers.
- For extremely complex geometries, use pure triangular/tetrahedral meshes.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.1.3.3. Numerical Diffusion

A dominant source of error in multidimensional situations is numerical diffusion (false diffusion). The term *false diffusion* is used because the diffusion is not a real phenomenon, yet its effect on a flow calculation is analogous to that of increasing the real diffusion coefficient.

The following comments can be made about numerical diffusion:

- Numerical diffusion is most noticeable when the real diffusion is small, that is, when the situation is convection-dominated.
- All practical numerical schemes for solving fluid flow contain a finite amount of numerical diffusion. This is because numerical diffusion arises from truncation errors that are a consequence of representing the fluid flow equations in discrete form.
- The second-order and the MUSCL discretization scheme used in Ansys Fluent can help reduce the effects of numerical diffusion on the solution.
- The amount of numerical diffusion is inversely related to the resolution of the mesh. Therefore, one way of dealing with numerical diffusion is to refine the mesh.
- Numerical diffusion is minimized when the flow is aligned with the mesh.

  This is the most relevant to the choice of the mesh. If you use a triangular/tetrahedral mesh, the flow can *never* be aligned with the mesh. If you use a quadrilateral/hexahedral mesh, this situation might occur, but *not for complex flows*. It is only in a *simple* flow, such as the flow through a long duct, in which you can rely on a quadrilateral/hexahedral mesh to minimize numerical diffusion. In such situations, it is advantageous to use a quadrilateral/hexahedral mesh, since you will be able to get a better solution with fewer cells than if you were using a triangular/tetrahedral mesh.
- If you would like higher resolution for a gradient that is perpendicular to a wall, you can create prism layers with higher aspect ratios near the wall.

6.2. Mesh Requirements and Considerations

This section contains information about special geometry/mesh requirements and general comments on mesh quality.

6.2.1. Geometry/Mesh Requirements

6.2.2. Mesh Quality

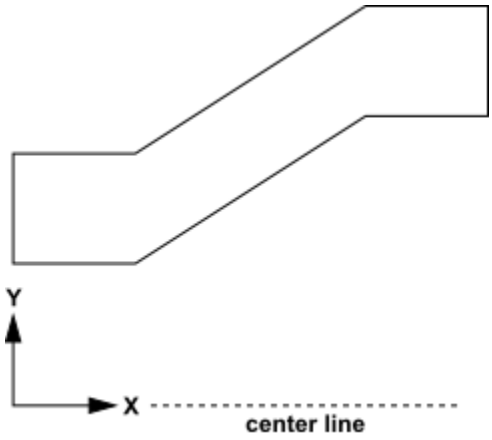
6.2.1. Geometry/Mesh Requirements

You should be aware of the following geometry setup and mesh construction requirements at the beginning of your problem setup:

- Axisymmetric geometries must be defined such that the axis of rotation is the x axis of the Cartesian coordinates used to define the geometry (Figure 6.21: Setup of Axisymmetric Geometries with the x Axis as the Centerline (p. 1120)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.21: Setup of Axisymmetric Geometries with the x Axis as the Centerline



- Ansys Fluent allows you to set up periodic boundaries using either conformal or non-conformal periodic zones. For conformal periodic boundaries, the periodic zones must have identical meshes.

  The conformal periodic boundary zones can be created in the meshing mode of Fluent or GAMBIT when you are generating the volume mesh. See the Fluent Meshing section of the User's Guide or the GAMBIT Modeling Guide for more information.

  You can also use the solution mode of Fluent to create a periodic boundary zone pair from two conformal zones, as well as a periodic interface from non-conformal zones; the latter is necessary if you created your mesh using a CAD package that is not able to produce true periodic boundaries. For details on creating such interfaces, see Creating Periodic Zones and Interfaces (p. 1246).

6.2.2. Mesh Quality

The quality of the mesh plays a significant role in the accuracy and stability of the numerical computation. Regardless of the type of mesh used in your domain, checking the quality of your mesh is essential. One important indicator of mesh quality that Ansys Fluent allows you to check is a quantity referred to as the orthogonality. In order to determine the orthogonality of a given cell, the following quantities are calculated for each face i:

- the normalized dot product of the area vector of a face ($\vec{A}_i$) and a vector from the centroid of the cell to the centroid of that face ($\vec{f}_i$):

$$\frac{\vec{A}_i \cdot \vec{f}_i}{|\vec{A}_i||\vec{f}_i|} \tag{6.1}$$

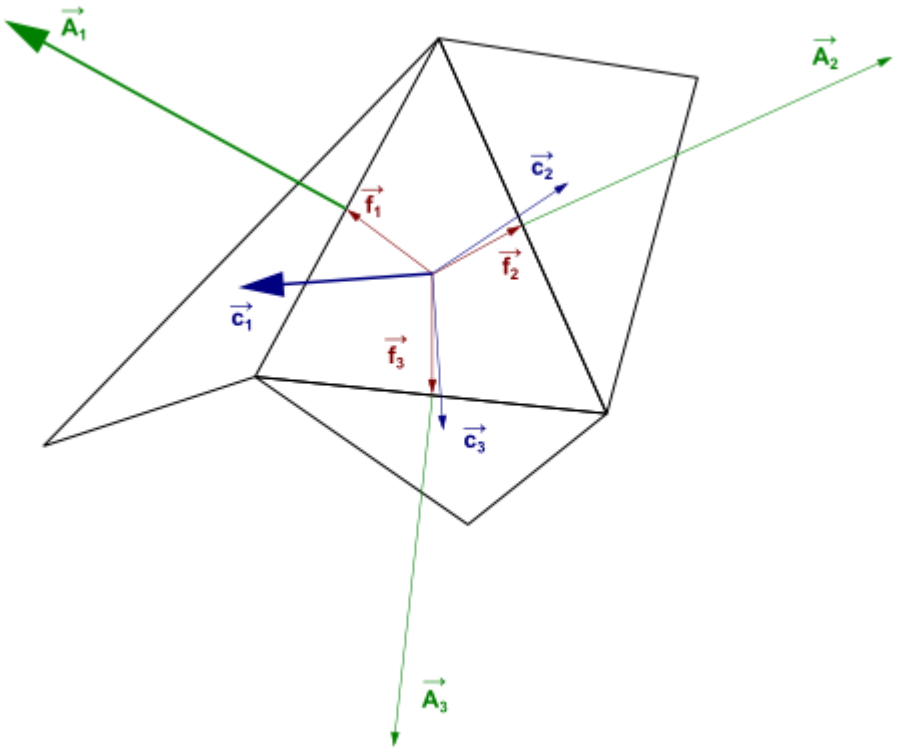
- the normalized dot product of the area vector of a face ($\vec{A}_i$) and a vector from the centroid of the cell to the centroid of the adjacent cell that shares that face ($\vec{c}_i$):

$$\frac{\vec{A}_i \cdot \vec{c}_i}{|\vec{A}_i||\vec{c}_i|} \tag{6.2}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The minimum value that results from calculating Equation 6.1 (p. 1120) and Equation 6.2 (p. 1120) for all of the faces is then defined as the orthogonality for the cell. Therefore, the worst cells will have an orthogonality closer to 0 and the best cells will have an orthogonality closer to 1. Figure 6.22: The Vectors Used to Compute Orthogonality (p. 1121) illustrates the relevant vectors.

Figure 6.22: The Vectors Used to Compute Orthogonality



This calculation of the orthogonality is used in (but is not always equal to) a metric referred to as the "orthogonal quality". By default, the orthogonal quality depends on the cell type:

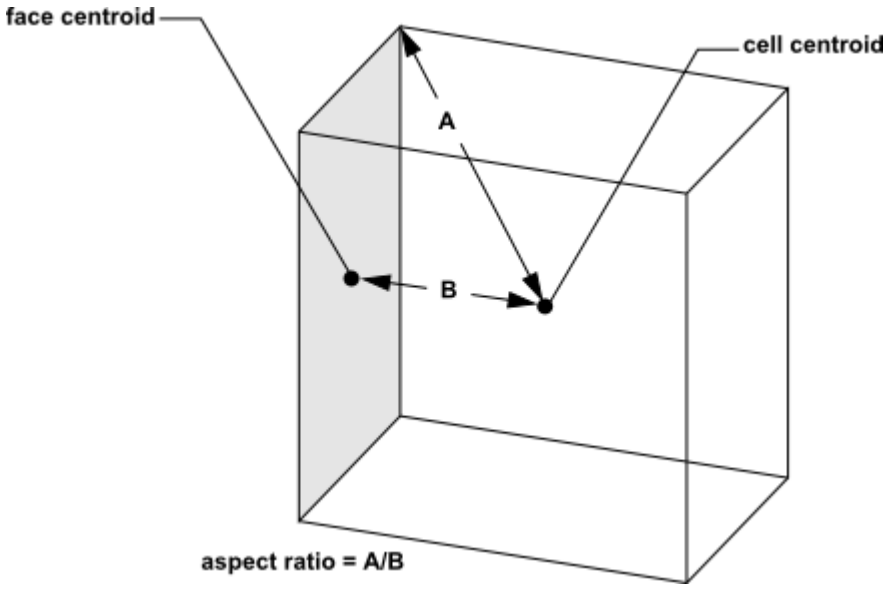
- For tetrahedral, prism, and pyramid cells, the orthogonal quality is the minimum of the orthogonality and (1- cell skewness).
- For hexahedral and polyhedral cells, the orthogonal quality is the same as the orthogonality.

Note that you can use the following text command to specify that the orthogonal quality uses an enhanced definition: `mesh/enhanced-orthogonal-quality?`. When enabled, the orthogonal quality is defined using a variety quality measures, including: the orthogonality of a face relative to vectors from the cell centroid to the face centroid and to the neighboring cell centroid; a metric that detects poor cell shape at a local edge (such as twisting and/or concavity); and the variation of normals between the faces that can be constructed from the cell face. This enhanced definition is optimal for evaluating thin prism cells.

Another important indicator of the mesh quality is the aspect ratio. The aspect ratio is a measure of the stretching of a cell. It is computed as the ratio of the maximum value to the minimum value of any of the following distances: the normal distances between the cell centroid and face centroids (computed as a dot product of the distance vector and the face normal), and the distances between the cell centroid and nodes. For a unit cube (see Figure 6.23: Calculating the Aspect Ratio for a Unit Cube (p. 1122)), the maximum distance is 0.866, and the minimum distance is 0.5, so the aspect ratio is 1.732. This type of definition can be applied on any type of mesh, including polyhedral.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.23: Calculating the Aspect Ratio for a Unit Cube



To check the quality of your mesh, you can use the **Report Quality** button in the **General** task page:

Setup → **General** → **Report Quality**

A message will be displayed in the console, such as the example that follows:

```
Mesh Quality:
 Orthogonal Quality ranges from 0 to 1, where values close to 0 correspond to low quality.
Minimum Orthogonal Quality = 6.07960e-01
Maximum Aspect Ratio = 5.42664e+00
```

If you would like more information about the quality displayed in the console (including additional quality metrics and the zones that have the cells with the lowest quality), set the `mesh/check-verbosity` text command to `2` (valid values are `0`, `1`, `2`) prior to using the **Report Quality** button.

You can also get information about the number of cells and cell quality on a per cell zone basis. This can allow you to diagnose which cell zone contains poor quality cells.

Setup → **Cell Zone Conditions** → **<Zone Type>** **Info**

*You can also perform the same **Info** check on individual cell zones.*

For information about how to improve poor quality cells, see Repairing Meshes (p. 1224). For information about avoiding divergence when cells with poor face orthogonality are near coupled two-sided walls, see Orthogonality-Based Secondary Gradient Limiting at Coupled Two-Sided Walls (p. 1451).

When evaluating whether the quality of your mesh is sufficient for the problem you are modeling, it is important to consider attributes such as mesh element distribution, cell shape, smoothness, and flow-field dependency. These attributes are described in the sections that follow.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.2.2.1. Mesh Element Distribution

Since you are discretely defining a continuous domain, the degree to which the salient features of the flow (such as shear layers, separated regions, shock waves, boundary layers, and mixing zones) are resolved depends on the density and distribution of mesh elements. In many cases, poor resolution in critical regions can dramatically affect results. For example, the prediction of separation due to an adverse pressure gradient depends heavily on the resolution of the boundary layer upstream of the point of separation.

Resolution of the boundary layer (that is, mesh spacing near walls) also plays a significant role in the accuracy of the computed wall shear stress and heat transfer coefficient. This is particularly true in laminar flows where the mesh adjacent to the wall should obey

$$y_p\sqrt{\frac{u_\infty}{\nu x}} \leq 1 \tag{6.3}$$

where

y_p = distance to the wall from the adjacent cell centroid

u_∞ = free-stream velocity

ν = kinematic viscosity of the fluid

x = distance along the wall from the starting point of the boundary layer

Equation 6.3 (p. 1123) is based upon the Blasius solution for laminar flow over a flat plate at zero incidence [132] (p. 5662).

Proper resolution of the mesh for turbulent flows is also very important. Due to the strong interaction of the mean flow and turbulence, the numerical results for turbulent flows tend to be more susceptible to mesh element distribution than those for laminar flows. In the near-wall region, different mesh resolutions are required depending on the near-wall model being used. See Model Hierarchy (p. 2044) for guidelines.

In general, no flow passage should be represented by fewer than 5 cells. Most cases will require many more cells to adequately resolve the passage. In regions of large gradients, as in shear layers or mixing zones, the mesh should be fine enough to minimize the change in the flow variables from cell to cell. Unfortunately, it is very difficult to determine the locations of important flow features in advance. Moreover, the mesh resolution in most complicated 3D flow fields will be constrained by CPU time and computer resource limitations (that is, memory and disk space). Although accuracy increases with larger meshes, the CPU and memory requirements to compute the solution and postprocess the results also increase. Solution-adaptive mesh refinement can be used to increase and/or decrease mesh density based on the evolving flow field, and therefore provides the potential for more economical use of grid points (and hence reduced time and resource requirements). See Adapting the Mesh (p. 3755) for information on solution adaption.

6.2.2.2. Cell Quality

The quality of the cell (including its orthogonal quality, aspect ratio, and skewness) also has a significant impact on the accuracy of the numerical solution.

- *Orthogonal quality* is computed as described in Mesh Quality (p. 1120). The worst cells will have an orthogonal quality closer to 0, with the best cells closer to 1. The minimum orthogonal quality for all types of cells should be more than 0.01, with an average value that is significantly higher.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- *Aspect ratio* is a measure of the stretching of the cell. As discussed in Computational Expense (p. 1118), for highly anisotropic flows, extreme aspect ratios may yield accurate results with fewer cells. Generally, it is best to avoid sudden and large changes in cell aspect ratios in areas where the flow field exhibit large changes or strong gradients.

- *Skewness* is defined as the difference between the shape of the cell and the shape of an equilateral cell of equivalent volume. Highly skewed cells can decrease accuracy and destabilize the solution. For example, optimal quadrilateral meshes will have vertex angles close to 90 degrees, while triangular meshes should preferably have angles of close to 60 degrees and have all angles less than 90 degrees. A general rule is that the maximum skewness for a triangular/tetrahedral mesh in most flows should be kept below 0.95, with an average value that is significantly lower. A maximum value above 0.95 may lead to convergence difficulties and may require changing the solver controls, such as reducing under-relaxation factors and/or switching to the pressure-based coupled solver.

Cell size change and face warp are additional quality measure that could affect stability and accuracy. See the Fluent Meshing section of the User's Guide for more details.

6.2.2.3. Smoothness

Truncation error is the difference between the partial derivatives in the governing equations and their discrete approximations. Rapid changes in cell volume between adjacent cells translate into larger truncation errors. Ansys Fluent provides the capability to improve the smoothness by refining the mesh based on the change in cell volume or the gradient of cell volume. For information on marking cells by cell volume and then refining the mesh, see Volume (p. 3840) and Refining and Coarsening (p. 3759).

6.2.2.4. Flow-Field Dependency

The effect of resolution, smoothness, and cell shape on the accuracy and stability of the solution process is dependent on the flow field being simulated. For example, very skewed cells can be tolerated in benign flow regions, but can be very damaging in regions with strong flow gradients.

Since the locations of strong flow gradients generally cannot be determined a priori, you should strive to achieve a high-quality mesh over the entire flow domain.

6.3. Mesh Sources

Since Ansys Fluent can handle a number of different mesh topologies, there are many sources from which you can obtain a mesh to be used in your simulation. You can generate a mesh using Ansys Meshing, the meshing mode of Fluent, Fluent Meshing, GAMBIT, GeoMesh, PreBFC, ICEM CFD, I-deas, NASTRAN, PATRAN, ARIES, Mechanical APDL, CFX, or other preprocessors. You can also use the mesh contained in a Fluent/UNS, RAMPANT, or FLUENT 4 case file. You can also prepare multiple mesh files and combine them to create a single mesh.

6.3.1. Ansys Meshing Mesh Files

6.3.2. Fluent Meshing Mode Mesh Files

6.3.3. Fluent Meshing Mesh Files

6.3.4. GAMBIT Mesh Files

6.3.5. GeoMesh Mesh Files

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.3.6. PreBFC Mesh Files
6.3.7. ICEM CFD Mesh Files
6.3.8. I-deas Universal Files
6.3.9. NASTRAN Files
6.3.10. PATRAN Neutral Files
6.3.11. Mechanical APDL Files
6.3.12. CFX Files
6.3.13. Using the fe2ram Filter to Convert Files
6.3.14. Removing Hanging Nodes / Edges
6.3.15. Fluent/UNS and RAMPANT Case Files
6.3.16. FLUENT 4 Case Files
6.3.17. Ansys FIDAP Neutral Files
6.3.18. Reading Multiple Mesh/Case/Data Files
6.3.19. Reading Surface Mesh Files

6.3.1. Ansys Meshing Mesh Files

You can use Ansys Meshing to create your mesh. Follow the meshing procedure and export to the Ansys Fluent mesh format (see Fluent Mesh Export in the Ansys Meshing User's Guide for details). To import the mesh into Fluent, use the **File/Read/Mesh...** ribbon tab item (as described in Reading Mesh Files (p. 929)).

6.3.2. Fluent Meshing Mode Mesh Files

You can use the meshing mode of Fluent (which was previously a stand-alone program named Fluent Meshing) to create 3D unstructured triangular/tetrahedral meshes from boundary or surface meshes. Switch to meshing mode and then follow the meshing procedure described in the Fluent Meshing section of the User's Guide. You can save your mesh using the **File/Write/Mesh...** menu item.

Then switch to the solution mode to set up the case file for the transferred mesh, or import the saved mesh into a new Fluent session using the **File/Read/Mesh...** ribbon tab item (as described in Reading Mesh Files (p. 929)).

For information about switching between meshing and solution modes, see Switching Between Meshing and Solution Modes (p. 205) in the Getting Started (p. 1) part of this manual.

6.3.3. Fluent Meshing Mesh Files

Prior to version 14.5, Fluent Meshing was a stand-alone product that was used to create 3D unstructured triangular/tetrahedral meshes from boundary or surface meshes. Fluent Meshing has been integrated as the Fluent meshing mode. To import meshes created by Fluent Meshing into Fluent, use the **File/Read/Mesh...** ribbon tab item (as described in Reading Mesh Files (p. 929)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.3.4. GAMBIT Mesh Files

You can use GAMBIT to create 2D and 3D structured/unstructured/hybrid meshes. To create any of these meshes for Ansys Fluent, follow the procedure described in the GAMBIT Modeling Guide, and export your mesh in Fluent 5/6 format. All such meshes can be imported directly into Ansys Fluent using the **File/Read/Mesh...** ribbon tab item, as described in Reading Mesh Files (p. 929).

6.3.5. GeoMesh Mesh Files

You can use GeoMesh to create complete 2D quadrilateral or triangular meshes, 3D hexahedral meshes, and triangular surface meshes for 3D tetrahedral meshes. To create any of these meshes for Ansys Fluent, follow the procedure described in the GeoMesh User's Guide.

To complete the generation of a 3D tetrahedral mesh, read the surface mesh into the meshing mode of Fluent and generate the volume mesh there (see the Fluent Meshing section of the User's Guide for details). All other meshes can be read directly into the solution mode of Fluent. Use the **File/Read/Mesh...** ribbon tab item to read the mesh files, as described in Reading Mesh Files (p. 929).

6.3.6. PreBFC Mesh Files

You can use PreBFC to create two different types of meshes for Ansys Fluent, structured quadrilateral/hexahedral and unstructured triangular/tetrahedral.

6.3.6.1. Structured Mesh Files

To generate a structured 2D or 3D mesh, follow the procedure described in the PreBFC User's Guide (Chapters 6 and 7). The resulting mesh will contain quadrilateral (2D) or hexahedral (3D) elements. Do not specify more than 70 wall zones and 35 inlet zones.

To import the mesh, use the **File/Import/PreBFC File...** ribbon tab item.

To manually convert a file in PreBFC format to a legacy mesh file suitable for Ansys Fluent, enter the following command:

`utility fl42seg` *input_filename output_filename*

The output file produced can be read into Ansys Fluent using the **File/Read/Mesh...** ribbon tab item, as described in Reading Mesh Files (p. 929).

6.3.6.2. Unstructured Triangular and Tetrahedral Mesh Files

To generate an unstructured 2D mesh, follow the procedure described in the PreBFC User's Guide. Save the mesh file in the RAMPANT format using the `MESH-RAMPANT/TGRID` command. The current Ansys Fluent format is the same as the RAMPANT format. The resulting mesh will contain triangular elements. To import the mesh, use the **File/Read/Mesh...** ribbon tab item, as described in Reading Mesh Files (p. 929).

To generate a 3D unstructured tetrahedral mesh, follow the procedure described in Chapter 8 of the PreBFC User's Guide for generating a surface mesh. Then read the surface mesh into the meshing mode of Fluent, and complete the mesh generation there. See the Fluent Meshing section of the User's Guide for details.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.3.7. ICEM CFD Mesh Files

You can use ICEM CFD to create structured meshes in FLUENT 4 format and unstructured meshes in RAMPANT format.

- To import a FLUENT 4 mesh, follow the instructions in FLUENT 4 Case Files (p. 1134).
- To import a RAMPANT mesh, use the **File/Read/Mesh...** ribbon tab item, as described in Reading Mesh Files (p. 929).

The current Ansys Fluent format is the same as the RAMPANT format,*not* the FLUENT 4 format. After reading a triangular or tetrahedral ICEM CFD volume mesh, improve its quality through smoothing (as described in Quality-Based Smoothing (p. 1269)).

6.3.8. I-deas Universal Files

You can import an I-deas Universal file into Ansys Fluent in three different ways.

- Generate an I-deas surface or volume mesh containing triangular, quadrilateral, tetrahedral, wedge and/or hexahedral elements. Import it into the meshing mode of Fluent using the commands described in the Fluent Meshing section of the User's Guide. Adhere to the restrictions described in Appendix B: Mesh File Format (p. 839) in the Fluent Meshing section of the User's Guide. In meshing mode, complete the mesh generation (if necessary); then you can switch to the solution mode of Fluent or read it into a new Fluent session as described in Fluent Meshing Mode Mesh Files (p. 1125).
- Generate an I-deas volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements. Import it directly using the **File/Import/I-deas Universal...** ribbon tab item.
- Generate an I-deas volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements. Use the `fe2ram` filter to convert the Universal file to the format used by Ansys Fluent. To convert an input file in I-deas Universal format to an output file in Ansys Fluent format, follow the instructions below in Using the fe2ram Filter to Convert Files (p. 1132). After the output file is written, read it into Ansys Fluent using the **File/Read/Mesh...** ribbon tab item, as described in Reading Mesh Files (p. 929).

6.3.8.1. Recognized I-deas Datasets

The following Universal file datasets are recognized by the Ansys Fluent mesh import utility:

- **Node Coordinates** dataset number 15, 781, 2411
- **Elements** dataset number 71, 780, 2412
- **Permanent Groups** dataset number 752, 2417, 2429, 2430, 2432, 2435

For 2D volume meshes, the elements must exist in a constant z plane.

Note:

The mesh area or mesh volume datasets are *not* recognized. This implies that writing multiple mesh areas/volumes to a single Universal file may confuse Ansys Fluent.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.3.8.2. Grouping Nodes to Create Face Zones

Nodes are grouped in I-deas using the `Group` command to create boundary face zones. In Ansys Fluent, boundary conditions are applied to each zone. Faces that contain the nodes in a group are gathered into a single zone. It is important not to group nodes of internal faces with nodes of boundary faces.

One technique is to generate groups automatically based on curves or mesh areas—that is, every curve or mesh area will be a different zone in Ansys Fluent. You may also create the groups manually, generating groups consisting of all nodes related to a given curve (2D) or mesh area (3D).

6.3.8.3. Grouping Elements to Create Cell Zones

Elements in I-deas are grouped using the `Group` command to create the multiple cell zones. All elements grouped together are placed in a single cell zone in Ansys Fluent. If the elements are not grouped, Ansys Fluent will place all the cells into a single zone.

6.3.8.4. Deleting Duplicate Nodes

I-deas may generate duplicate or coincident nodes in the process of creating elements. These nodes must be removed in I-deas before writing the universal file for import into Ansys Fluent.

6.3.9. NASTRAN Files

There are three different ways in which you can import a NASTRAN file into Ansys Fluent:

- You can generate a NASTRAN surface or volume mesh containing triangular, quadrilateral, tetrahedral, wedge, and/or hexahedral elements, and import it into the meshing mode of Fluent using the commands described in the Fluent Meshing section of the User's Guide. Adhere to the restrictions described in Appendix B: Mesh File Format (p. 839) in the Fluent Meshing section of the User's Guide. In meshing mode, complete the mesh generation (if necessary); then you can switch to the solution mode of Fluent or read it into a new Fluent session as described in Fluent Meshing Mode Mesh Files (p. 1125).

- You can generate a NASTRAN volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements, and import it directly using the **File/Import/NASTRAN** ribbon tab item, as described in NASTRAN Files (p. 957).

- You can generate a NASTRAN volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements. Then use the `fe2ram` filter to convert the NASTRAN file to the format used by Ansys Fluent. To convert an input file in NASTRAN format to an output file in Ansys Fluent format, follow the instructions below in Using the fe2ram Filter to Convert Files (p. 1132). After the output file has been written, you can read it into Ansys Fluent using the **File/Read/Mesh...** ribbon tab item, as described in Reading Mesh Files (p. 929).

After reading a triangular or tetrahedral NASTRAN volume mesh using the latter methods, improve its quality through smoothing (as described in Quality-Based Smoothing (p. 1269)).

6.3.9.1. Recognized NASTRAN Bulk Data Entries

The following NASTRAN file datasets are recognized by the Ansys Fluent mesh import utility:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **GRID** single-precision node coordinates
- **GRID*** double-precision node coordinates
- **CBAR** line elements
- **CTETRA, CTRIA3** tetrahedral and triangular elements
- **CHEXA, CQUAD4, CPENTA** hexahedral, quadrilateral, and wedge elements

For 2D volume meshes, the elements must exist in a constant z plane.

6.3.9.2. Deleting Duplicate Nodes

NASTRAN may generate duplicate or coincident nodes in the process of creating elements. These nodes must be removed in NASTRAN before writing the file for import into Ansys Fluent.

6.3.10. PATRAN Neutral Files

There are three different ways in which you can import a PATRAN Neutral file into Ansys Fluent.

- You can generate a PATRAN surface or volume mesh containing triangular, quadrilateral, tetrahedral, wedge, and/or hexahedral elements, and import it into the meshing mode of Fluent using the commands described in the Fluent Meshing section of the User's Guide. Adhere to the restrictions described in Appendix B: Mesh File Format (p. 839) in the Fluent Meshing section of the User's Guide. In meshing mode, complete the mesh generation (if necessary); then you can switch to the solution mode of Fluent or read it into a new Fluent session as described in Fluent Meshing Mode Mesh Files (p. 1125).
- You can generate a PATRAN volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements (grouping nodes with the same component-group name) and import it directly to Ansys Fluent by selecting the **File/Import/PATRAN** ribbon tab item.
- You can generate a PATRAN volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements and then use the `fe2ram` filter to convert the Neutral file into the format used by Ansys Fluent. To convert an input file in PATRAN Neutral format to an output file in Ansys Fluent format, follow the instructions below in Using the fe2ram Filter to Convert Files (p. 1132). After the output file has been written, you can read it into Ansys Fluent using the **File/Read/Mesh...** ribbon tab item, as described in Reading Mesh Files (p. 929).

After reading a triangular or tetrahedral PATRAN volume mesh using the latter methods, improve its quality through smoothing (as described in Quality-Based Smoothing (p. 1269)).

Important:

To retain a zone type during PATRAN Neutral file import, add the abbreviated form of the "zone-type" before the "zone-name", as shown below:

Zone Type in Ansys Fluent	Zone Name for PATRAN export (zone-type) - (zone-name)
mass-flow-inlet	m-f-i-zone-name
pressure-outlet	p-o-zone-name

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Zone Type in Ansys Fluent	Zone Name for PATRAN export (zone-type) - (zone-name)
fan	fan-zone-name
velocity-inlet	v-i-zone-name
pressure-far-field	p-f-f-zone-name
solid	solid-zone-name
fluid	fluid-zone-name

6.3.10.1. Recognized PATRAN Datasets

The following PATRAN Neutral file packet types are recognized by the Ansys Fluent mesh import utility:

- **Node Data** Packet Type 01
- **Element Data** Packet Type 02
- **Distributed Load Data** Packet Type 06
- **Node Temperature Data** Packet Type 10
- **Name Components** Packet Type 21
- **File Header** Packet Type 25

For 2D volume meshes, the elements must exist in a constant z plane.

6.3.10.2. Grouping Elements to Create Cell Zones

Elements are grouped in PATRAN using the `Named Component` command to create the multiple cell zones. All elements grouped together are placed in a single cell zone in Ansys Fluent. If the elements are not grouped, Ansys Fluent will place all the cells into a single zone.

6.3.11. Mechanical APDL Files

There are three different ways in which you can import a Mechanical APDL file into Ansys Fluent.

- You can generate a surface or volume mesh containing triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements using Mechanical APDL or ARIES, and import it into the meshing mode of Fluent using the commands described in the Fluent Meshing section of the User's Guide. Adhere to the restrictions described in Appendix B: Mesh File Format (p. 839) in the Fluent Meshing section of the User's Guide. In meshing mode, complete the mesh generation (if necessary); then you can switch to the solution mode of Fluent or read it into a new Fluent session as described in Fluent Meshing Mode Mesh Files (p. 1125).
- You can generate a Mechanical APDL volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements, as well as with higher order elements like 20 node hexahedron, SOLID92, and SOLID187. Then import it directly to Ansys Fluent using the **File/Import/Mechanical APDL** ribbon tab item, as described in Mechanical APDL Files (p. 957).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The higher order elements will be converted to their corresponding linear elements during the import in Ansys Fluent.

- You can generate a Mechanical APDL volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements, and then use the `fe2ram` filter to convert the Mechanical APDL file into the format used by Ansys Fluent. To convert an input file in ANSYS 5.4 or 5.5 format to an output file in Ansys Fluent format, follow the instructions in Using the fe2ram Filter to Convert Files (p. 1132). After the output file has been written, you can read it into Ansys Fluent using the **File/Read/Mesh...** ribbon tab item, as described in Reading Mesh Files (p. 929).

After reading a triangular or tetrahedral volume mesh using method 2 or 3 above, you should improve its quality through smoothing (as described in Quality-Based Smoothing (p. 1269)).

6.3.11.1. Recognized Ansys 5.4 and 5.5 Datasets

Ansys Fluent can import mesh files from ANSYS 5.4 and 5.5 (`.cdb` files), retaining original boundary names. The following ANSYS file datasets are recognized by the Ansys Fluent mesh import utility:

- **NBLOCK** node block data
- **EBLOCK** element block data
- **CMBLOCK** element/node grouping

The elements must be STIF63 linear shell elements. In addition, if element data without an explicit element ID is used, the filter assumes sequential numbering of the elements when creating the zones.

6.3.12. CFX Files

You can import the meshes from 3D CFX files, such as definition (`.def`) and result (`.res`) files into Ansys Fluent, using the **File/Import/CFX** ribbon tab item, as described in CFX Files (p. 954). The `fe2ram` utility is used as the import filter, which can be used as a stand-alone program to obtain an Ansys Fluent mesh file. See Using the fe2ram Filter to Convert Files (p. 1132) for information about `fe2ram`.

Important:

Note that you have the ability to import only the mesh from a CFX file, and not any results or data.

When importing a mesh from a CFX definition or results file, select whether you want the Ansys Fluent zones to be created from the physics data objects or the primitive mesh region objects. The former option is the default and is called "Zoning by CCL" and the latter option is called "Zoning by Group". This will allow you to choose the type of mesh topology you would like to preserve when importing the file:

- If you want zones to be created from the physics data objects, enable **Create Zones from CCL Physics Data** in the **Select File** dialog box.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- If you want zones to be created from the primitive mesh region objects, disable **Create Zones from CCL Physics Data** in the **Select File** dialog box. This will result in the group zoning.

  Important:

  The primitive mesh topology may contain additional regions that do not appear in the physics definition.

The default import method is the **Create Zones from CCL Physics Data** method. This method will not import CFX subdomain regions, however, the zoning by group method can import subdomain regions.

The 3D element set corresponding to zones/domains present in these files are imported as cell zones in Ansys Fluent. They may contain tetrahedral, pyramidal, wedge, and hexahedral elements. The boundary zones in these files are a group of faces with a boundary condition name/type and are imported as face zones with the boundary condition name/type retained in Ansys Fluent. The following boundary condition types are retained:

- **inlet**
- **outlet**
- **symmetry**
- **interface**
- **wall**

The boundaries of type `Interface` may be conformal or non-conformal. If they are non-conformal, they are retained. However, conformal interfaces contain coincident nodes that are merged and changed to type `Interior`. For some cases, for the merge to work correctly, the merge tolerance may need to be adjusted. Alternatively, the Fuse Face Zones Dialog Box (p. 5427) in Ansys Fluent can be used to merge the conformal interfaces. For details, see Fusing Face Zones (p. 1244).

6.3.13. Using the fe2ram Filter to Convert Files

The `fe2ram` filter can be used to manually convert files of certain formats into Ansys Fluent mesh files, which can then be read into Ansys Fluent. To use the `fe2ram` filter, enter the following at a command prompt in a terminal or command window:

`utility fe2ram` [*dimension*] *format* [*zoning*] *input_file output_file*

Note:

The items enclosed in square brackets are optional. Do not type the square brackets.

- *dimension* indicates the dimension of the dataset. Replace *dimension* with `-d2` to indicate that the mesh is two dimensional. For a 3D mesh, do not enter any value for *dimension*, because 3D is the default.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- *format* indicates the format of the file you want to convert. For example, replace *format* with `-tANSYS` for a Mechanical APDL file, `-tIDEAS` for an I-deas file, `-tNASTRAN` for a NASTRAN file, and so on. To print a list of the formats which `fe2ram` can convert, type

  `utility fe2ram -cl -help`.

  Note:

  fe2ram does not support VRML 2.0 or later.

- *zoning* indicates how zones were identified in the original format. Replace *zoning* by `-zID` for a mesh that was zoned by property IDs, or `-zNONE` to ignore all zone groupings. For a mesh zoned by group, do not enter anything for *zoning*, because zoning by groups is the default.

- *input_file* is the name of the original file. *output_file* is the name of the file to which you want to write the converted mesh information. Note that the *output_file* cannot be a CFF file (`.msh.h5`).

  For example, if you wanted to convert the 2D I-deas volume mesh file `sample.unv` to an output file called `sample.msh`, you will enter the following command:

  ```
  utility fe2ram -d2 -tIDEAS sample.unv sample.msh
  ```

6.3.14. Removing Hanging Nodes / Edges

As noted in Mesh Topologies (p. 1103), while Ansys Fluent can accept meshes that contain hanging nodes or hanging edges, in 3D cases by default the adjacent cells are automatically converted to polyhedra when read to remove such hanging nodes / edges. Each cell that is converted will retain the same overall dimensions, but the number of faces associated with the cell may increase. You can opt to disable this conversion by using the following text command prior to reading: `file/convert-hanging-nodes-during-read? no`. Note that when the conversion is disabled, the creation of interior walls can yield an error if hanging nodes / edges are located on the zone that is turned into an interior wall. This problem can occur in the following cases:

- If you read a mesh file that has an interior (or two-sided) wall boundary condition setup, but the shadow wall has not been created yet.

- If you turn an interior surface into a wall.

- If you slit an interior surface (for example, turn it into a non-conformal interface).

Such error-producing hanging nodes / edges may be present in hexcore or CutCell meshes, for example. If you find you need to remove the hanging nodes / edges after reading, you can convert the associated cells to polyhedra by using the `mesh/polyhedra/convert-hanging-nodes` text command.

6.3.14.1. Limitations

Meshes with polyhedra have the following limitations:

- The following mesh manipulation tools are not available on polyhedral meshes:

  – `extrude-face-zone` under the `modify-zone` option

  - skewness smoothing
  - swapping (will not affect polyhedral cells)

- The polyhedral cells that result from the conversion are not eligible for adaption with the hanging node method, though they can be refined with the default polyhedral unstructured mesh adaption (PUMA) method. For more information about adaption, see Adapting the Mesh (p. 3755).
- Note the following with regard to the polyhedral cells that result from this conversion and the update methods available for dynamic mesh problems:
  - None of the remeshing methods will modify polyhedral cells.
  - Smoothing is allowed for polyhedral cells, and radial basis function smoothing is the recommended method (see Radial Basis Function Smoothing (p. 1798) for details). The linearly elastic solid smoothing method is not compatible with polyhedral cells.

6.3.15. Fluent/UNS and RAMPANT Case Files

If you have a Fluent/UNS 3 or 4 case file or a RAMPANT 2, 3, or 4 case file and you want to run an Ansys Fluent simulation using the same mesh, you can read it into Ansys Fluent using the **File/Read/Case...** ribbon tab item, as described in Reading Fluent/UNS and RAMPANT Case and Data Files (p. 939).

6.3.16. FLUENT 4 Case Files

If you have a FLUENT 4 case file and you want to run an Ansys Fluent simulation using the same mesh, import it into Ansys Fluent using the **File/Import/FLUENT 4 Case File...** ribbon tab item. Ansys Fluent will read mesh information and zone types from the FLUENT 4 case file.

Important:

FLUENT 4 may interpret some pressure boundaries differently from the current release of Ansys Fluent. Check the conversion information printed out by Ansys Fluent to see if you need to modify any boundary types.

To manually convert an input file in FLUENT 4 format to an output file in the legacy Ansys Fluent format, enter the following command:

`utility fl42seg` *input_filename output_filename*

After the output file has been written, you can read it into Ansys Fluent using the **File/Read/Case...** ribbon tab item, as described in Reading Mesh Files (p. 929).

6.3.17. Ansys FIDAP Neutral Files

If you have an Ansys FIDAP Neutral file and you want to run an Ansys Fluent simulation using the same mesh, import it using the ribbon item. Ansys Fluent will read mesh information and zone types from the Ansys FIDAP file.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can manually convert an input file in Ansys FIDAP format to an output file in Ansys Fluent (as described in detail in Using the fe2ram Filter to Convert Files (p. 1132)):

`utility fe2ram [` *dimension* `] -tFIDAP7` *input_file output_file*

The item in square brackets is optional. Do not type the square brackets. For a 2D file, replace *dimension* with `-d2`. For a 3D file, do not enter anything for *dimension*, because 3D is the default.

After the output file has been written, read it into Ansys Fluent using the **File/Read/Case...** ribbon tab item, as described in Reading Mesh Files (p. 929).

6.3.18. Reading Multiple Mesh/Case/Data Files

There may be some cases in which you will need to read multiple mesh files (subdomains) to form your computational domain.

- To solve on a multiblock mesh, generate each block of the mesh in the mesh generator and save it to a separate mesh file.
- For very complicated geometries, it may be more efficient to save the mesh for each part as a separate mesh file.

The mesh node locations need not be identical at the boundaries where two separate meshes meet. Ansys Fluent can handle non-conformal mesh interfaces. See Non-Conformal Meshes (p. 1149) for details about non-conformal mesh boundaries.

There are three ways of reading multiple mesh files in Ansys Fluent:

- Read multiple mesh files into the solution mode of Fluent.
- Read multiple mesh files into the meshing mode of Fluent.
- Use `tmerge` to manipulate the individual files and merge them into a single file that can then be read into Fluent. Note that CFF files (`.msh.h5`) are not supported with `tmerge`.

Note:

If your multiple meshes are not properly scaled, located, and/or oriented relative to each other, you have the ability to manipulate the cell zones in the solution mode of Ansys Fluent, as described in Scaling Individual Cell Zones (p. 1265), Translating Individual Cell Zones (p. 1266), and Rotating Individual Cell Zones (p. 1267).

6.3.18.1. Reading Multiple Mesh Files via the Solution Mode of Fluent

The solution mode of Fluent allows you to handle more than one mesh at a time within the same solver settings. This capability of handling multiple meshes saves time, since you can directly read in the different mesh files and start setting up the solution, without having to switch over from meshing mode or employ another tool such as `tmerge`.

The steps to take when reading more than one mesh file are:

1. Read in your first mesh file.

File → **Read** → **Mesh...**

In the **Select File** dialog box, select the mesh file and click **OK**.

2. Read in your second mesh file and append it to the first mesh selected in the first step.

Domain → **Zones** → **Append** → **Append Case File...**

In The Select File Dialog Box (p. 907), select the second mesh file and click **OK**.

3. (optional). Display your meshes using the **Mesh Display** dialog box.

Setup → **General** → **Display...**

You will find that the second mesh is appended to the first.

Ansys Fluent also allows you to append the data on the mesh. To do that, follow the procedure above. For the second step, use the following ribbon tab item:

Domain → **Zones** → **Append** → **Append Case & Data Files...**

Select the case file in the **Select File** dialog box, and click **OK**. Both the case and data files will be appended.

Important:

Review your case setup after appending multiple mesh and/or data files before proceeding with the calculation.

6.3.18.2. Reading Multiple Mesh Files via the Meshing Mode of Fluent

1. Generate the mesh for the whole domain in the mesh generator, and save each cell zone (or block or part) to a separate mesh file for Fluent.

Important:

If one (or more) of the meshes you want to import is structured (for example, a FLUENT 4 mesh file), first convert it to Ansys Fluent format using the `fl42seg` filter described in FLUENT 4 Case Files (p. 1134).

2. In the meshing mode of Fluent, combine the meshes into one mesh file.

   a. Read all of the mesh files. As the mesh files are read, they will be automatically merged into a single mesh.

   b. Save the merged mesh file.

   See the Fluent Meshing section of the User's Guide for information about reading and writing files in meshing mode.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Switch over to the solution mode of Fluent or read the combined mesh file into a new session using the **File/Read/Mesh...** ribbon tab item.

For a conformal mesh, if you do not want a boundary between the adjacent cell zones, use the **Fuse Face Zones** dialog box to fuse the overlapping boundaries. For details, see Fusing Face Zones (p. 1244). The matching faces will be moved to a new zone with a boundary type of **interior** and the original zone(s) will be discarded.

Important:

If you are planning to use sliding meshes, or if you have non-conformal boundaries between adjacent cell zones, do not combine the overlapping zones. Instead, change the boundary zone type as needed and continue the setup described in Non-Conformal Meshes (p. 1149).

6.3.18.3. Reading Multiple Mesh Files via tmerge

1. Generate the mesh for the whole domain in the mesh generator, and save each cell zone (or block or part) to a separate legacy mesh file (`.msh`) for Ansys Fluent.

   Important:

   If one (or more) of the meshes you want to import is structured (for example, a FLUENT 4 mesh file), first convert it to Ansys Fluent format using the `fl42seg` filter described in FLUENT 4 Case Files (p. 1134).

2. Before launching Fluent, use the `tmerge` filter to combine the meshes into one mesh file. The `tmerge` method allows you to rotate, scale, and/or translate the meshes before they are merged. Note that the `tmerge` filter allows you to merge large meshes with very low memory requirement.

   a. For 3D problems, type `utility tmerge -3d`. For 2D problems, type `utility tmerge -2d`.

   b. When prompted, specify the names of the input files (the separate mesh files) and the name of the output file in which to save the complete mesh. Be sure to include the `.msh` extension.

   c. For each input file, specify scaling factors, translation distances, and rotation information.

   For information about the various options available when using `tmerge`, type `utility tmerge -h`.

3. Read the combined mesh file into the solution mode of Fluent in the usual manner (using the **File/Read/Mesh...** ribbon tab item).

For a conformal mesh, if you do not want a boundary between the adjacent cell zones, use the **Fuse Face Zones** dialog box to fuse the overlapping boundaries. For details, see Fusing Face

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Zones (p. 1244). The matching faces will be moved to a new zone with a boundary type of **interior** and the original zone(s) will be discarded.

Important:

If you are planning to use sliding meshes, or if you have non-conformal boundaries between adjacent cell zones, do not combine the overlapping zones. Instead, change the boundary zone type as needed and continue the setup described in Non-Conformal Meshes (p. 1149).

In this example, scaling, translation, or rotation is not requested. Hence you can simplify the inputs to the following:

```
 user@mymachine:> utility tmerge -2d

Starting /ansys_inc/v241/fluent/fluent24.1.0/utility/tmerge/lnamd64/tmerge_2d

 Append 2D grid files.
 tmerge2D ANSYS Inc, stream

 Enter name of grid file (ENTER to continue) :  my1.msh

 x,y scaling factor, eg. 1 1          : 1 1

 x,y translation, eg. 0 1             : 0 0

 rotation angle (deg), eg. 45         : 0

 Enter name of grid file (ENTER to continue) :  my2.msh

 x,y scaling factor, eg. 1 1          : 1 1

 x,y translation, eg. 0 1             : 0 0

rotation angle (deg), eg. 45          : 0

 Enter name of grid file (ENTER to continue) :  {Enter}

 Enter name of output file            : final.msh

6.3.19. Reading Surface Mesh Files

Surface meshes are used as background meshes for geometry-based adaption. Perform the following steps to read the surface mesh file into Ansys Fluent:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Open the **Surface Meshes** dialog box (Figure 6.24: The Surface Meshes Dialog Box (p. 1139)). How you open this dialog box depends on the adaption method you plan to use:

   - If you are using the PUMA adaption method (the default for 3D), open the **Auxiliary Geometry Definition** dialog box (as described in Managing Auxiliary Geometry Definitions (p. 1759)), select **Surface Mesh** from the **Type** drop-down list, and then click the **Surfaces Meshes...** button.

   - If you are using the hanging node adaption method, open the **Geometry Based Adaption** dialog box (as described in Performing Geometry-Based Adaption with the Hanging Node Method (p. 3791)), enable the **Reconstruct Geometry** option, and then click the **Surfaces Meshes...** button.

2. In the Surface Meshes Dialog Box (p. 5566), click **Read...** and select the surface mesh file using The Select File Dialog Box (p. 907).

   Specify the units the mesh was created in (default is meters).

   Figure 6.24: The Surface Meshes Dialog Box

   
   Note that you can also display and delete the surfaces using Figure 6.24: The Surface Meshes Dialog Box (p. 1139).

3. Continue performing the adaption:

   - If you are using the PUMA adaption method (the default for 3D), enable the **Reconstruct Geometry** option in the **General Adaption Controls** dialog box, set up the geometry-based adaption using the **Manage Geometry-Based Adaption** dialog box, and perform adaption as described in Refining and Coarsening (p. 3759).

   - If you are using the hanging node adaption method, make a selection from the **Wall Zones** list in the **Geometry Based Adaption** dialog box, click **Set...**, set up the adaption in the Geometry Based Adaption Controls Dialog Box (p. 5434) that opens (as described in Performing Geometry-Based Adaption with the Hanging Node Method (p. 3791)), and perform adaption as described in Refining and Coarsening (p. 3759).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.4. Reference Frames

You can create multiple local reference frames for use in setting up Ansys Fluent cases.

The reference frames feature allows you to create local coordinate systems with a given position and orientation, either with or without motion. Without local reference frames, you would have to specify things such as surfaces based on the global reference frame/coordinate system.

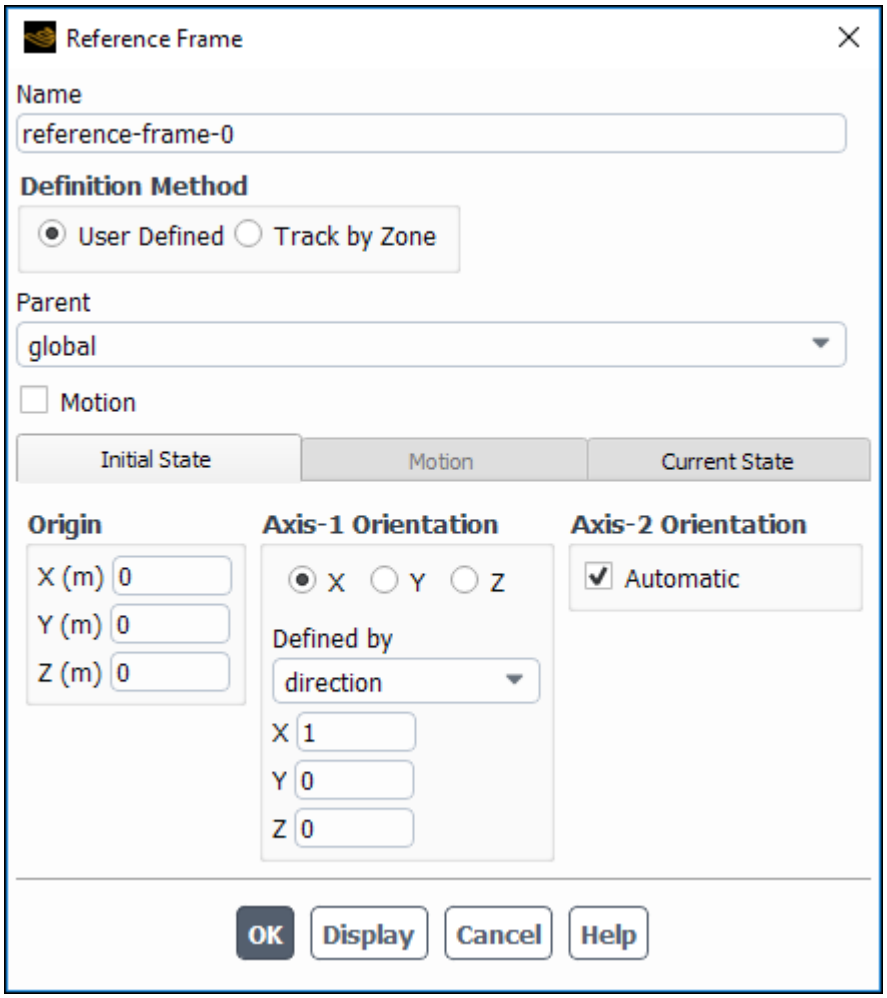
6.4.1. Creating and Using Reference Frames

To create a reference frame:

1. Open the **Reference Frame** dialog box by right-clicking **Reference Frames** in the outline view and selecting **New...**.

   Setup → Reference Frames → New...

   Figure 6.25: The Reference Frame Dialog Box



2. Enter a **Name** for the reference frame.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Specify how you want to define the reference frame.

   - **User Defined** allows you to completely specify the details of where the reference frame is located and oriented and how it moves.

   - **Track by Zone** allows you to "attach" a reference frame to a cell zone. You can still specify where the reference frame is located and how it is oriented, but you cannot specify any motion. If the zone it is tracking moves, so does the reference frame.

4. Specify either the **Parent** reference frame (when you select **User Defined**) or the **Zone** that the reference frame will track (when you select **Track by Zone**).

5. (Optional, **User Defined** only) enable **Motion** and specify the additional settings that appear in the **Motion** tab.

   Figure 6.26: The Motion Tab of the Reference Frame Dialog Box

   - **Linear Velocity** is the linear velocity with respect to the parent reference frame orientation.

   - **Rotational Velocity** is the rotational velocity with respect to the parent reference frame orientation.

6. Specify the **Origin** of your reference frame.

7. Specify the orientation of the first axis of your reference frame in the **Axis-1 Orientation** group box. Select which axis you are specifying using by selecting either **X**, **Y**, or **Z**. *You can either specify the orientation by providing a point or a direction.*

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8. (Optional) Specify the orientation of the second axis of your reference frame. By default, Fluent automatically provides an orientation for the second axis, but you can specify it manually by disabling **Automatic** and providing your own inputs.

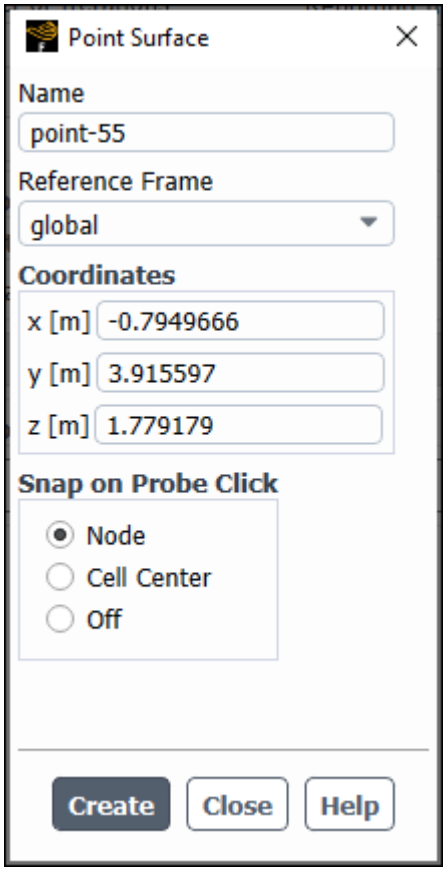
9. Click **OK** to create the reference frame.

The **Current State** field shows you the current origin and axes directions of the reference frame with respect to the global reference frame.

Using Reference Frames

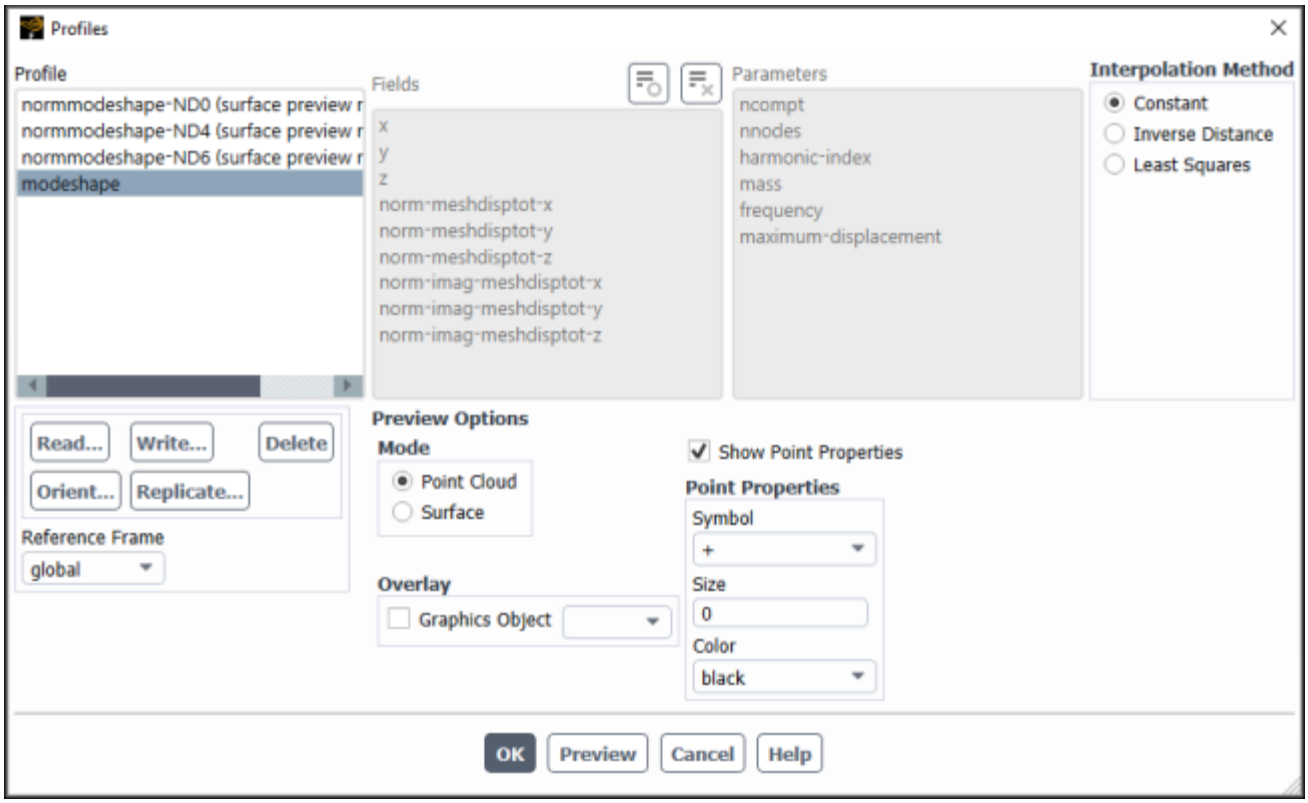
You can use any local reference frame when defining point surfaces and profiles. Just select the desired reference frame from the **Reference Frame** drop-down in the **Point Surface** or **Profile** dialog boxes.

Figure 6.27: Point Surface Creation on Local Reference Frame



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.28: Profile Definition on Local Reference Frame



6.5. Curvilinear Coordinate Systems

You can create multiple Curvilinear Coordinate Systems (CCS) for use in setting up Ansys Fluent cases.

The CCS feature allows you to create local coordinate systems that follow the geometry of the model. For example, you can create a CCS where one of the directions follow the curved shaped of a motor winding. This is especially useful for defining anisotropic thermal conductivity, as described in Anisotropic Thermal Conductivity with Curvilinear Coordinate System (CCS) (p. 2154).

6.5.1. Defining a Curvilinear Coordinate System

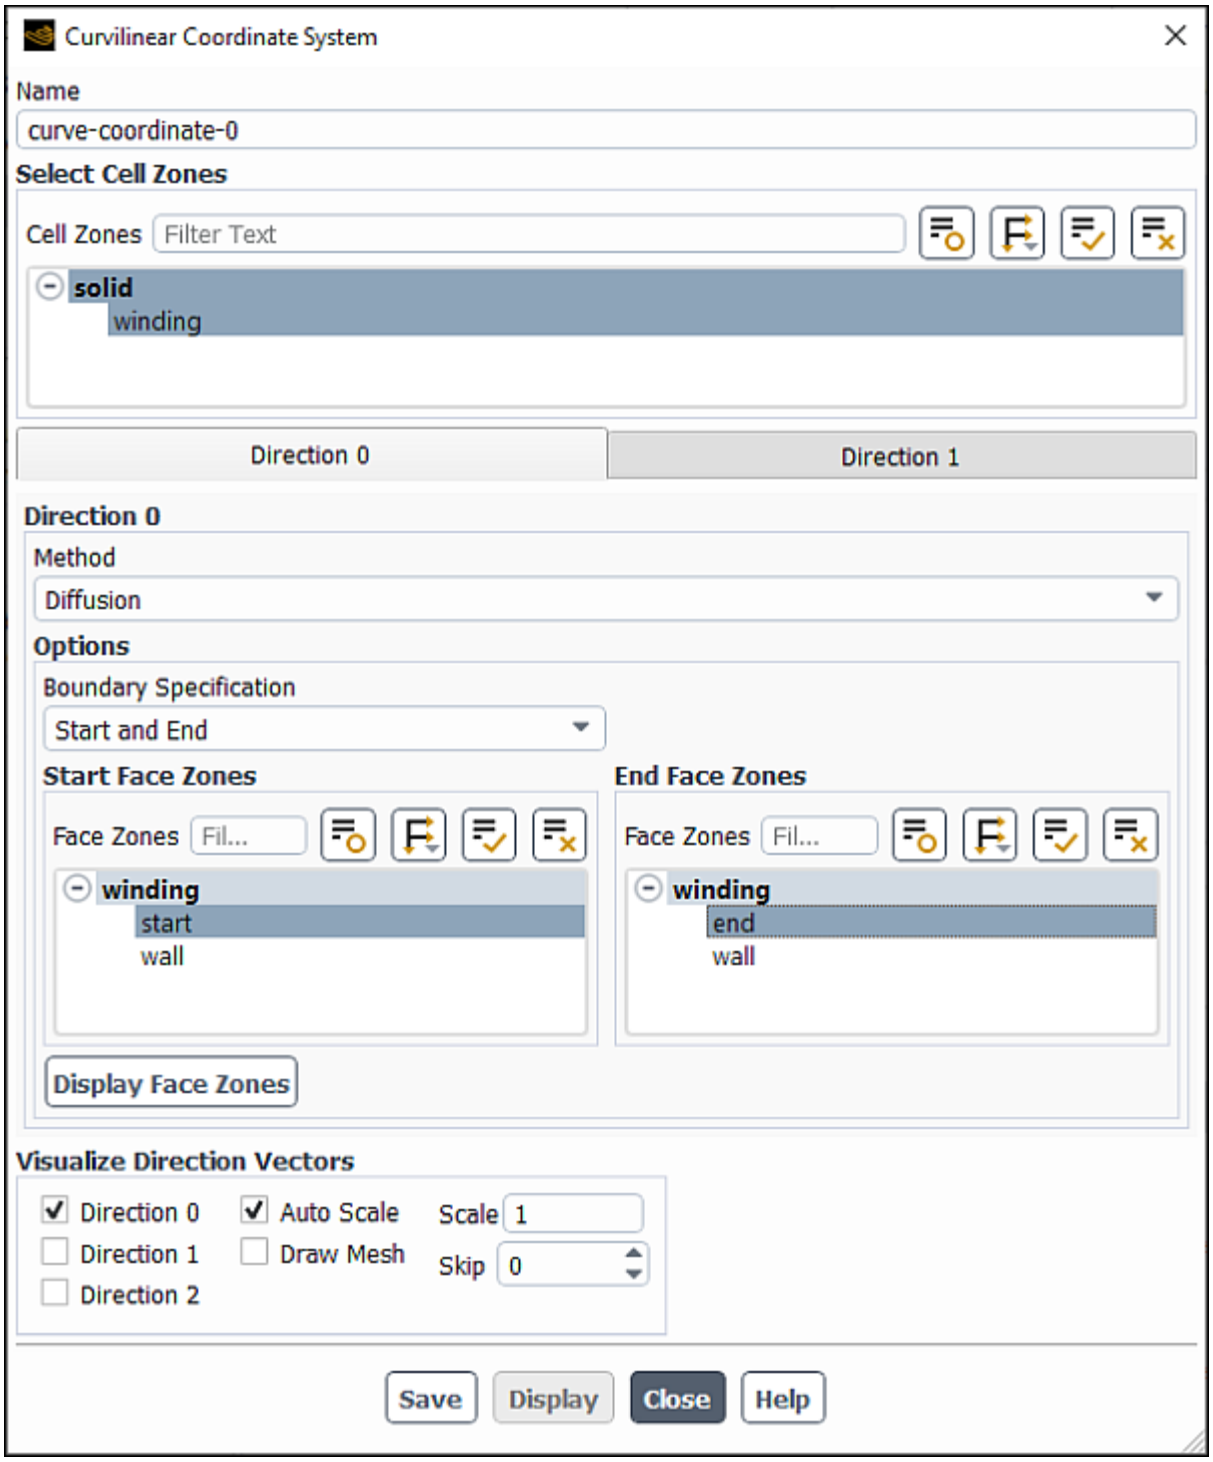
Define a CCS using the following steps:

1. Open the **Curvilinear Coordinate System** dialog box.

   Setup → **Curvilinear Coordinate System** **New...**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.29: The Curvilinear Coordinate System Dialog Box



2. Under **Name**, enter a name for the CCS.
3. Under **Select Cell Zones**, select the cell zones for which you want to define the CCS.
4. Define directions for the CCS. **Direction 0** and **Direction 1** must be specified. Direction 2 is computed automatically using the cross product of Direction 0 and 1.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. For **Direction 0** and **Direction 1**, you must specify the direction using the geometry in the chosen cell zone.

   Under **Method**, choose one of the following options:

   - `Diffusion` - The direction of the vector field is specified with **Start and End** face zones. If the geometry is a closed loop, you can use the **Jump** boundary by specifying a coupled wall as a cross section though the loop, which is then split into start and end faces.
   - `Base Vector` - You have the option of specifying user defined vectors if you know one of the directions is aligned with the global coordinate system over the entire geometry.
   - `Vector Projection` (available only for **Direction 1**) - Requires the specification of the **X**, **Y**, and **Z** components of an **Alignment Vector**. The direction of the vector field is defined by the projection of the alignment vector onto the principal vector field (**Direction 0**).

   Important:

   The accuracy of the Vector Projection method is dependent on the specified Alignment Vector and principal vector (Direction 0), therefore it is highly recommended that you visualize and verify the computed vectors when using the Vector Projection method. For example on the importance of visualizing the vector fields, see Curvilinear Coordinate System Example (p. 1146).

6. Under **Visualize Direction Vectors**, there are various options to affect how the CCS is displayed in the graphics window.

   - **Direction 0** - Selects Direction 0 to display in the graphics viewer.
   - **Direction 1** - Selects Direction 1 to display in the graphics viewer.
   - **Direction 2** - Selects Direction 2 to display in the graphics viewer.
   - **Auto Scale** - Scales the vectors to an appropriate size.
   - **Draw Mesh** - Opens the Mesh Display dialog box.
   - **Scale** - Specifies the size of the vectors for display.
   - **Skip** - Thins the number of vectors displayed to improve visibility.

7. Click **Display** to visualize the direction vectors.

   Note:

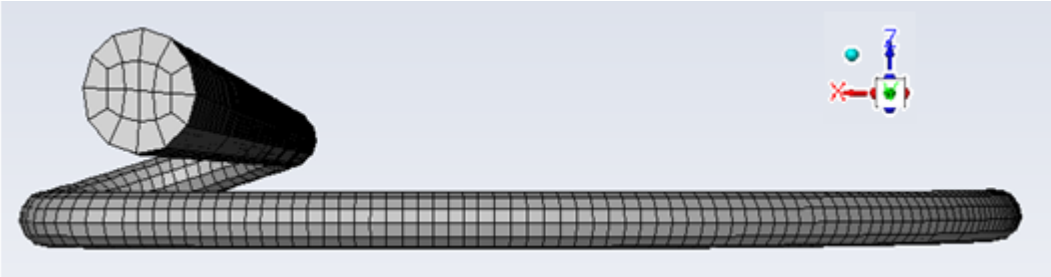
   Direction vectors are not displayed on all interior boundaries.

8. Click **Save** to save the coordinate system.

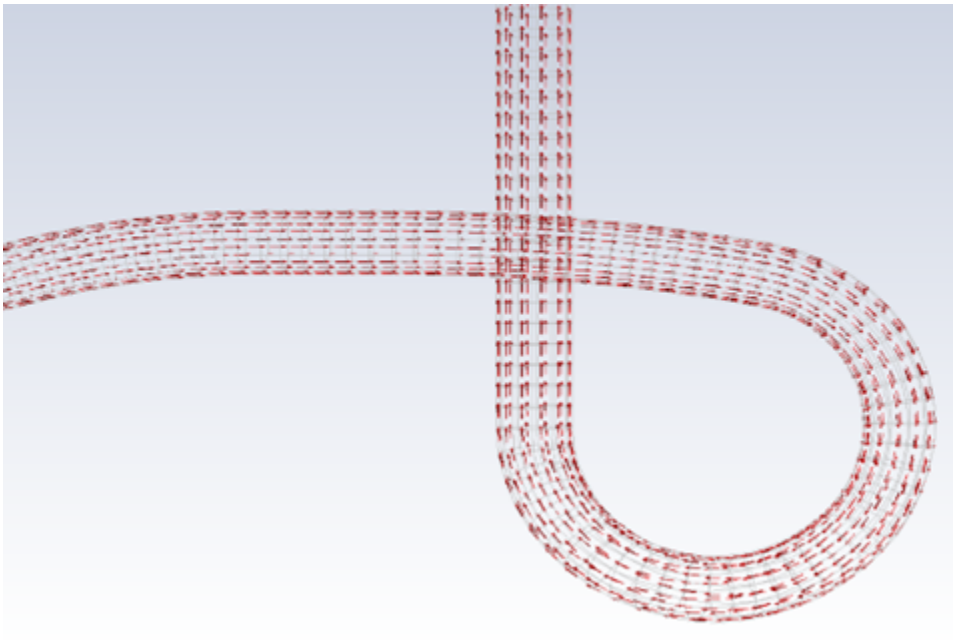
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.5.2. Curvilinear Coordinate System Example

Consider creating a curvilinear coordinate system that follows this coil geometry:

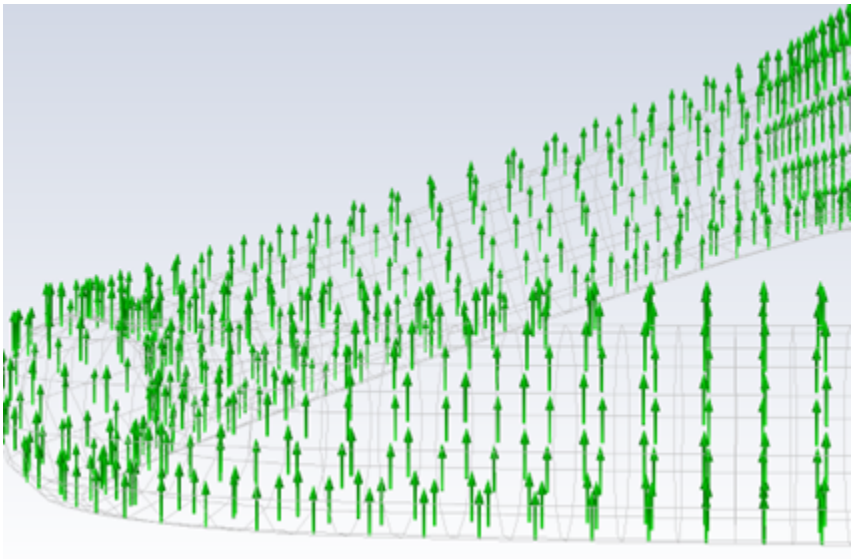


- For **Direction 0**, the `Diffusion` method can be used with the circular end faces being used as the Start Face Zone and End Face Zone. The result for Direction 0 is a vector field that follows the lengthwise curvature of the coil.

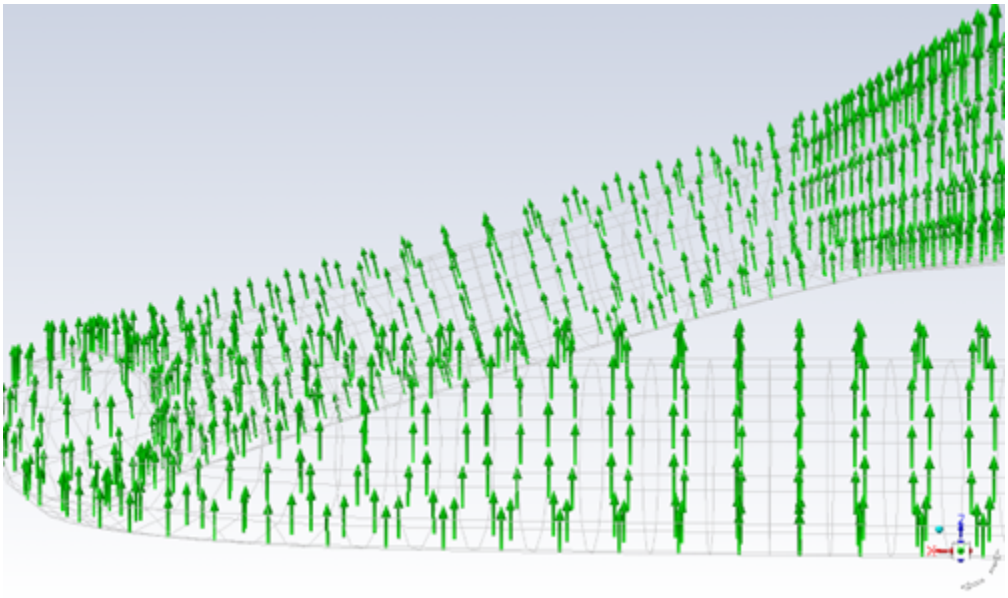


- For **Direction 1**, the `Diffusion` method cannot be used because there is only a cylindrical face (no start or end face exists). If the `Base Vector` method was used with the direction vector in +Z direction (0,0,1), Direction 1 would still not be aligned with curvature of coil.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- For **Direction 1**, the `Vector Projection` method should be used to align the secondary direction with the curvature of the coil. Specifying the **Alignment Vector** in the +Z direction (0,0,1) ensures that the vector field for Direction 1 is normal to Direction 0.



6.5.3. Limitations of Curvilinear Coordinate Systems

The following limitations exist for Curvilinear Coordinate Systems:

- Periodic Boundary face zones are not available in the Face Zone lists for selection of Start, End Jump condition faces.

6.5.4. Limitations with Jump Boundary

1. Jump boundaries are valid for closed-loop geometries only.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

An open ended geometry with jump boundary will lead to incorrect results. See below for an example of an open-ended geometry. Left and right sides are open, and jump is provided on a coupled wall in between two cell zones C1 and C2.

2. Closed loops cannot have more than one jump boundary.

   In the example below, there are four cell zones CZ1, CZ2, CZ3 and CZ4, and 4 coupled walls CW1, CW2, CW3 and CW4. You can only specify one coupled wall inside the closed loop geometry as the jump boundary (CW4 in this case).

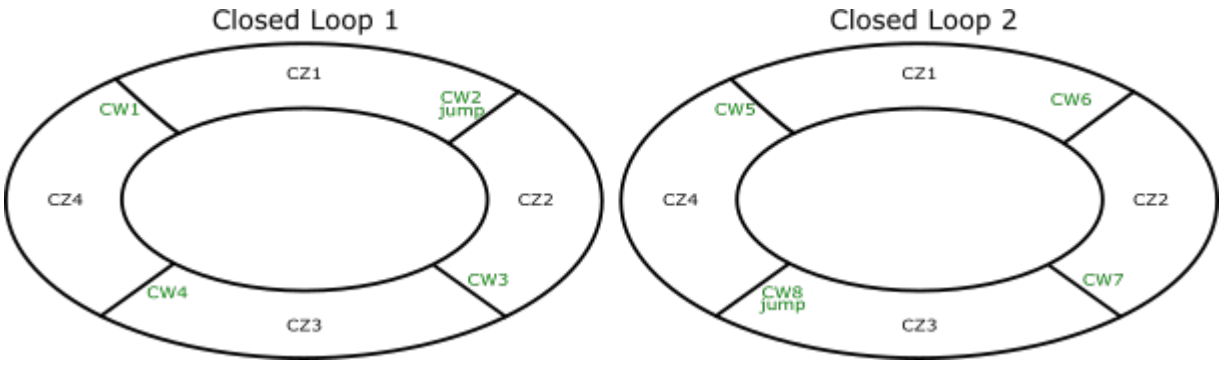
   Using the same example, you cannot have all coupled walls with same thread ID. In such a scenario, specifying a jump boundary on one of the coupled walls would result in all four coupled walls having a jump boundary, invalidating the condition of only one jump per closed loop.

3. Considerations for multiple closed loops

   Multiple closed loops with the same thread ID for coupled walls can work only if one coupled wall is selected as the jump boundary (CW2 in example below). Only one of CW1, CW2, CW3 or CW4 can be selected in this case. Otherwise, there would be more than one jump boundary in each closed loop.

   If different closed loop geometries have different coupled wall thread IDs, then you can select one of the coupled walls in each loop as the jump boundary (CW2 and CW8 in example below).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



6.6. Non-Conformal Meshes

In Ansys Fluent it is possible to use a mesh that has non-conformal interfaces, that is, boundaries between cell zones that connect to each other in which the mesh node locations are not identical. Such non-conformal interfaces permit the cell zones to pass fluxes from one mesh to another.

6.6.1. Non-Conformal Mesh Calculations

6.6.2. Non-Conformal Interface Algorithm

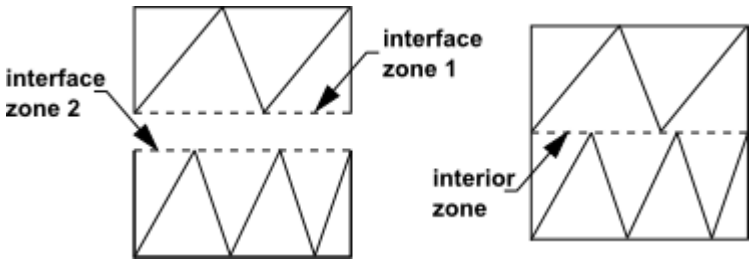
6.6.3. Requirements and Limitations of Non-Conformal Meshes

6.6.4. Using a Non-Conformal Mesh in Ansys Fluent

6.6.1. Non-Conformal Mesh Calculations

To compute the flux across the non-conformal boundary, Ansys Fluent must first compute the intersection between the interface zones that make up the boundary. In the case of a solid-to-solid zone interface of the same material or a fluid-to-fluid zone interface, the resulting intersection produces an interior zone where the two interface zones overlap (see Figure 6.30: Completely Overlapping Mesh Interface Intersection (p. 1149)). In the case of a solid-to-solid zone interface of different materials or a fluid-to-solid zone interface, the boundary is treated as a coupled wall (see The Coupled Wall Option (p. 1155)).

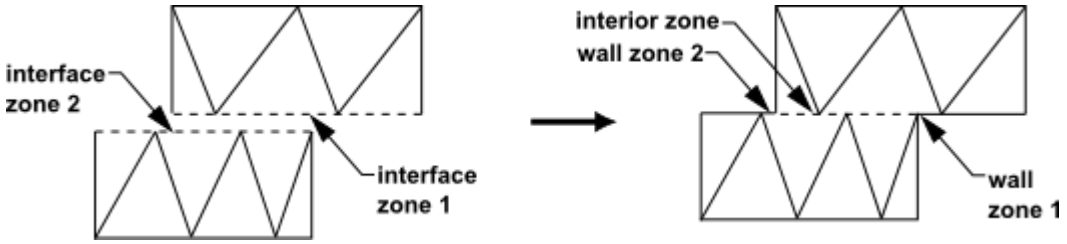
Figure 6.30: Completely Overlapping Mesh Interface Intersection



If one of the interface zones extends beyond the other (Figure 6.31: Partially Overlapping Mesh Interface Intersection (p. 1150)), by default Ansys Fluent will create additional boundary zones for the portion(s) of the boundary where the two interface zones do not overlap; these are referred to as "non-overlapping zones", and you can change their settings and/or zone type at your discretion.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

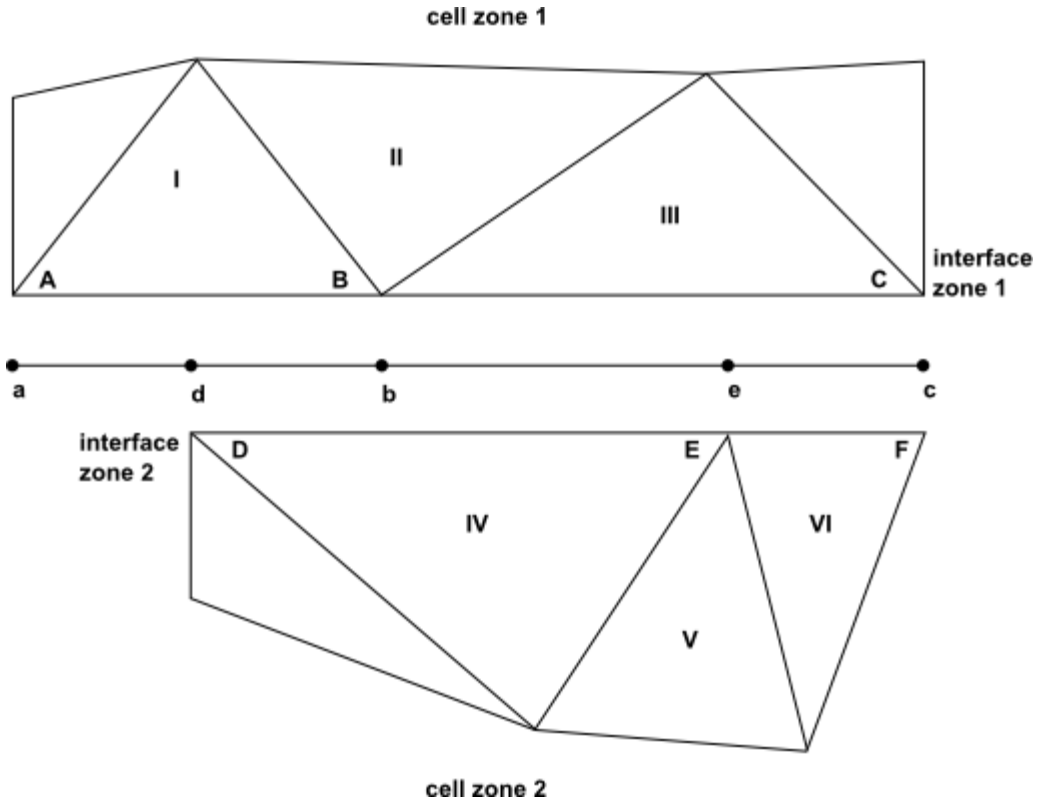
Figure 6.31: Partially Overlapping Mesh Interface Intersection



Fluxes across the mesh interface are computed using the faces resulting from the intersection of the two interface zones, not from the interface zone faces.

In the example shown in Figure 6.32: Two-Dimensional Non-Conformal Mesh Interface (p. 1150), the interface zones are composed of faces A-B and B-C, and faces D-E and E-F.

Figure 6.32: Two-Dimensional Non-Conformal Mesh Interface



The intersection of these zones produces the faces a-d, d-b, b-e, and e-c. Faces produced in the region where the two cell zones overlap (d-b, b-e, and e-c) are grouped to form an interior or coupled wall zone (depending on the types of the adjacent cell zones), while the remaining face (a-d) forms a wall zone.

To compute the flux across the interface into cell IV, face D-E is ignored and instead faces d-b and b-e are used to bring information into cell IV from cells I and III.

While the previous discussion described the default treatment of a non-conformal interface, there are several options you can enable at the interface in order to revise the treatment of the fluxes and/or reduce the memory usage and processing time:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- periodic boundary condition
- periodic repeats
- coupled wall
- matching
- mapped
- static

Note:

Only the coupled wall option is available for mesh interfaces created using the default one-to-one interface creation method.

These non-conformal interface options are described in the following sections.

6.6.1.1. The Periodic Boundary Condition Option
6.6.1.2. The Periodic Repeats Option
6.6.1.3. The Coupled Wall Option
6.6.1.4. Matching Option
6.6.1.5. The Mapped Option
6.6.1.6. The Static Option
6.6.1.7. Interface Zones Automatic Naming Conventions

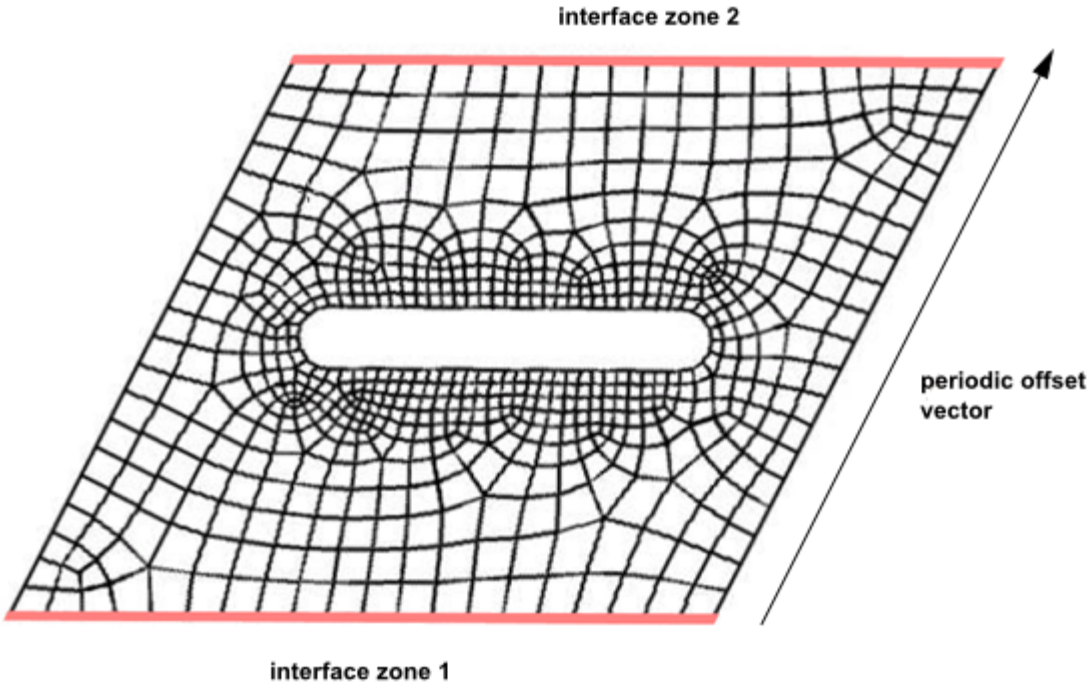
6.6.1.1. The Periodic Boundary Condition Option

Non-conformal interfaces can be used to implement a periodic boundary condition like that described for conformal periodic boundaries (see Periodic Boundary Conditions (p. 1477)). The advantage of using a mesh interface is that, unlike the standard periodic boundary condition, the nodes of the two zones do not have to match one-for-one.

The interface zones that utilize the periodic boundary condition option (Figure 6.33: Non-Conformal Periodic Boundary Condition (Translational) (p. 1152) and Figure 6.34: Non-Conformal Periodic Boundary Condition (Rotational) (p. 1153)) are coupled in the manner described in the previous section, except that the zones do not overlap (that is, the zones are not spatially coincident at any point). In order to generate the new faces that will be used to compute the fluxes across the interface, the nodes of the first zone are either translated or rotated (about a given axis) onto the other zone. The distance/angle that the nodes are translated/rotated is called the "periodic offset". The new faces will be defined between all of the combined nodes, and then applied to each of the original zones.

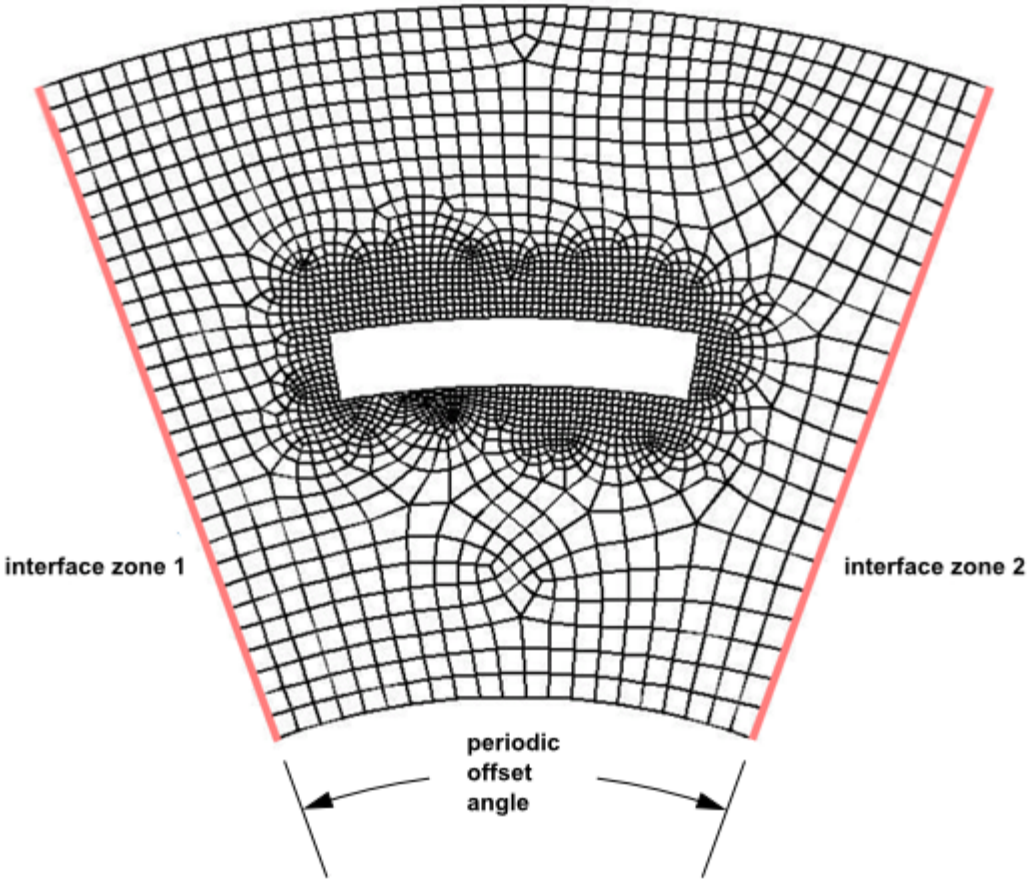
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.33: Non-Conformal Periodic Boundary Condition (Translational)



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.34: Non-Conformal Periodic Boundary Condition (Rotational)



Note:

The **Matching** option is enabled by default with the **Periodic Boundary Condition** option.

6.6.1.2. The Periodic Repeats Option

The periodic repeats option is appropriate when each of the interface zones is adjacent to a non-conformal periodic interface or a pair of conformal periodic zones (see Figure 6.35: Translational Non-Conformal Interface with the Periodic Repeats Option (p. 1154) and Figure 6.36: Rotational Non-Conformal Interface with the Periodic Repeats Option (p. 1155)). The periodic repeats option takes into account the repeating nature of the flow solutions in the two cell zones in the following manner. Wherever the interface zones overlap (that is, wherever interface zone 1 and 2 are spatially coincident), the fluxes on either side of the interface are coupled in the usual way. The portion of interface zone 1 that does not overlap is coupled to the non-overlapping portion of interface zone 2, by translating or rotating the fluxes by the periodic offset. This is similar to the treatment of non-

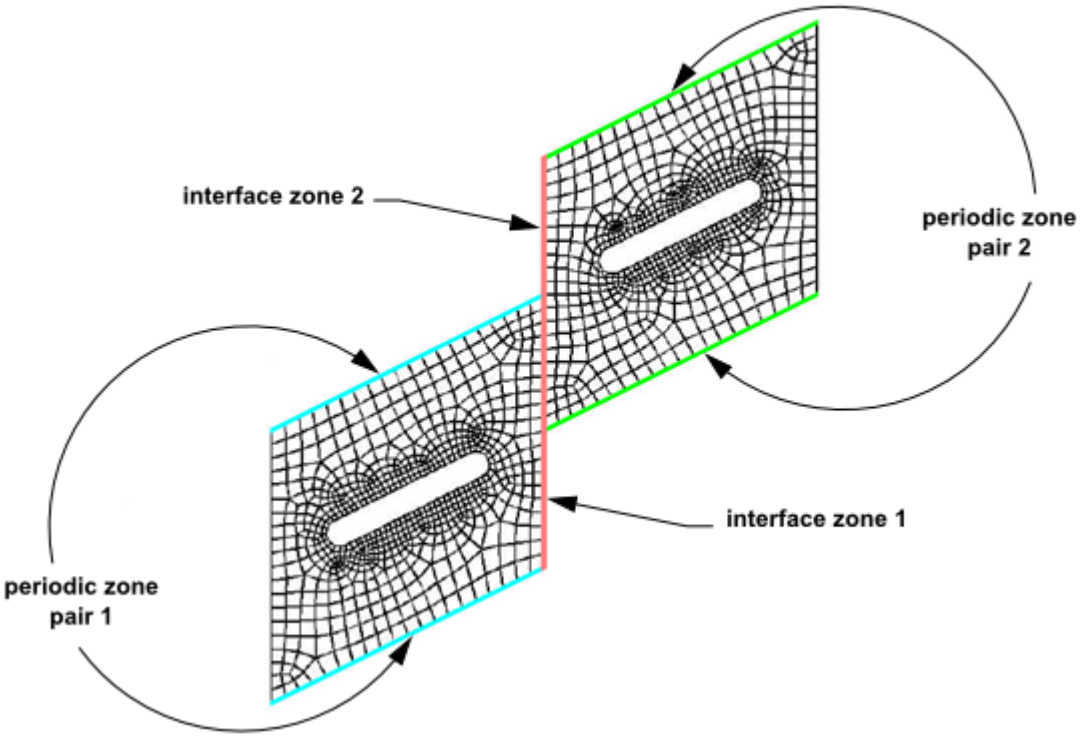
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

conformal periodic boundary conditions. The periodic repeats option is typically used in conjunction with the sliding mesh model when simulating the interface between a rotor and stator.

Note:

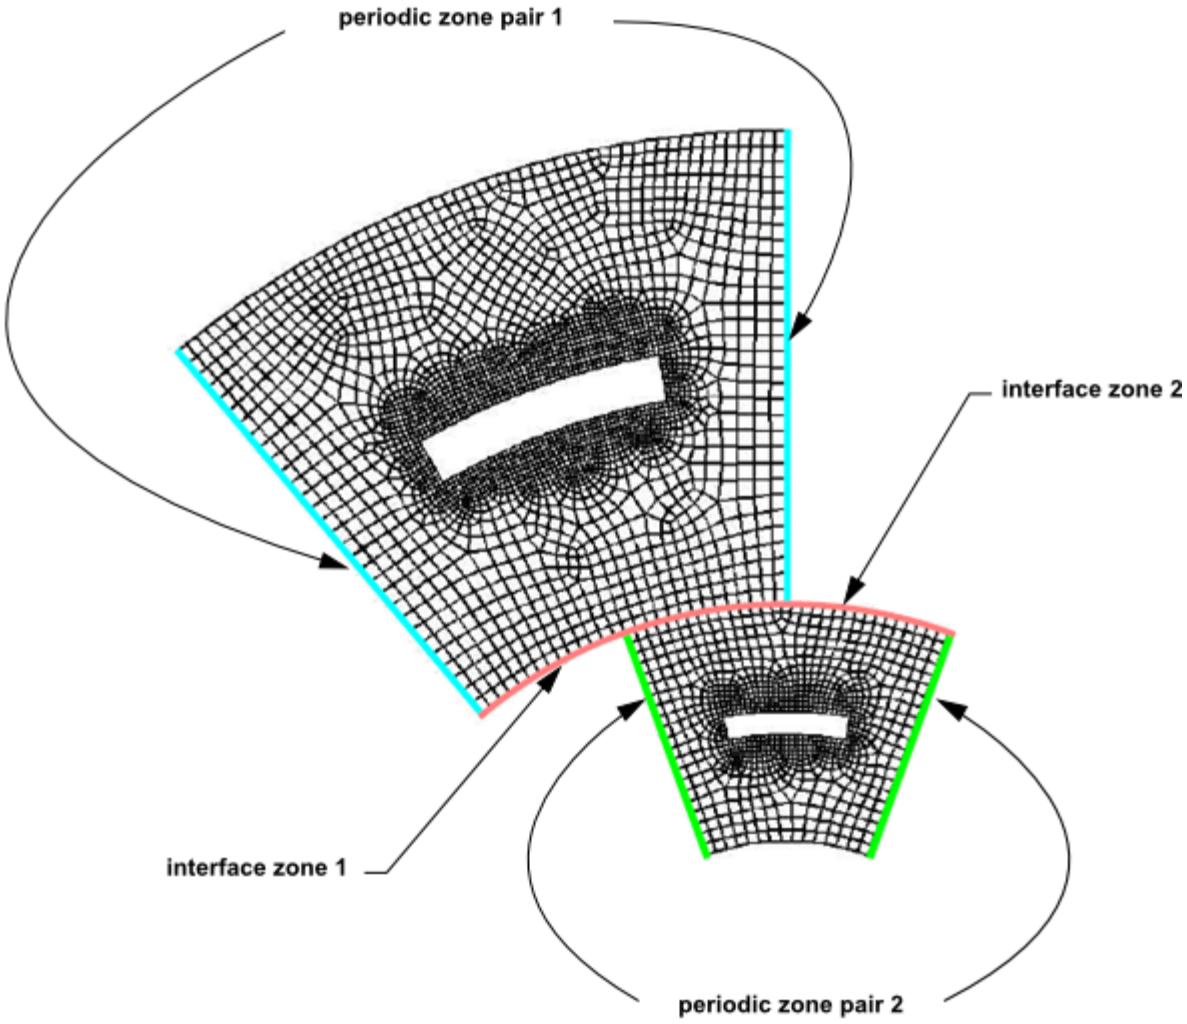
The periodic repeats option is not supported if the interface zone is adjacent to a solid zone.

Figure 6.35: Translational Non-Conformal Interface with the Periodic Repeats Option



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information
of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.36: Rotational Non-Conformal Interface with the Periodic Repeats Option



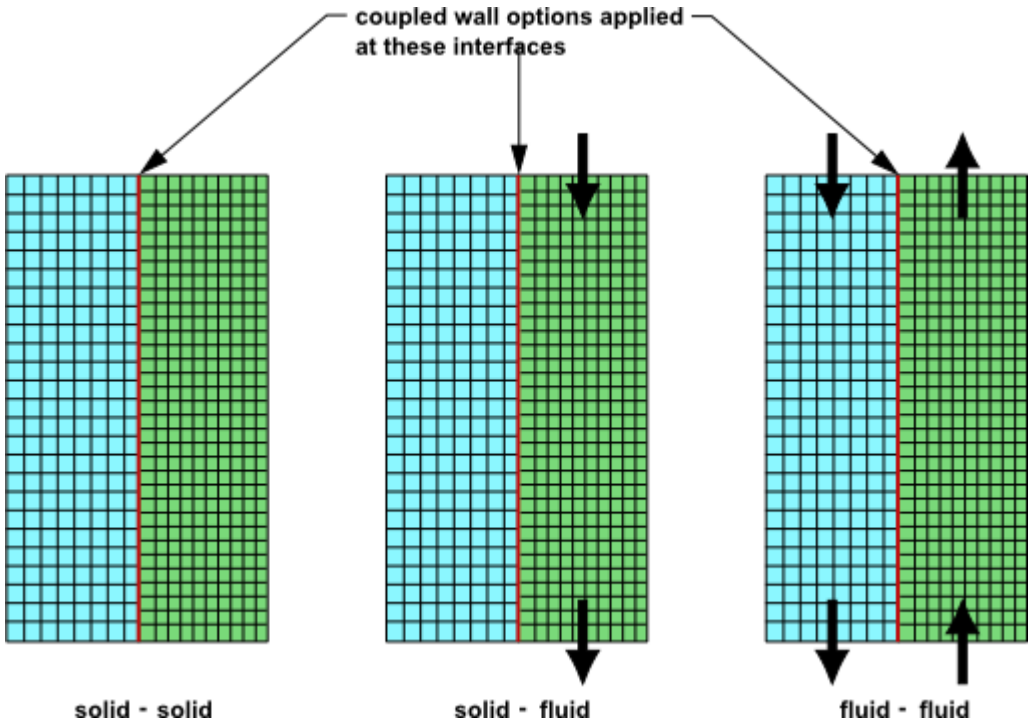
6.6.1.3. The Coupled Wall Option

As described previously, the typical function of non-conformal interfaces is to couple fluid zones, so as to permit fluid flow to pass from one mesh interface to the other. Another available option is to create a coupled wall boundary at the interface. In such a case, fluid flow would not pass across the interface, as the interface is acting as a wall zone. Coupled wall heat transfer, on the other hand, would be permitted. Such treatment is applied by default in the case of a solid-to-solid zone interface of different materials or a fluid-to-solid zone interface. For fluid-to-fluid zone interfaces, you must enable the **Coupled Wall** option to have such treatment; for example, you can model a thin wall or baffle separating the two fluid zones. Figure 6.37: Non-Conformal Coupled Wall Interfaces (p. 1156) illustrates coupled walls with both solid and fluid zones.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note that coupled walls can also make use of the periodic repeats option. That is, both options can be invoked simultaneously. For details see Using a Non-Conformal Mesh in Ansys Fluent (p. 1164).

Figure 6.37: Non-Conformal Coupled Wall Interfaces



6.6.1.4. Matching Option

When two interface zones do not match well (which could result from different mesh topologies, geometric misalignment, or the existence of large gaps), wall zones will be created on the interface. If, in such cases, you want to have only internal zones generated on the interface (that is, interior or wall / shadow pairs), it is best to use a matching interface. If the interface zones are completely overlapping (see Figure 6.30: Completely Overlapping Mesh Interface Intersection (p. 1149)) as opposed to partially overlapping (see Figure 6.31: Partially Overlapping Mesh Interface Intersection (p. 1150)) and so no wall zones are expected to be created on the mesh interface, it is recommended that you select the **Matching** option.

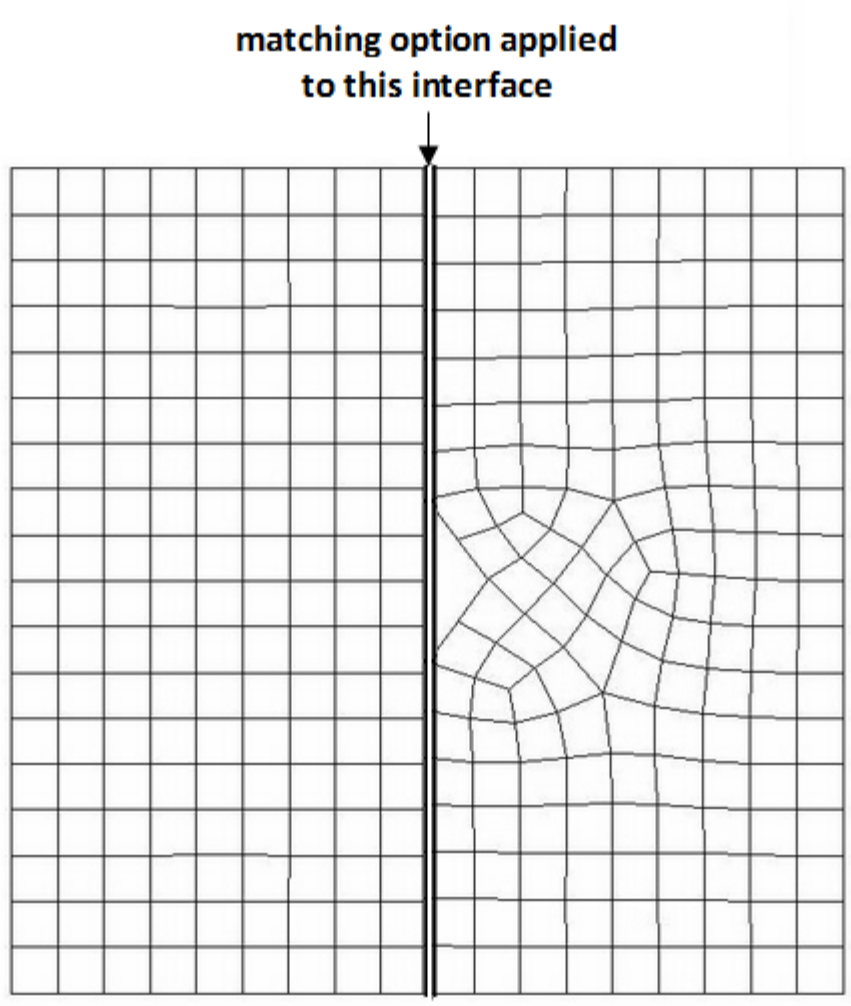
Note:

The **Matching** option is enabled by default with the **Periodic Boundary Condition** option.

Figure 6.38: Matching Non-Conformal Wall Interfaces (p. 1157) below shows two interface zones that do not match up well in the center—the interface zone on the right has an inverted spike. Even with such a large mismatch, the **Matching** option still enables you to create an interface with only the interior zone.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.38: Matching Non-Conformal Wall Interfaces



When the **Matching** option is selected, Ansys Fluent checks if one interface zone sits on top of the other and displays messages if there is a penetration of cell zones that are connected through a mesh interface (therefore making the interface invalid for use). Since the severity of zone penetration is different for matching interfaces and non-matching interfaces, Ansys Fluent displays different messages accordingly.

For example, for non-matching interfaces:

```
Info: Interface zones penetrate each other for mesh interface (interface-name). This could adversely
affect your solution.
```

Likewise, for matching interfaces:

```
Warning: Interface zones penetrate each other for mesh interface (interface-name).
         This could generate left-handed faces on the interface and make it invalid for use.
```

6.6.1.5. The Mapped Option

The **Mapped** option is an alternative approach for modeling coupled walls between zones. This approach provides better handling for interface zones that penetrate each other or have gaps

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

between them. The **Mapped** option is useful in situations where using the standard non-conformal interface formulations causes the simulation to fail (as may occur when there is interface penetration or gaps between interfaces, causing the creation of left-handed faces at the interface).

Figure 6.39: Non-Conformal Mapped Interface with a Gap and Penetration

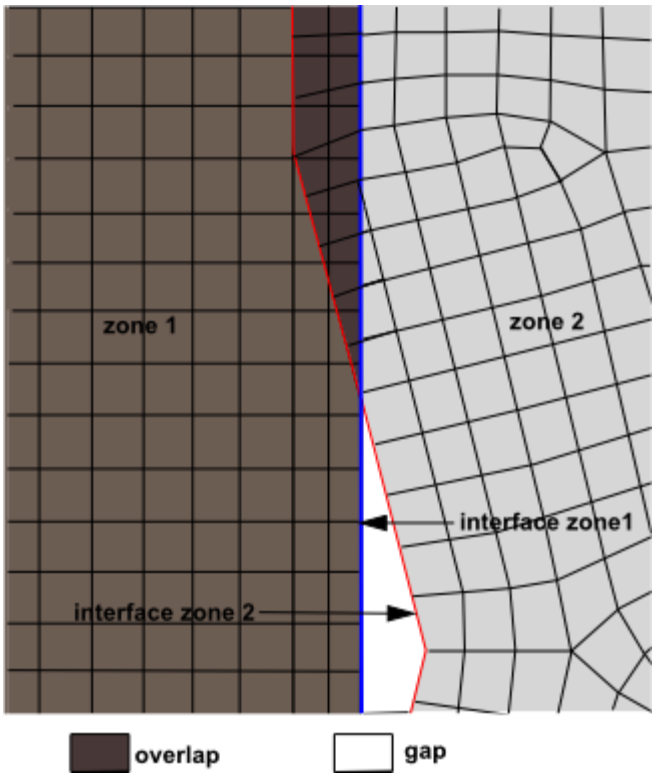


Figure 6.39: Non-Conformal Mapped Interface with a Gap and Penetration (p. 1158) shows significant penetration between the two interface zones and large gap. The mapped option allows you to create a coupled wall even with the large amount of penetration and gap shown in this image.

The **Mapped** option only works in conjunction with the **Coupled Wall** option. Enabling the **Mapped** automatically enables **Coupled Wall**.

You can use the Mapped Interface Options Dialog Box (p. 5464) to modify the global settings for the mapped interfaces, as well as to convert existing mesh interfaces (either all of them or just those that have penetrating zones) to use the **Mapped** option.

You can confirm that you created good quality mapped interfaces by performing a mesh check. If you have mapped interfaces that did not pass the quality check, Fluent will suggest that you use the text command `define/mesh-interface/improve-quality`, which allows you to increase the interface tolerance to improve the quality of the mapped interfaces.

In problems set up in version 19.2 or earlier, where you have a solid zone adjacent to a fluid zone (conjugate heat transfer) with a mapped mesh interface between them, it is recommended you switch from the explicit coupling method to the implicit method using the text command `/define/models/cht/implicit-coupling?`. The implicit method produces better convergence behavior compared to the explicit method for these fluid-solid pairs. Note that the implicit method is the now the default.

Note the following limitations when using the **Mapped** option:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The **Mapped** option can only be applied if at least one side of the interface consists of only solid zones.
- The **Mapped** option is not compatible with shell conduction.
- Thermal coupling calculations will not be performed at mapped interfaces for the Eulerian multiphase model.
- No other interface options besides **Coupled Wall** are allowed with the **Mapped** option.
- For the S2S model, the **Face to Face** basis for the view factors is not compatible with mapped interfaces for polyhedral meshes.
- Mapped interfaces are not supported with the density-based solver.
- Mapped interfaces are not supported with the Lagrangian discrete phase model.
- Mapped interfaces are not supported with moving / deforming meshes.

6.6.1.6. The Static Option

For a default mesh interface or when the **Coupled** and/or **Matching** options are enabled, Ansys Fluent will automatically create zones that will be needed if the interface should change due to motion (from moving reference frames or sliding meshes) or deformation. If you know in advance that the interface zones will not be moving or deforming relative to each other at the interface, then (and only then) it is recommended that you enable the **Static** option. The **Static** option prevents the creation of such zones, and thus reduces the memory usage and processing time (for both the creation of the interface and the running of the calculation). This reduction can be significant, especially when there are many zones on both sides of the interface.

> **Warning:**
>
> If the **Static** option is applied at an interface that does end up undergoing relative motion or deformation, the results will be incorrect.

Note that the **Static** option is not limited to steady-state cases.

6.6.1.7. Interface Zones Automatic Naming Conventions

The following sub-sections describe the automatic naming conventions for each type of non-conformal interface. Note that in these descriptions:

- <*mesh interface name*> is user specified
- <*connection number side 1*> is a value between 1 and *m*, where *m* is the number of zones in interface zone side 1
- <*connection number side 2*> is a value between 1 and *n*, where *n* is the number of zones in interface zone side 2
- <*side number*> is 1 or 2

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.6.1.7.1. Default (No Options Enabled)
6.6.1.7.2. Periodic Boundary Condition
6.6.1.7.3. Periodic Repeats
6.6.1.7.4. Coupled Wall
6.6.1.7.5. Matching
6.6.1.7.6. Mapped
6.6.1.7.7. Static

6.6.1.7.1. Default (No Options Enabled)

The automatic naming convention for the non-overlapping zones is as follows: <*interface zone name*> - *non-overlapping*.

The automatic naming convention for interface wall zone side 1 is as follows: <*mesh interface name*> - *wall1* - <*connection number side 1*> - <*connection number side 2*>.

The automatic naming convention for interface wall zone side 2 is as follows: <*mesh interface name*> - *wall1* - <*connection number side 1*> - <*connection number side 2*> - *shadow*.

The automatic naming convention for interface interior zones from a one-to-one pairing (the default) is as follows: <*mesh interface name*>.

The automatic naming convention for interface interior zones that are from a many-to-many pairing is as follows: <*mesh interface name*> - *interior* - <*connection number side 1*> - <*connection number side 2*>.

6.6.1.7.2. Periodic Boundary Condition

The automatic naming convention for the non-overlapping zones is as follows: <*interface zone name*> - *non-overlapping*.

The automatic naming convention for interface interior zones is as follows: <*mesh interface name*>.

6.6.1.7.3. Periodic Repeats

The automatic naming convention for interface interior zones is as follows: <*mesh interface name*> - *periodic*. Note that unnamed zones may be created for use in the solver and cannot be changed or modified by the user.

6.6.1.7.4. Coupled Wall

The automatic naming convention for the non-overlapping zones is as follows: <*interface zone name*> - *non-overlapping*.

The automatic naming convention for interface wall zones from a one-to-one pairing (the default) is as follows: <*mesh interface name*> and <*mesh interface name*> - *shadow*.

The automatic naming convention for side 1 of interface wall zones that are from a many-to-many pairing is as follows: <*mesh interface name*> - *wall1* - <*connection number side 1*> - <*connection number side 2*>; and then interface wall zone side 2 is named: <*mesh interface name*> - *wall1* - <*connection number side 1*> - <*connection number side 2*> - *shadow*. For example:

```

6.6.1.7.7. Static

The **Static** option does not affect the naming conventions of the zones; that is, the zone names will be based entirely on the other settings in the **Interface Options** group box of the **Edit Mesh Interfaces** or **Create/Edit Mesh Interfaces** dialog box.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.6.2. Non-Conformal Interface Algorithm

In the current version of Ansys Fluent, non-conformal interface calculations are handled using one of three approaches depending on the type of interface. **Coupled Wall** interfaces are handled using interface boundary metrics and **Mapped** interfaces use a projection approach. The interface boundary metrics and projection approach are both robust algorithms that avoid creating left-handed faces and are particularly useful when you have complex geometries.

The remaining types of non-conformal interfaces are handled using a virtual polygon approach. The virtual polygon approach stores the area vector and centroid of the polygon faces. This approach does not involve node movement and cells are not necessarily water-tight cells. Hence gradients are corrected to take into account the missing face area. Note that in transient cases, the stationary non-conformal interfaces will be automatically preserved by Ansys Fluent during mesh update.

Previous versions (16.0 and earlier) of Fluent used the virtual polygon approach for all non-conformal interfaces. The interface boundary metrics is a more robust approach for creating coupled wall interfaces than the virtual polygon approach because it avoids creating left-handed faces. Older versions of Fluent (6.1 or earlier) used a triangular face approach, which triangulated the polygon intersection faces and stored triangular faces. This approach involved node movement and water-tight cells, and was not as stable as the virtual polygon approach. Note that case files created in releases prior to 16.0 can be read and run normally in the current version of Fluent unless you recreate any of the interfaces. Recreated coupled wall interfaces will use interface boundary metrics and all other recreated interfaces will use the virtual polygon approach.

For a sliding mesh case that has interface zones that do not match well at the mesh interface, the resulting mesh may have left-handed faces. Such faces can cause the mesh to be invalid, and so Ansys Fluent automatically attempts to make the faces "right handed". If any left-handed faces remain, you can remove them using the `define/mesh-interfaces/remove-left-handed-interface-faces?` text command.

Left-handed cells can also be created for the geometries that contain sharp edges and corners, which may affect the final solution. For such geometries, you should first separate the zones and then create the interfaces separately to get the better solution.

The additional input of the angle/translation vector at the `angle/translation-vector` prompt in the console may be required to recreate face-periodic interfaces. Also, with the current mesh interface algorithm in parallel, there is no need for encapsulation.

6.6.3. Requirements and Limitations of Non-Conformal Meshes

This section describes the requirements and limitations of non-conformal meshes:

- The mesh interface can be of any shape (including a non-planar surface, in 3D), provided that the two interface boundaries are based on the same geometry. If there are sharp features (for example, 90-degree angles) or curvature in the mesh, it is especially important that both sides of the interface closely follow that feature.

  For example, consider the case of two concentric circles that define two fluid zones with a circular, non-conformal interface between them, as shown in Figure 6.40: A Circular Non-Conformal Interface (p. 1163). Because the node spacing on the interface edge of the outer fluid zone is coarse

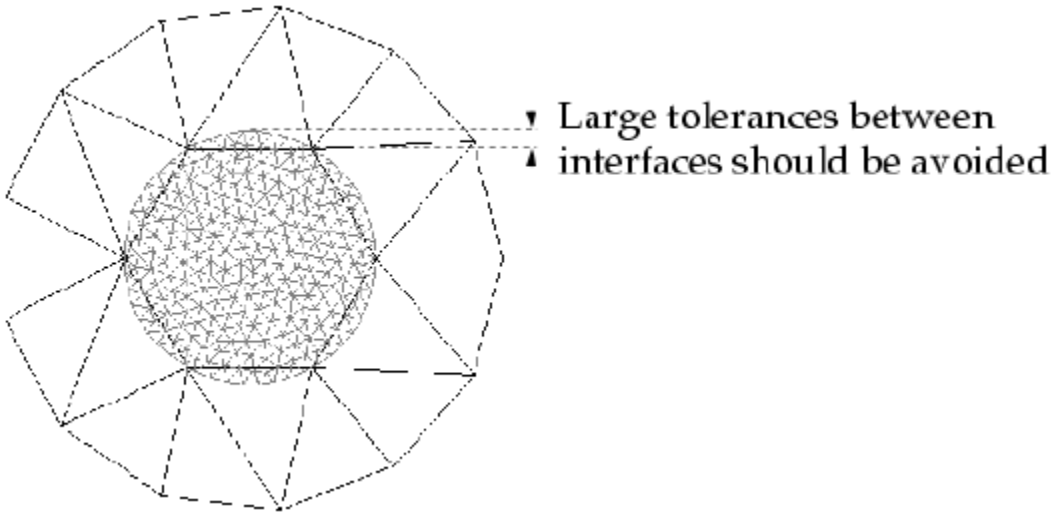
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

compared to the radius of curvature, the interface does not closely follow the feature (in this case, the circular edge.)

Important:

The maximum tolerance between two interfaces should not be larger than their adjacent cell size at that location That is no cell should be completely enclosed between two interfaces.

Figure 6.40: A Circular Non-Conformal Interface



- Non-conformal interface surfaces can be visualized, but they do not participate in postprocessing operations. That is, they will show zero values while the corresponding parent walls are non-zero.
- If you create a single mesh with multiple cell zones separated by a non-conformal boundary, you must be sure that each cell zone has a distinct face zone on the non-conformal boundary.

  The face zones for two adjacent cell zones will have the same position and shape, but one will correspond to one cell zone and one to the other. It is also possible to create a separate mesh file for each of the cell zones, and then merge them as described in Reading Multiple Mesh/Case/Data Files (p. 1135).
- All periodic zones must be correctly oriented (either rotational or translational) before you create the non-conformal interface.
- In order for the periodic boundary condition option or periodic repeats option to be valid, the edges of the second interface zone must be offset from the corresponding edges of the first interface zone by a uniform amount (either a uniform translational displacement or a uniform rotation angle). This is not true for non-conformal interfaces in general.

  The periodic boundary condition option has the additional requirement that the angle associated with a rotationally periodic must be able to divide 360 without remainder.
- The periodic repeats option requires that some portion of the two interface zones must overlap (that is, be spatially coincident).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The periodic repeats option requires that the non-overlapping portions of the interface zones must have identical shape and dimensions. If the interface is part of a sliding mesh, you must define the mesh motion such that this criterion is met at all times.
- Note that for 3D cases, you cannot have more than one pair of conformal periodic zones adjacent to each of the interface zones.
- You must not have a single non-conformal interface where part of the interface is made up of a coupled two-sided wall, while another part is not coupled (that is, the normal interface treatment). In such cases, you must break the interface up into two interfaces: one that is a coupled interface, and the other that is a standard fluid-fluid interface. See Using a Non-Conformal Mesh in Ansys Fluent (p. 1164) for information about creating coupled interfaces.
- For simulations that involve the Fluent, Mechanical, and Meshing applications, meshing problems can arise in instances where there are multiple regions and contacts between them. In Fluent, a zone can only exist in a single contact region. The Mechanical and Meshing applications both use a different approach concerning contact regions when compared to Fluent.
- Fluid zones designated as 3D fan zones cannot have non-conformal interfaces.
- When you read a non-conformal interface case file into meshing mode and later switched to the solution mode, note the following limitations:
  - Zone IDs may match, however, the corresponding zone names may be inconsistent.
  - Boundary conditions on intersected threads are not preserved.
  - Unassociated (dangling) non-conformal interface (NCI) surfaces remain present.

6.6.4. Using a Non-Conformal Mesh in Ansys Fluent

If your multiple-zone mesh includes non-conformal boundaries, check if the mesh meets all the requirements (listed in Requirements and Limitations of Non-Conformal Meshes (p. 1162)). This ensures that Ansys Fluent can obtain a solution on the mesh. Then do the following:

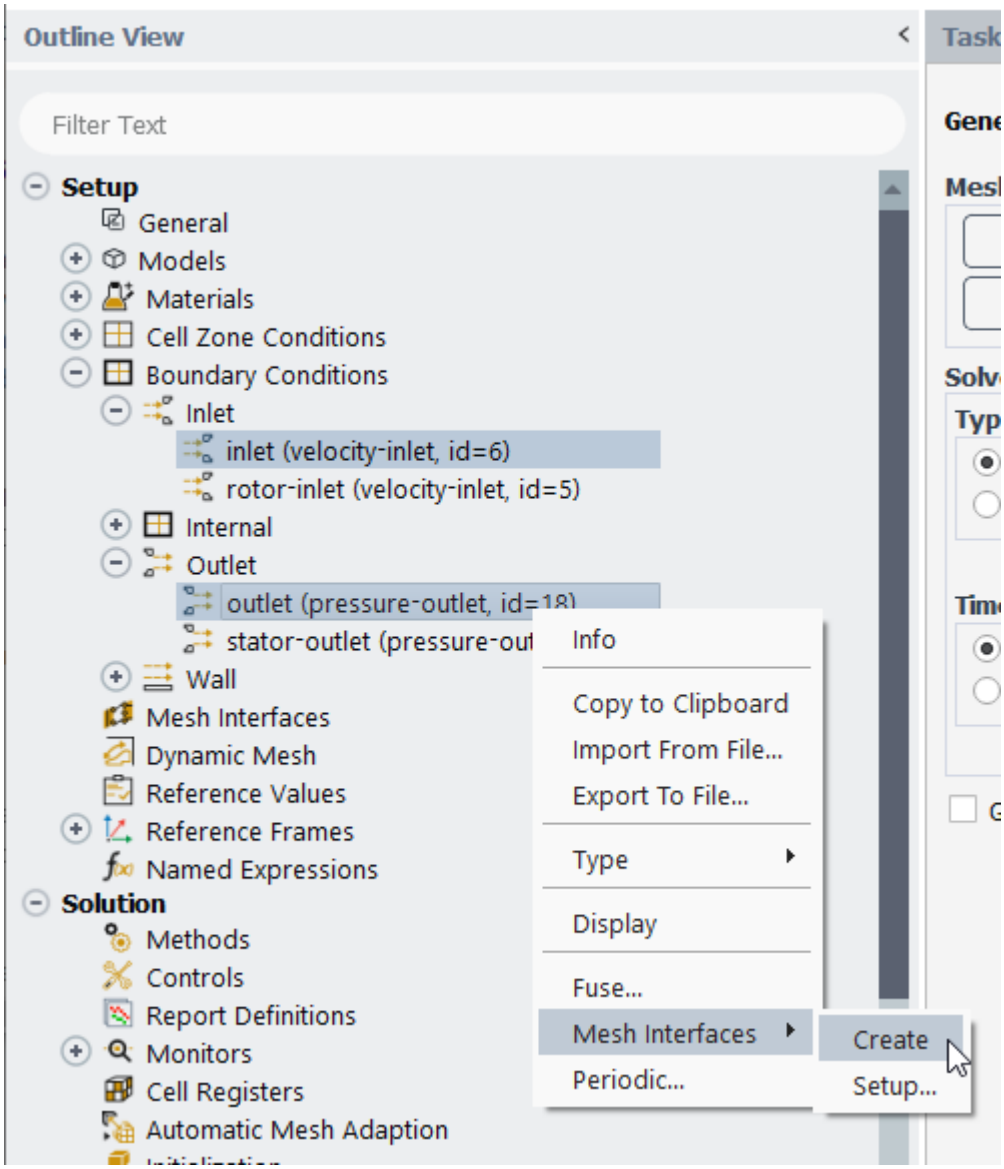
1. Read the mesh into Ansys Fluent. If you have multiple mesh files that have not yet been merged, first follow the instructions in Reading Multiple Mesh/Case/Data Files (p. 1135) to merge them into a single mesh.
2. Change the type for all of the zones that make up the non-conformal boundaries as needed. When using the default one-to-one interface creation method, change them to **interface** or **wall** if you plan to use the **Mesh Interfaces** dialog box; if you instead plan to use the right-click menu in the outline view or the text command interface, they can be any external boundary zone type. When using the many-to-many interface creation method, you must change them all to type **interface**. For details on changing the zone type, see Changing Cell and Boundary Zone Types (p. 1279).

   Setup → Boundary Conditions
3. By default, the one-to-one interface method is enabled for creating mesh interfaces, so that a single zone is assigned to each side of all of the resulting mesh interfaces. This method has the following advantages over the many-to-many method (which can produce mesh interfaces that have multiple zones on one or both sides):

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- It allows you to have single boundary zones be a part of multiple mesh interfaces, so that it is not necessary to break up large boundary zones in the meshing mode of Fluent prior to creating mesh interfaces (which may compromise the quality of the interface, and is not available for polyhedral meshes). This can improve the accuracy / robustness of the simulation.
- It allows additional boundary zone types besides interface zones to form the two sides a mesh interface:
  - When using the **Mesh Interfaces** dialog box (as described in a later step), you can select wall zones. This can simplify your setup when your case has a large number of wall zones, if only some of them will be part of a non-conformal interface.
  - When using the text command interface or selecting them in the outline view and using the right-click menu (**Mesh Interfaces** / **Create**), you can select any type of external boundary zone (that is, any zone that is connected with the cells on only side).

Figure 6.41: Pairing Boundary Zones Using the Right-Click Menu



- It allows you to create a mesh interface between two zones that are not overlapping at all. This can be useful when setting up a sliding mesh simulation in which the zones begin without overlap, and then slide into a position that includes overlap. Note that to do this, you must select only two zones during the creation step.

You must weigh the advantages listed above against the following limitations:

- No interface options can be enabled at the time of creation, except for the coupled wall option that is automatically enabled for solid-to-fluid/solid mesh interfaces.
- The only editing you can do to such a mesh interface after it has been created is to change the name and/or apply a coupled wall boundary condition (as described in a later step).

You may want to disable the one-to-one interface creation method in order to use certain options, such as the **Periodic Boundary Condition** option or the **Mapped** option. You can disable the one-to-one method by using the following text command:

`define → mesh-interfaces → one-to-one-pairing?`

Note that all of the mesh interfaces in a case file should be created using the same method. If mesh interfaces already exist and you use the previous text command to change the method, you will be prompted to authorize that the existing mesh interfaces are deleted (when switching to the many-to-many method) or converted (when switching to the one-to-one method). When converting, all incompatible settings will be disabled. Conversion can be useful if you want to update old case files that were created in an earlier version of Fluent when the one-to-one method was not available or was not enabled by default.

4. (optional) When using the default one-to-one interface creation method, there are optional settings that may be useful:

   - You can define settings related to the names of the resulting mesh interfaces.

     One option pertains to the suffix added to the end of the name: by default the suffix includes the names of the associated boundary zones, and you can use the following text command to instead specify that the suffix is omitted, replaced with the IDs of the boundary zones, or replaced with the names of the adjacent cell zones.

     `define → mesh-interfaces → auto-options → naming-option`

     You can also change the default interface name prefix by using the following text command:

     `define → mesh-interfaces → auto-options → set-default-name-prefix`

   - You can enable the following text command so that the boundary conditions of the original zones are copied to the resulting coupled wall pair when a mesh interface is created at a solid-to-solid zone interface of different materials or a fluid-to-solid zone interface. This can save you from having to edit such zones later on. Note that the coupled wall pair is thermally coupled.

     `define → mesh-interfaces → coupled-interfaces-inherit-bcs?`

   - If you want to ensure that mesh interfaces are only created between different cell zones, you can enable the following text command:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

`define` → `mesh-interfaces` → `auto-options` → `pairing-between-different-cell-zones-only?`

- When more than two zones are selected in the **Boundary Zones** group box in the **Mesh Interface** dialog box, a default tolerance is used to determine which zones can be paired up to make the mesh interfaces. This default tolerance may not be suitable for your application if there are gaps, thin layers, and/or complex geometries. For such cases, you can enable the use of adjustable tolerances that attempt to automatically adapt to your geometry and produce the desired mesh interfaces by using the following text command:

  `define` → `mesh-interfaces` → `auto-options` → `set-one-to-one-pairing-tolerance`

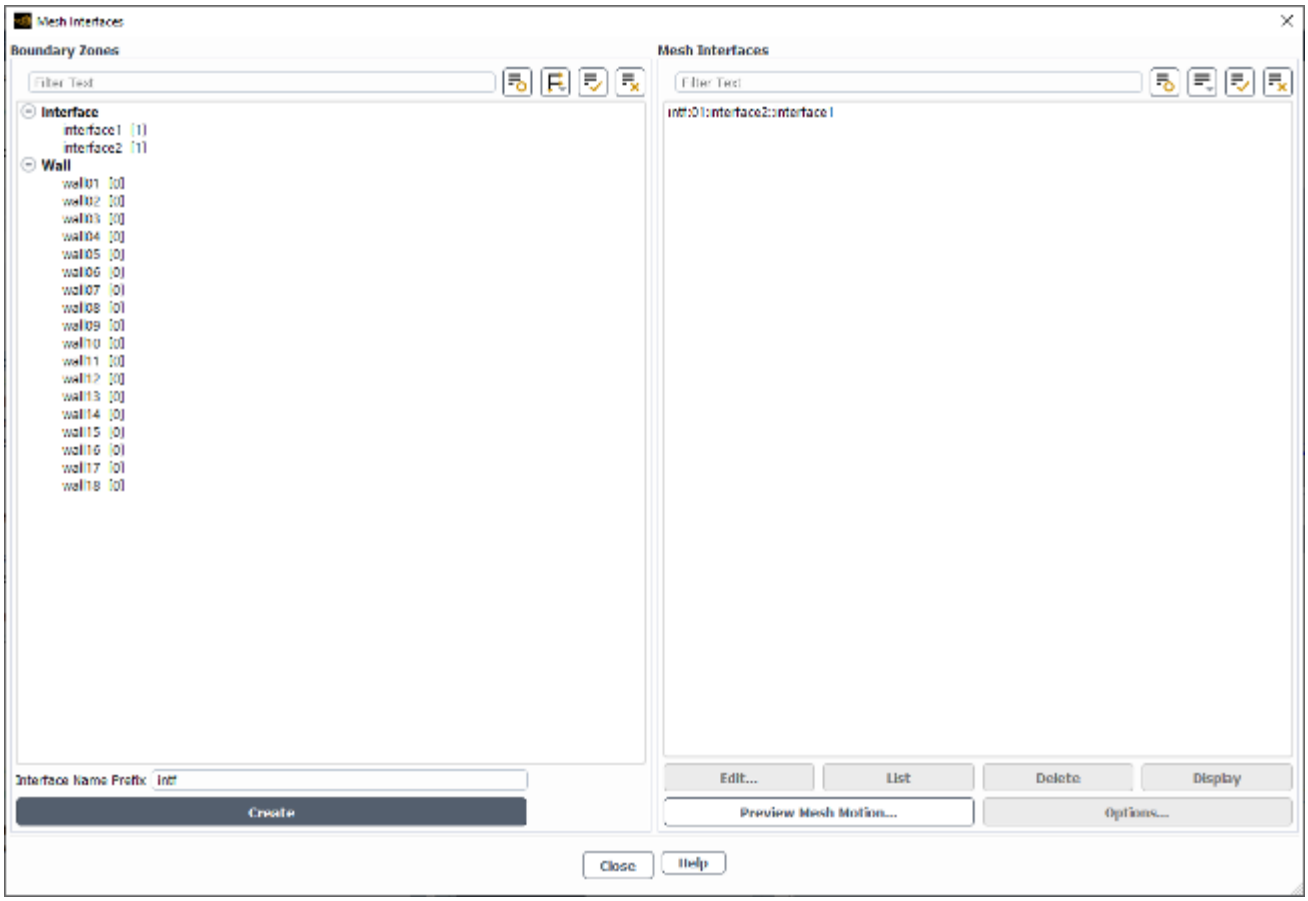
- You can use the following text command to set the minimum area percentage of overlap for mesh interface creation. If zones are paired using the automatic method (as described in a later step), after the mesh interfaces are created, a check will be done: if the area that the two zones overlap divided by the area of the zone is less than this value for both zones in any mesh interface, then that mesh interface will be deleted. This can help you avoid unnecessary or unintentional mesh interfaces. By default the minimum area percentage is set to 0, so no pairings are deleted. When you are setting up a sliding mesh simulation in which the zones begin with little or no overlap and then slide into a position that includes more overlap, you should make sure the minimum area percentage is set such that it does not delete your intended mesh interface.

  `define` → `mesh-interfaces` → `auto-options` → `set-minimum-area-percentage`

5. Open the Mesh Interfaces Dialog Box (p. 5468).

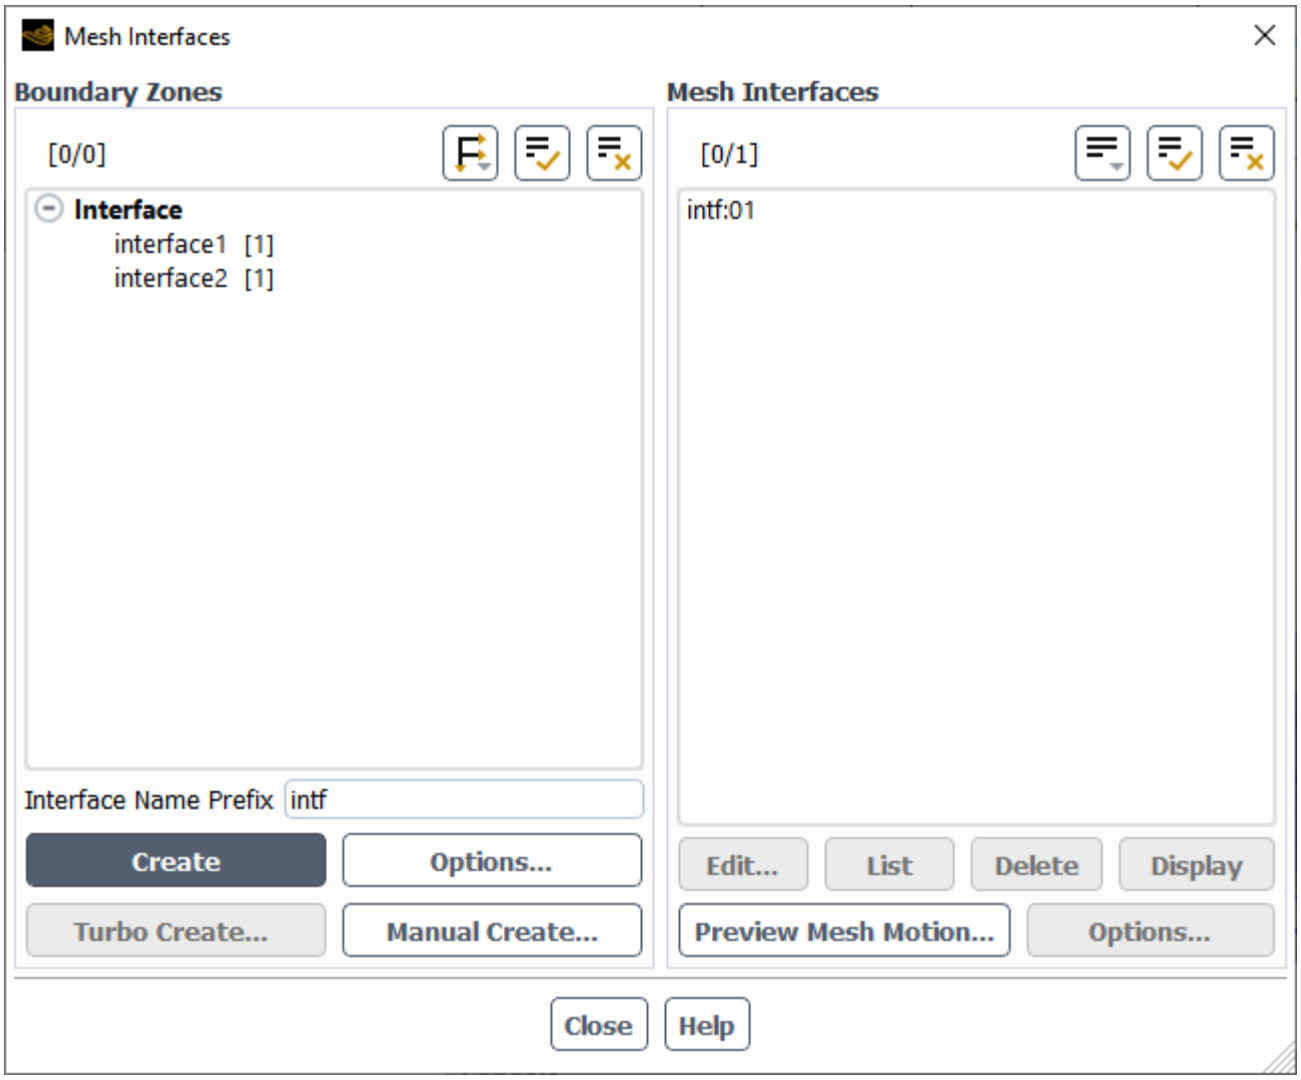
   Setup → **Mesh Interfaces** → **New...**

Figure 6.42: The Mesh Interfaces Dialog Box for the One-to-One Method



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.43: The Mesh Interfaces Dialog Box for the Many-to-Many Method



6. Create all of the mesh interfaces that use the periodic or periodic repeats option. To do so, you must disable the one-to-one interface creation method and use the manual method by clicking the **Manual Create...** button to open the Create/Edit Mesh Interfaces Dialog Box (p. 5363). For details, see Manually Creating Mesh Interfaces (p. 1179).

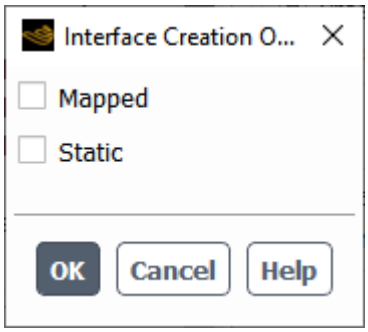
7. Create all of the mesh interfaces that *do not* use the periodic or periodic repeats option, using the automatic method. As part of this method, Fluent will automatically determine which of the selected interface boundary zones can be grouped together to form the two sides of one or more mesh interfaces.

   To use the automatic method, perform the following steps in the **Mesh Interfaces** dialog box:

   a. (optional) If you have disabled the one-to-one interface creation method, you can click the **Options...** button in the **Boundary Zones** group box to open the Interface Creation Options Dialog Box (p. 5442), and enable the settings that you want applied to all of the resulting interfaces.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.44: The Interface Creation Options Dialog Box



- You can specify that the mapped option is applied to all of the resulting interfaces for which at least one side of the interface consists of only solid zones, by enabling the **Mapped** option. Note that the mapped option will be applied regardless of the mesh quality, and the tolerance used for mapping will be that specified in the Mapped Interface Options Dialog Box (p. 5464). For more information about the mapped option, see The Mapped Option (p. 1157).

- You can specify that all of the resulting interfaces use the **Static** option, if and only if you know that the interface zones will not be moving or deforming relative to each other at the interface. While you will have the ability to enable the static option after the interfaces are created, doing so prior to creation avoids the creation of unnecessary zones (and thus saves memory usage and processing time, which can be significant when you have selected many **Boundary Zones** in the **Mesh Interfaces** dialog box).

b. Select the zones in the selection list in the **Boundary Zones** group box that you want paired. You may want to select only some of the zones, such as when you want the resulting mesh interfaces to have different settings in the **Interface Creation Options** dialog box (as described in the previous step), or different name prefixes (as described in the steps that follow); for example, you could select only the interface zones from the front half of a model, and then have all of the resulting mesh interfaces named with the prefix "front". If you are setting up a sliding mesh simulation in which the zones begin with no overlap, and will later slide into a position that includes overlap, you must select only two zones at a time.

   Note that each zone in this list has a number in brackets on the right side (for example, **[0]**). This number indicates how many mesh interfaces it is already a part of, as a result of any previous acts of mesh interface creation. Note that a boundary zone can only be used in multiple mesh interfaces when those mesh interfaces are created when the default one-to-one interface creation option is enabled.

c. Enter the **Interface Name Prefix** you want applied to all of the resulting interfaces.

d. Click the **Create** button in the **Mesh Interfaces** dialog box to create the interfaces. The resulting interfaces will be added to the **Mesh Interfaces** list; note that if you select an item in the list, the associated zones will be highlighted in the **Boundary Zones** group box (and vice versa). Details about the creation process will be printed in the console, including (for one-to-one pairings) a list of the resulting mesh interfaces with the area percentage that each boundary zone overlaps the other.

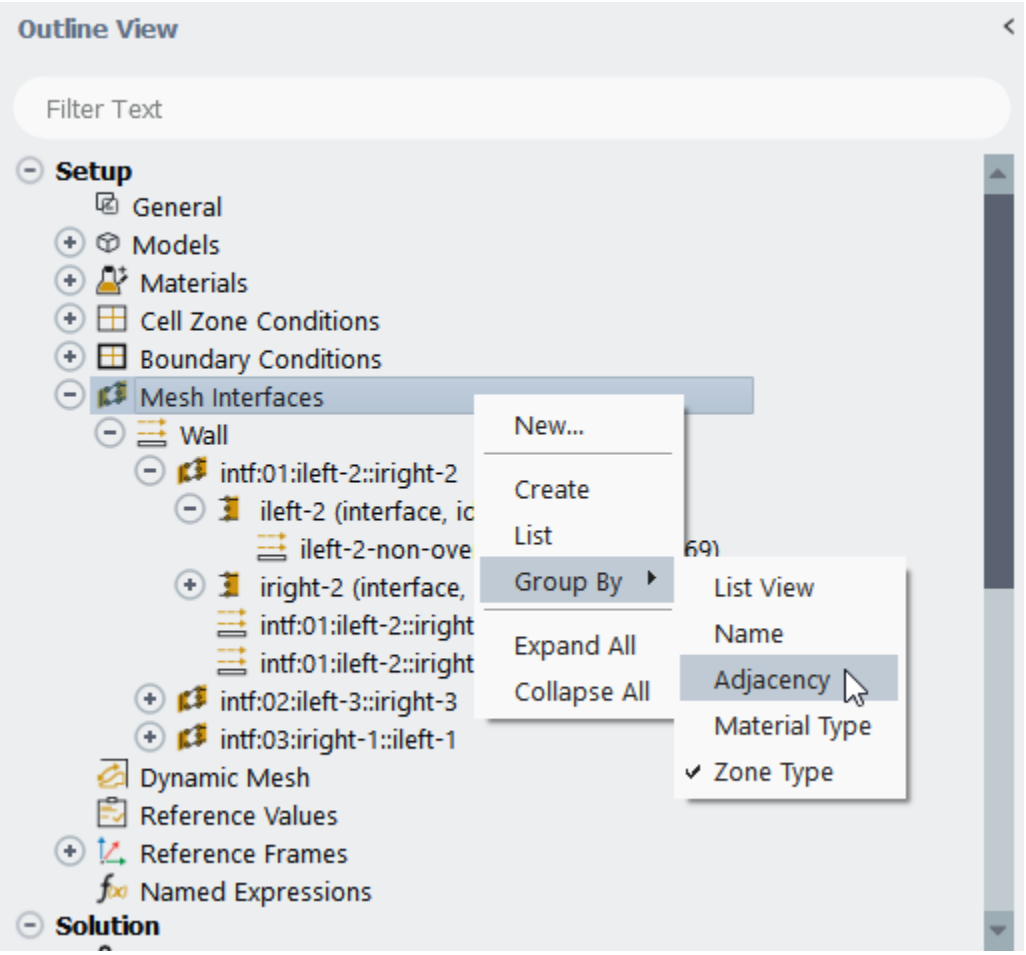
8. After creating mesh interfaces, you can manage them from the outline view tree (under **Setup** / **Mesh Interfaces**) or from the **Mesh Interfaces** dialog box. Note that for cases with only one-to-one mesh interfaces:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The individual mesh interfaces listed in the outline view tree have nodes that can be expanded to list all of the associated boundary zones (which have icons to indicate their type). By default, this also includes the associated non-overlapping zones and interior zones, and this is the only place they are listed in the outline view; you can choose to instead have them listed under **Setup** / **Boundary Conditions** under their zone types, by enabling the **Show interface children** option in **Appearance** branch of the **Preferences** dialog box (accessed through **File**/**Preferences...**).

  Using the right-click menu, you can choose to display the mesh in a list view or grouped by the names, the adjacent cell zones, the materials on either side (for example, **fluid-fluid**), and the zone types (that is, whether it includes an internal boundary or a wall because the adjacent cell zones are similar or dissimilar material types, respectively).

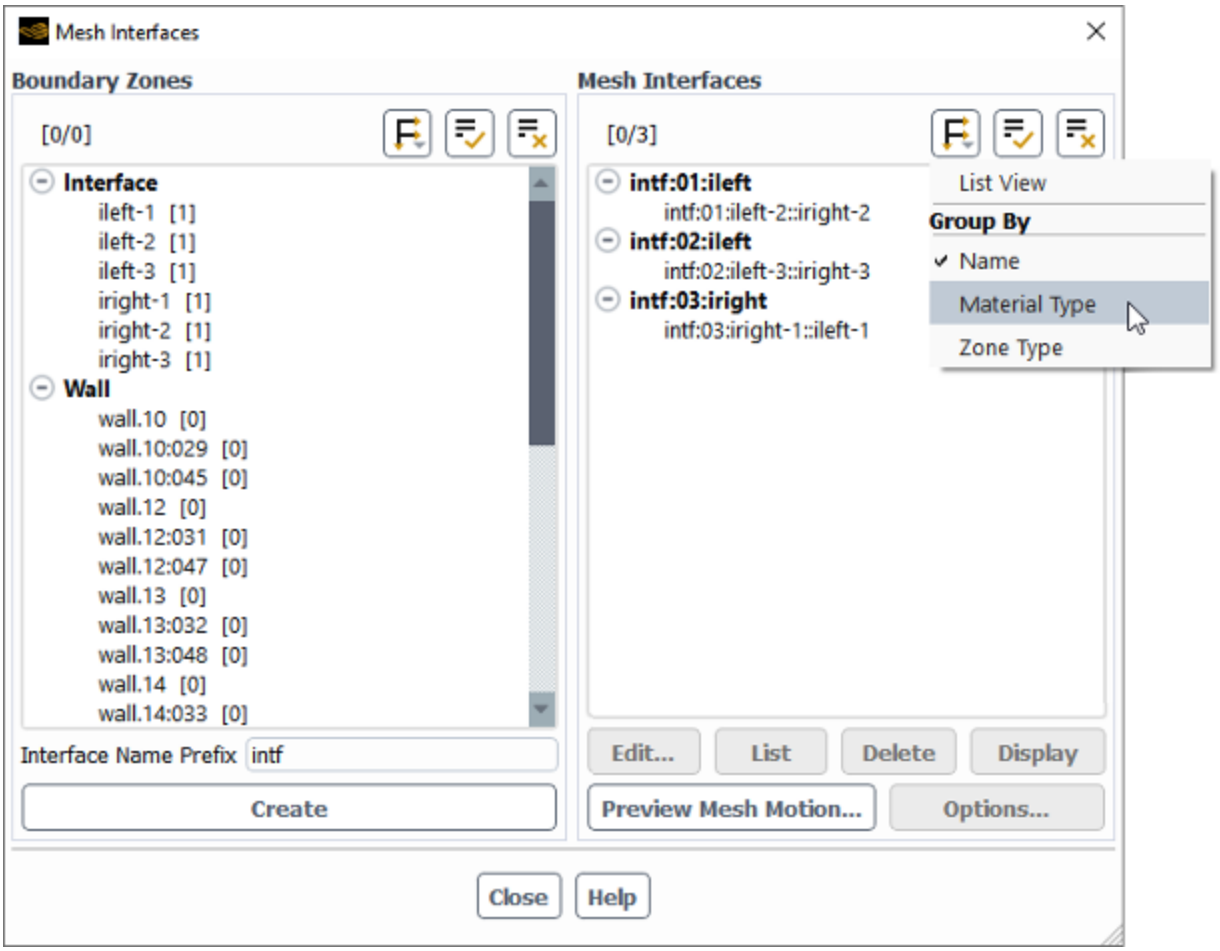
Figure 6.45: Managing One-to-One Interfaces from the Outline View Tree



- All of the outline view tree grouping options (except for the adjacent cell zones option) are also available in the **Mesh Interfaces** group box of the **Mesh Interfaces** dialog box, through the **Toggle Tree View** button.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.46: Managing One-to-One Interfaces from the Mesh Interfaces Dialog Box



9. For mesh interfaces that were created using the default one-to-one interface creation method, you can edit them in the following ways:

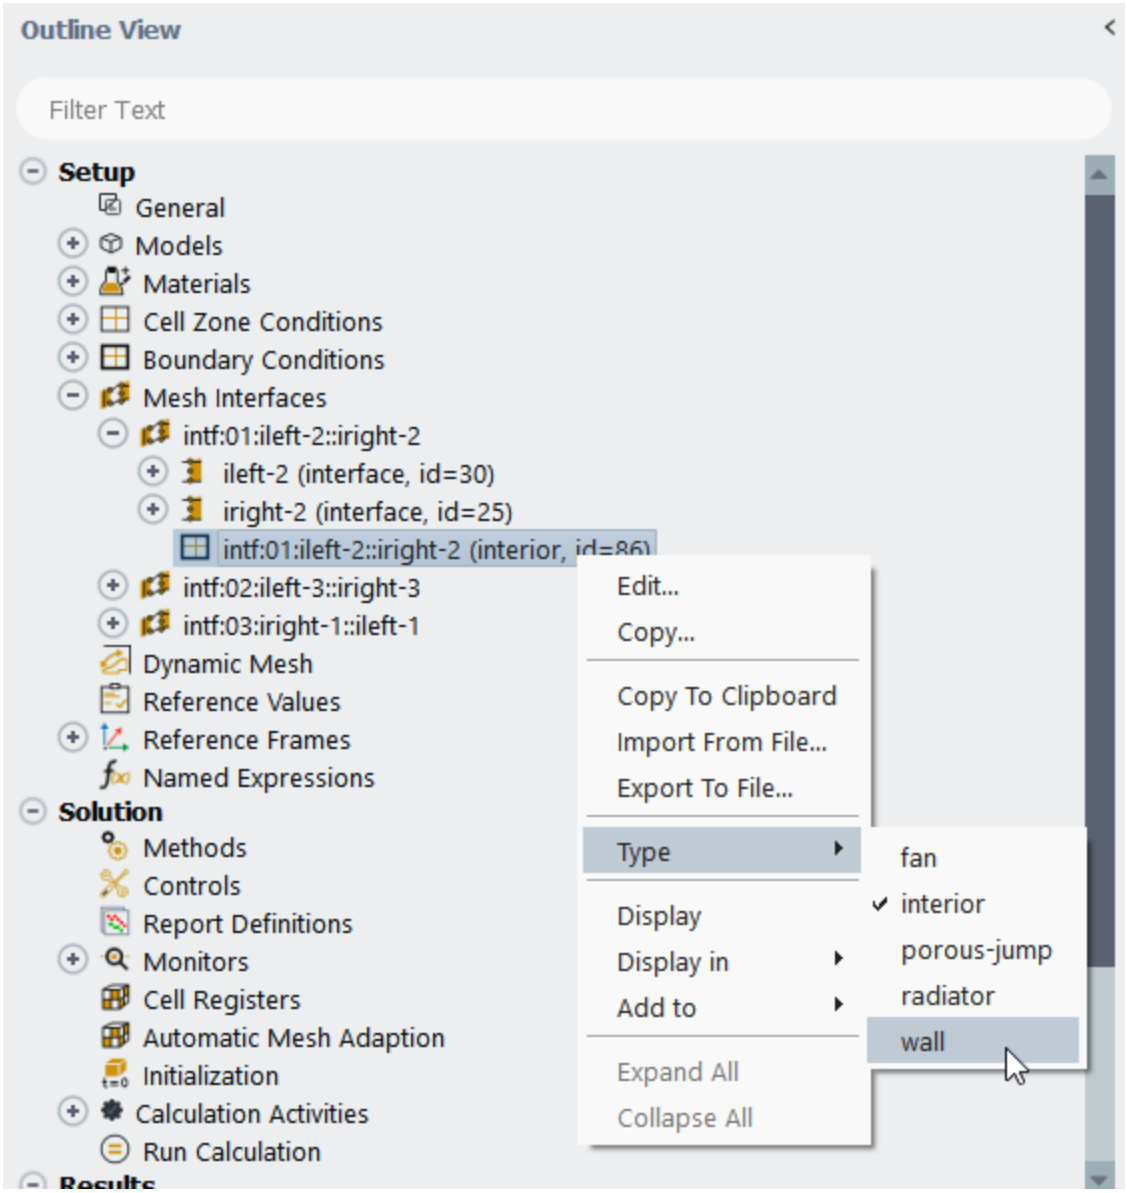
   - To edit the name, make a selection from the **Mesh Interfaces** list, click **Edit...**, and then revise the **Interface Name** in the **Edit Mesh Interface** dialog box that opens.

     Figure 6.47: The Edit Mesh Interface Dialog Box

     
   - To model a thermally coupled wall at a mesh interface between two fluid zones, right-click the associated interface interior zone in the outline view; by default it is under the associated mesh interface under **Setup** / **Mesh Interfaces**, and has the same name as the mesh interface. Then hover over **Type** and select **wall** from the menu that opens.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.48: Creating a Coupled Wall at a One-to-One Mesh Interface



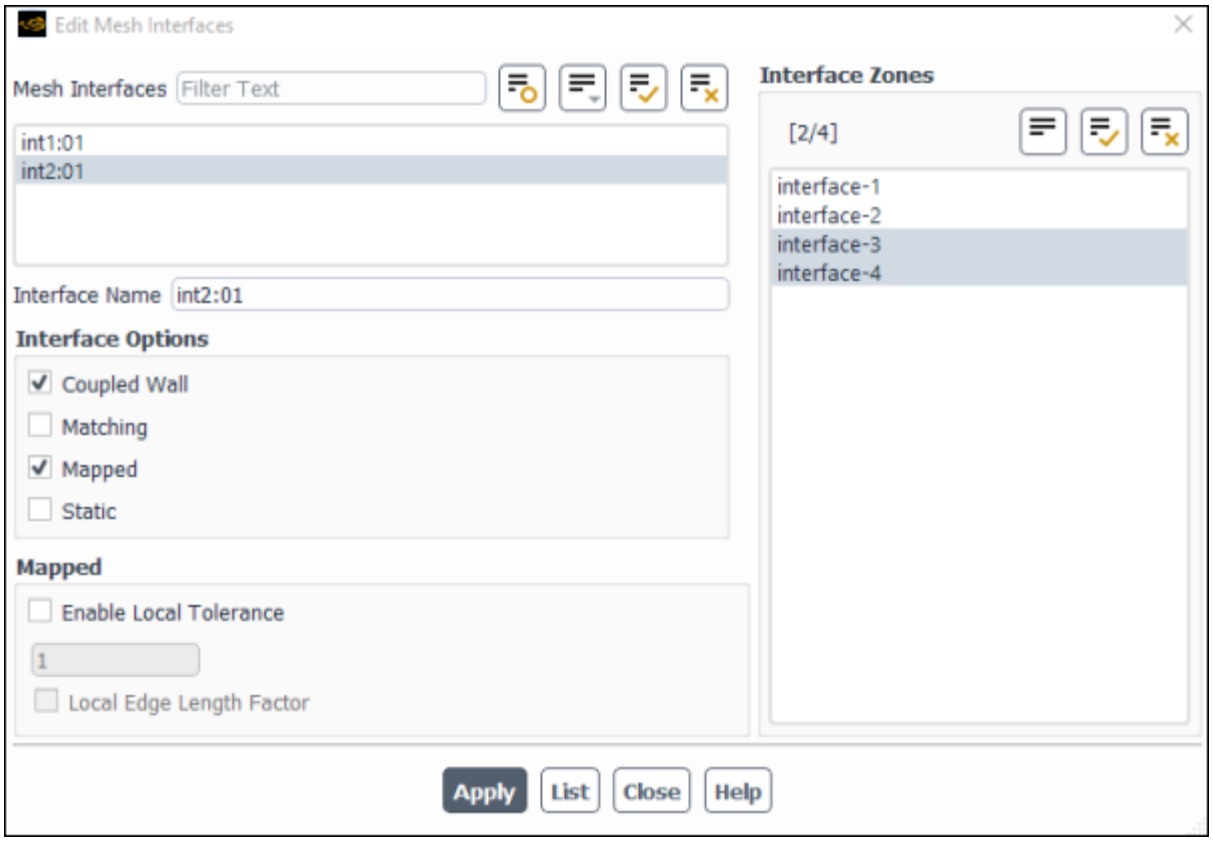
Note:

In the case of a solid-to-solid zone interface of different materials or a fluid-to-solid zone interface, by default it is treated as a coupled wall. Therefore, no action is required in the outline view tree to set up such an interface.

10. For mesh interfaces that were created with the one-to-one interface creation method disabled, you can revise them by making a selection from the **Mesh Interfaces** list, clicking **Edit...**, and then completing the setup in the Edit Mesh Interfaces Dialog Box (p. 5398) that opens.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.49: The Edit Mesh Interfaces Dialog Box



In the **Edit Mesh Interfaces** dialog box, select the **Mesh Interfaces** you want to change, revise the settings, and click **Apply**. You can edit the **Interface Name** and/or the **Interface Zones** that make up the interface (provided that the zones you select are unassigned and located appropriately), though such changes are only allowed if you select a single interface. You can select one or more interfaces and enable the following **Interface Options**; note that you can click the button to group the interfaces in the list by their currently enabled interface option(s), which allows you to select / deselect all those of a particular type by simply clicking the top-level branch.

- Enable **Coupled Wall** if you would like to model a thermally coupled wall between two fluid zones that share a non-conformal interface.

  Note:

  In the case of a solid-to-solid zone interface of different materials or a fluid-to-solid zone interface, by default it is treated as a coupled wall. Therefore, no action is required in the **Edit Mesh Interfaces** dialog box to set up such an interface.

- Enable the **Matching** option if only internal zones should be created (that is, interior or wall / shadow pairs), since the interface zones on both sides are aligned. With the **Matching** option, even interface zones that are not perfectly aligned are treated as if they are; however, if the discrepancy between the interface zones on both sides exceeds default thresholds, then warning messages will be displayed. See Matching Option (p. 1156) for more information about the recommended uses of this option.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Enable the **Mapped** option when there is penetration or large gaps between interface zones. Note that at least one side of the interface must consist of only solid zones. For additional information, see The Mapped Option (p. 1157).

  Enable **Enable Local Tolerance** in the **Mapped** group box for the selected interface, if you want to override the global tolerance defined for **Mapped Tolerance** in the Mapped Interface Options Dialog Box (p. 5464).

- Enable **Static** if and only if you know that the interface zones will not be moving or deforming relative to each other at the interface. This option will reduce memory usage and processing time during the running of the calculation, especially when there are many zones on both sides of the interface. The only options it is compatible with are the **Coupled Wall** and/or **Matching** options. See The Static Option (p. 1159) for details.

When all your changes are applied, close the **Edit Mesh Interfaces** dialog box.

Note the following:

- The **Periodic Boundary Condition** and **Periodic Repeats** options are not available in the **Edit Mesh Interfaces** dialog box, and so cannot be changed from enabled to disabled (or vice-versa) for an existing interface; to change them, you must delete the interface and create it again with those options revised.

- For interfaces that have the **Periodic Boundary Condition** option enabled, you can edit the **Type** and **Offset** from the **Edit Mesh Interfaces** dialog box. Note that the **Auto Compute Offset** option must be disabled to edit the **Offset**.

11. The buttons at the bottom of the **Mesh Interfaces** group box allow you to take further actions, such as deleting or displaying a selected interface. Note that the **Options...** button opens the Mapped Interface Options Dialog Box (p. 5464), which allows you to update which mesh interfaces use the mapped option and the related settings.

12. Additional wall and interior zones will be created (and deleted) along with the mesh interfaces. These zones will be named as described in Interface Zones Automatic Naming Conventions (p. 1159), and are visible in the outline view tree. There are times when you may need to take action on these additional zones, including the following:

    - If the two interface zones did not overlap entirely, check the boundary zones created for the non-overlapping portions to ensure that they are the proper boundary type and/or defined appropriately. The non-overlapping zones are listed in the outline view tree (as children of the associated interface boundary zones), as well as in the relevant **Interface** dialog boxes. If the zone type is not correct, you can use the Boundary Conditions Task Page (p. 4937) to change it; if the zone is not defined appropriately, double-click it in the outline view tree or click the **Edit...** button in the **Interface** dialog box, and make the necessary changes in the dialog box that opens.

    Note:

    If you delete a mesh interface that was created using the default one-to-one interface method, the type and settings of the non-overlapping zones (including any changes that you made) will be applied to the associated parent boundary zones after the deletion.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

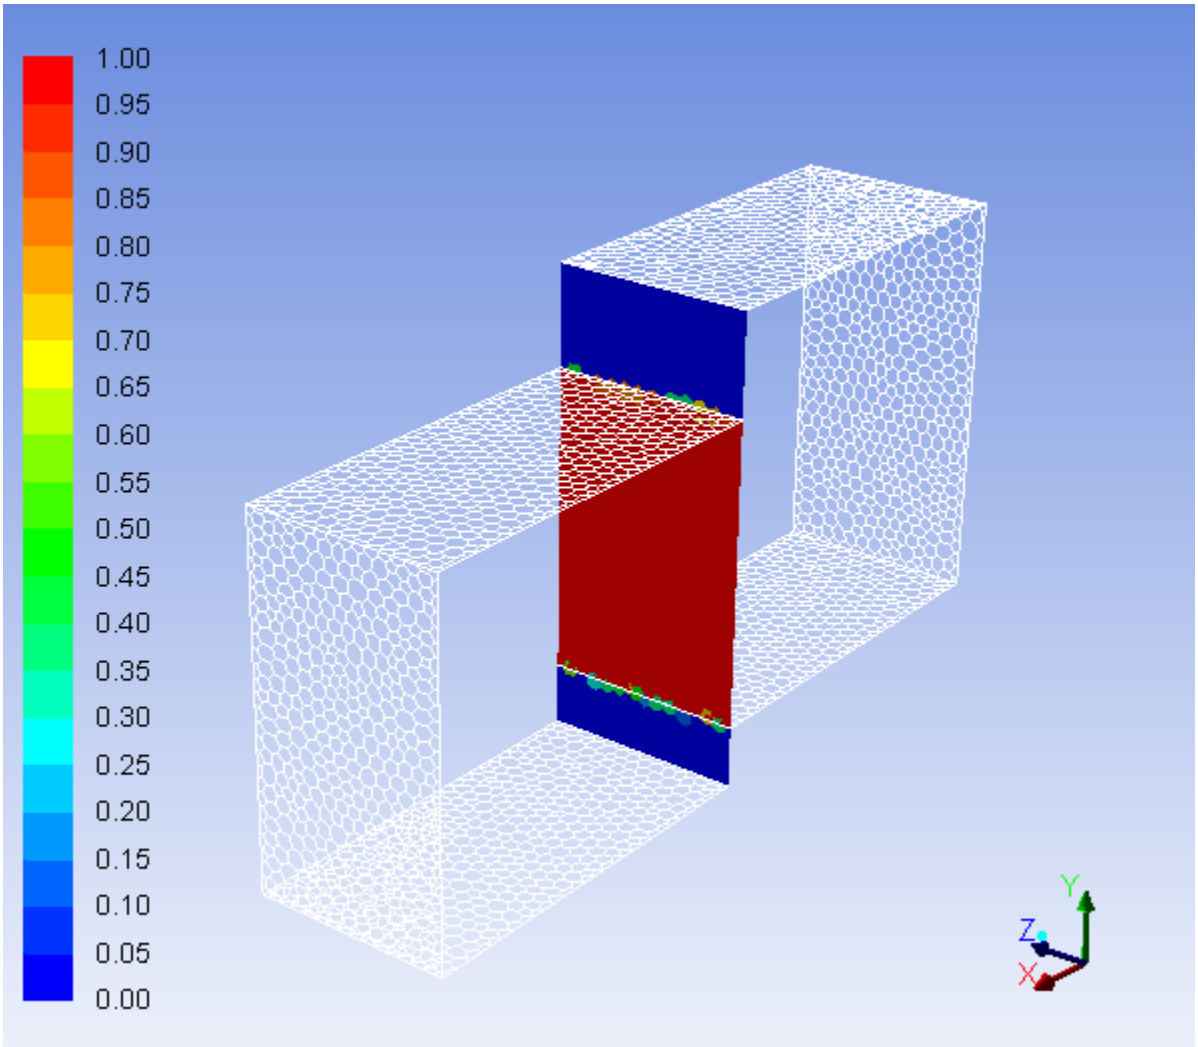
- If you have any coupled wall interfaces, define boundary conditions (if relevant) by updating the interface wall zones using the **Boundary Conditions** task page.

  Setup → **Boundary Conditions**

13. It is always a good practice to initialize the solution and review your interfaces:

- You can visualize the mesh interface(s) you have created by displaying contours of **Mesh** and **Interface Overlap Fraction** in the Contours Dialog Box (p. 5357). See Figure 6.50: Contours of Interface Overlap Fraction (p. 1176) for an example.

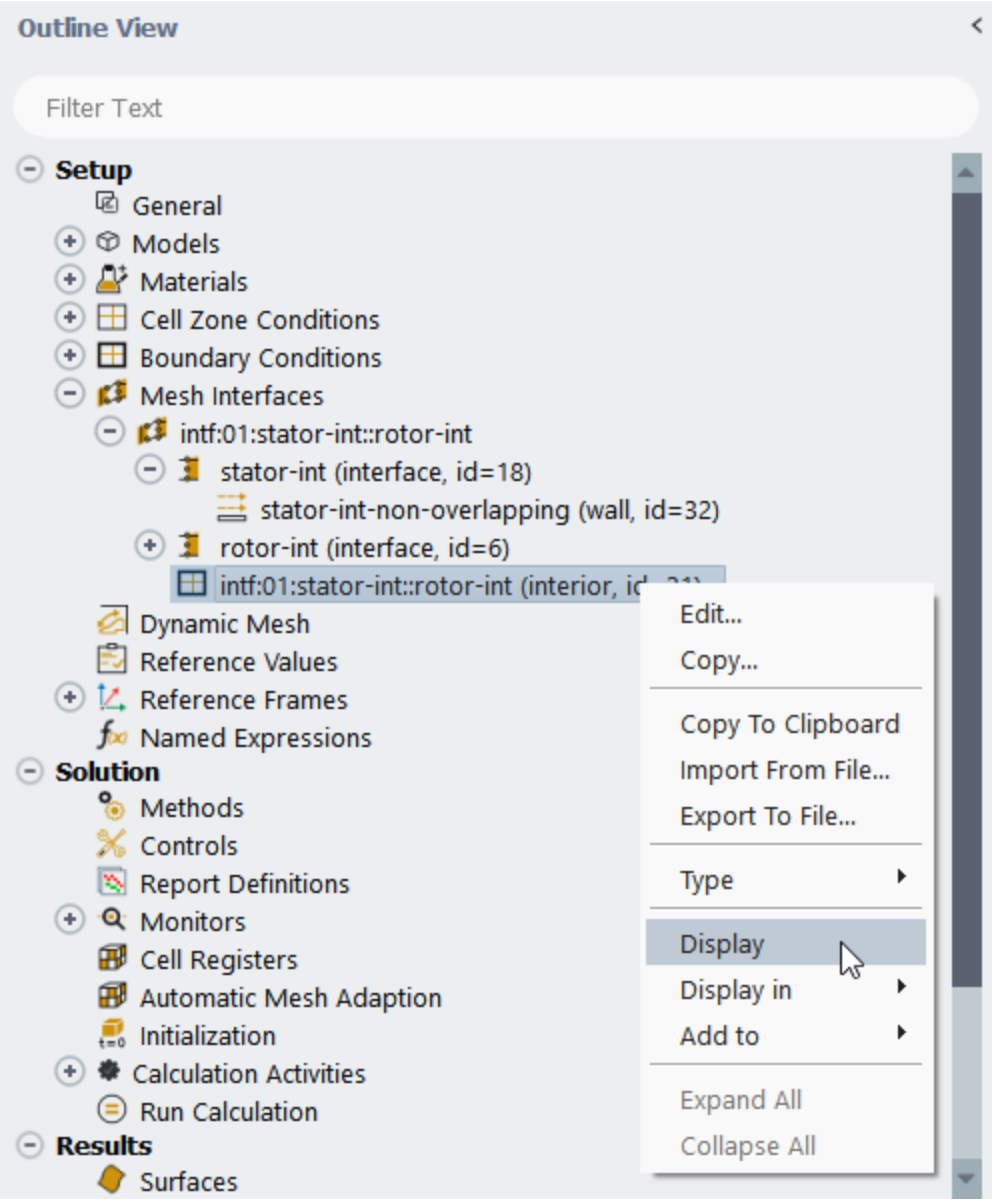
Figure 6.50: Contours of Interface Overlap Fraction



For a one-to-one mesh interface, you also have the option of displaying the intersected zone in the graphics window by using the right-click menu in the outline view tree (under the mesh interface node under **Setup** / **Mesh Interfaces**, by default). The intersected zone is of type interior or is a coupled wall (wall or wall shadow) that is generated during the mesh interface creation, and it represents the overlapping area between the two interface zones. In the same way you can also display the non-overlapping zones; note that for non-overlapping zones, the display is approximate at the boundaries of intersected zones, as whole faces will be shown or not shown depending on the location of their centroid.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.51: Displaying the Intersected Zone



- You can print information in the console about the areas of the zones associated with interfaces either by using the **List** button in the **Mesh Interfaces** dialog box or by entering the text command `define/mesh-interface/list`. The following is the information for a one-to-one mesh interface:

```
>define/mesh-interfaces/list

List of Mesh Interface Boundary Zones

  Interface Boundary:  s-1
  Area:   1.01046027e-03

                     Name                       ID         Area         Area Percentage
  ----------------------------------------  ----  -----------------  ---------------
                           intf:01:s-1::r-1    14     8.99861833e-04         89.0546%
                      s-1-non-overlapping    29     1.10513145e-04         10.9369%
```

```
  Interface Boundary:  r-1
  Area:   1.01029151e-03

                     Name                       ID         Area         Area Percentage
   ----------------------------------------  ----  -----------------  ---------------
                           intf:01:s-1::r-1    14     8.99861833e-04         89.0695%
                       r-1-non-overlapping     30     1.10303113e-04         10.9179%

List of Mesh Interface Area Percentage

                    Name                       ID          Area                Area Percentage
   ------------------------------------  --------  -----------------  ------------------------
                          intf:01:s-1::r-1        14    8.99861833e-04          89.05% / 89.07%
```

The `Area Percentage` is the `Area` of a mesh interface / non-overlapping zone divided by the area of an interface boundary. The final line lists the `Area Percentage` for both of the interface boundaries, that is, `s-1` and `r-1`, respectively.

The following is the information for a many-to-many mesh interface:

```
>define/mesh-interfaces/list

List of Mesh Interfaces

  Interface Name:     intf:01
  Interface Options:  none

       Description                    Name               ID         Area         Area Percentage
---------------------------  -----------------------  -------  -------------  ----------------
      Interface-Zone-Side-1                      s-1       18  1.01046027e-03
      Interface-Zone-Side-2                      r-1        6  1.01029151e-03
Non-Overlapping-Zone-Side-1      s-1-non-overlapping       32  1.10513145e-04          10.9369%
Non-Overlapping-Zone-Side-2      r-1-non-overlapping       33  1.10303113e-04          10.9179%
    Interface-Interior-Zone     intf:01-interior-1-1       31  8.99861833e-04          89.0546%
```

The `Area Percentage` for `intf:01-interior-1-1` is calculated as the area of `intf:01-interior-1-1` divided by the area of `s-1`.

- If you created one-to-one mesh interfaces, you can use the following text command to delete mesh interfaces that have a small area of overlap. You define the area percentage that is used for deletion: if the area that the two zones overlap divided by the area of the zone is less than this value for both zones in any mesh interface, then that mesh interface will be deleted. This can help you easily delete unnecessary or unintentional mesh interfaces.

  `define` → `mesh-interfaces` → `delete-interfaces-with-small-overlap`

14. For dynamic meshes, by default any motion is automatically transferred across a mesh interface when only one side is moving as a result of user-defined or system coupling motion, to ensure that the coupling is maintained on both sides. To change the method by which the displacement of the passive nodes is calculated or to disable this transfer altogether, use the `define/mesh-interfaces/transfer-motion-across-interfaces?` text command.

    With regard to the method by which the motion is transferred, you have two options: `transfer-displacements` (the default) interpolates nodal displacement from the active side of the interface to the passive side, and is recommended when there are gaps and/or penetrations in the mesh

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

interface that must be maintained; `project-nodes` projects the passive nodes onto the faces of active side, and is recommended when the active side undergoes significant tangential motion (as only the normal displacement is effectively transferred to the passive side in this method). For further details, see Transferring Motion Across a Mesh Interface (p. 1182).

Note:

For case files in which the interface was created in Ansys Fluent version 17.2 or earlier, you may reduce quality issues (such as left-handed faces) and/or convergence problems if you recreate the interface in version 18.0 or later by entering the following Scheme command in the console: (`recreate-sliding-interfaces`).

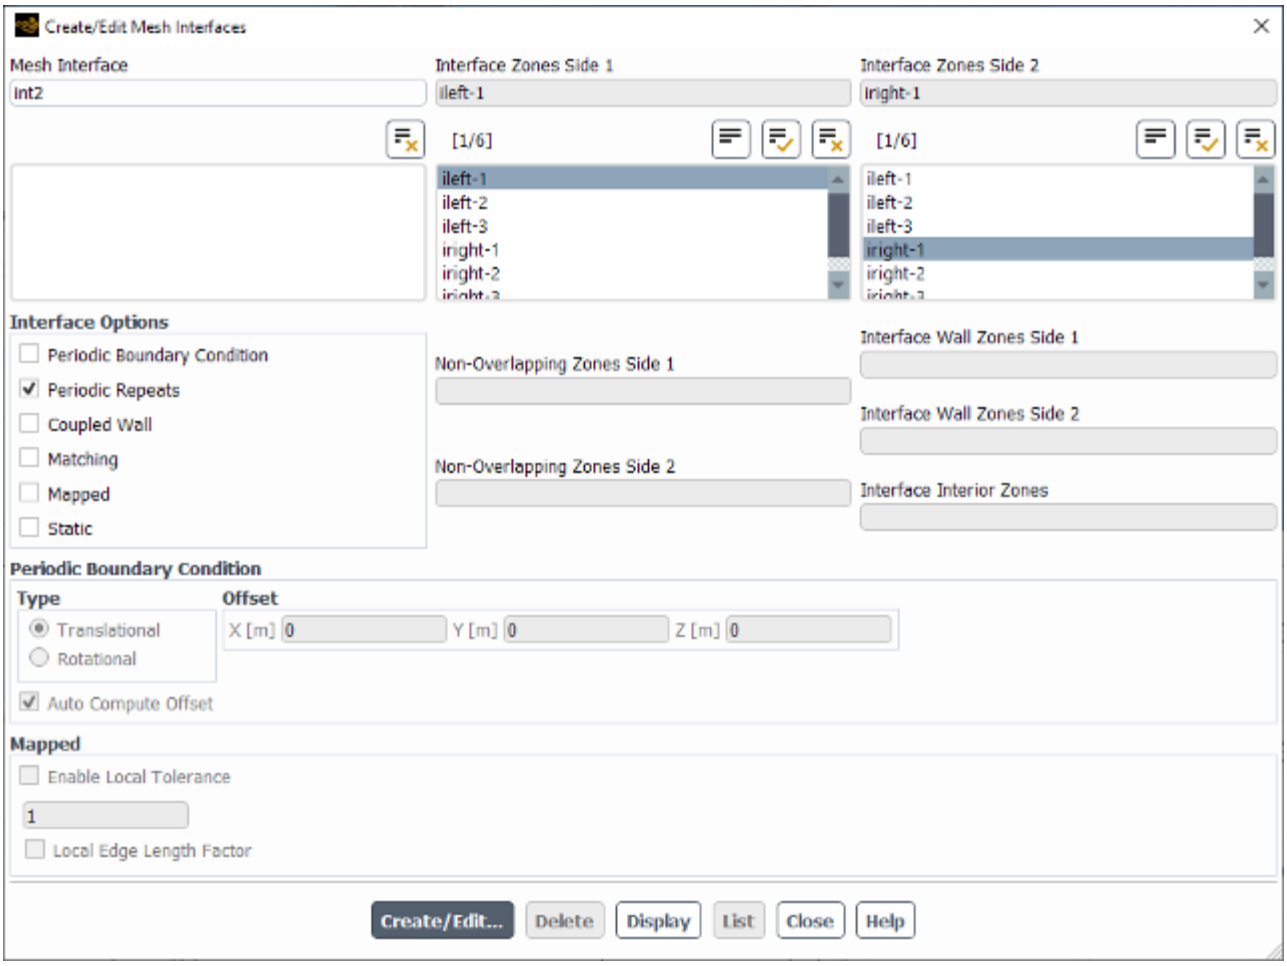
6.6.4.1. Manually Creating Mesh Interfaces

While it is possible to create every type of many-to-many mesh interface using the manual method, it is only necessary when you want your interface to use the periodic repeats option. If you want your interface to use the periodic option, you can create it manually or by using the **Create Periodic** dialog box (as described in Creating Periodic Zones and Interfaces (p. 1246)). For all other types it is more convenient to use the automatic method (as described in the preceding section), especially when you have many interface zones and/or are unfamiliar with their names / locations.

To manually create a mesh interface, you must ensure that the one-to-one interface creation method is disabled and then use the Create/Edit Mesh Interfaces Dialog Box (p. 5363), which is opened by clicking the **Manual Create...** button in the Mesh Interfaces Dialog Box (p. 5468).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.52: The Create/Edit Mesh Interfaces Dialog Box



1. Enter a name for the interface in the **Mesh Interface** text-entry box.

2. Specify the interface zones that make up the mesh interface by selecting one or more zones in the **Interface Zones Side 1** list and one or more zones in the **Interface Zones Side 2** list. Note that you must select only one zone per side if you plan to use the periodic or periodic repeats option.

3. Enable the desired **Interface Options**:

   - Enable **Periodic Boundary Condition** to create a non-conformal periodic boundary condition interface.

     – Select either **Translational** or **Rotational** as the periodic boundary condition **Type** to define the type of periodicity.

     – Retain the enabled default setting of **Auto Compute Offset** if you want Ansys Fluent to automatically compute the offset. After creating the interface, the offsets will be displayed in these fields. The fields will be uneditable when the **Auto Compute Offset** is enabled.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

– Disable **Auto Compute Offset** if you decide that you do not want Ansys Fluent to find the offset. In this case, you will have to provide the offset coordinates or angle in the required fields, depending on whether **Translational** or **Rotational** periodicity is selected.

Important:

→ Auto computation means that the rotational angle or the translational offset will be automatically calculated and used while creating a non-conformal periodic boundary condition interface. However, it still relies on the **Rotational Axis Origin** and the **Rotational Axis Direction** that was entered for the cell zone in the cell zone condition dialog box (for example, the **Fluid** dialog box). Therefore, before proceeding with the creation of the non-conformal periodic boundary condition interface, you have to correctly enter the rotational axis for the corresponding cell zone.

Note that auto computation of the non-conformal periodic boundary condition offset does not mean that the **Rotational Axis Origin** and **Rotational Axis Direction** are also detected automatically and updated. It is still your responsibility to set up these values correctly.

→ When using auto computation for 3D cases, you should ensure that the mesh resolution on the periodic interface zone pairs are similar if both of the following conditions are met: the periodic interface zone pairs are not planar; and they are not connected by at least two face zones that meet at an edge that points from one periodic zone to the other. In such situations, having a similar mesh resolution will produce more precise offset calculations (and subsequently, more accurate solutions). It is recommended that the average mesh size on one boundary should not be more than twice that of the other.

- Enable **Periodic Repeats** when each of the two cell zones has a single pair of conformal or non-conformal periodics adjacent to the interface (see Figure 6.35: Translational Non-Conformal Interface with the Periodic Repeats Option (p. 1154)). This option is typically used in conjunction with the sliding mesh model, when simulating the interface between a rotor and stator.

- Other options are available, as described in the preceding section. Note that with **Periodic Boundary Condition** enabled, the **Matching** option is also enabled by default and no other options are compatible; with **Periodic Repeats** enabled, only the **Coupled Wall** option is compatible.

4. Click **Create/Edit...** to create a new mesh interface. Ansys Fluent will automatically create additional wall and/or interior zones for the interface, which will appear under **Non-Overlapping Zones Side 1**, **Non-Overlapping Zones Side 2**, **Interface Wall Zones Side 1**, **Interface Wall Zones Side 2**, and **Interface Interior Zones**.

5. The buttons at the bottom of the dialog box allow you to take further actions, such as the following:

   - If you create an incorrect mesh interface, you can select it in the selection list and click the **Delete** button to delete it. Any additional wall and/or interior zones that were created when the interface was created will also be deleted.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- To edit an interface, select it in the selection list and click **Create/Edit...**, and then revise the settings using the Edit Mesh Interfaces Dialog Box (p. 5398) that opens.

- You can click the **Display** button to display interface zones or mesh interfaces in the graphics window. Note that you can only select and display interface zones from **Interface Zones Side 1** or **Interface Zones Side 2** if no interfaces are selected in the selection list and if the zone in question is not yet assigned to an interface. After an interface is defined, you can select the appropriate mesh interface and click the **Display** button to display the zones under **Interface Zones Side 1** and **Interface Zones Side 2** together. Displaying is particularly useful if you want to check the location of the interface zones prior to setting up a mesh interface.

6.6.4.2. Transferring Motion Across a Mesh Interface

Ansys Fluent allows motion to be specified on either side of a mesh interface, and in some instances, can transfer the motion from one side of a mesh interface to the other. When motion is specified on one side of the interface (but not on the other) using either User-Defined Motion (p. 1881) or System Coupling Motion (p. 1884), by default Ansys Fluent will automatically interpolate and transfer this motion so that the coupling is maintained on both sides. To disable this transfer or change the method by which the displacement of the nodes on the passive side is calculated, use the following text command:

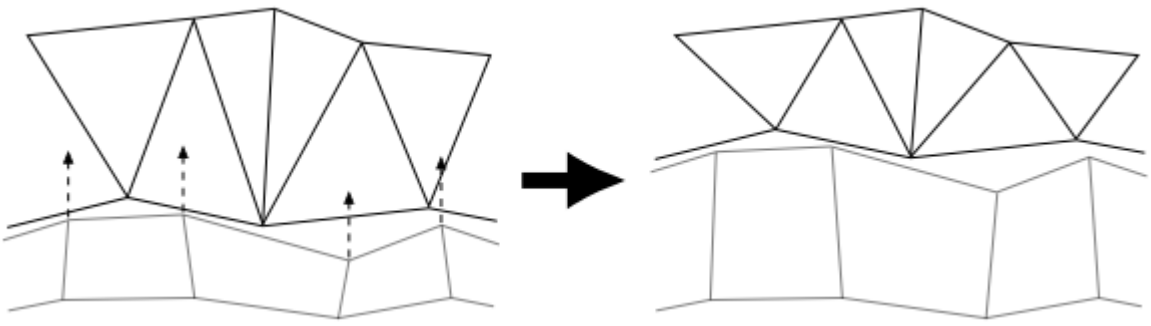
`define` → `mesh-interfaces` → `transfer-motion-across-interfaces?`

When such transfer is disabled, the sides of the mesh interface may separate and/or penetrate over the course of the simulation, which may lead to convergence difficulties and/or an invalid mesh. When it is enabled, you have the following options:

- the `transfer-displacements` approach (default)

  This approach interpolates nodal displacement from the active side of the interface to the passive side; it uses an inverse-distance weighted interpolation, so that the closer active nodes have more influence. This may be beneficial in situations where gaps and/or penetrations are present at the interface, and they need to be maintained as the simulation progresses. Note that any motion specified tangential to the interface will also be interpolated to the passive side, which can lead to unintended mesh dragging.

  Figure 6.53: Transferring Displacements

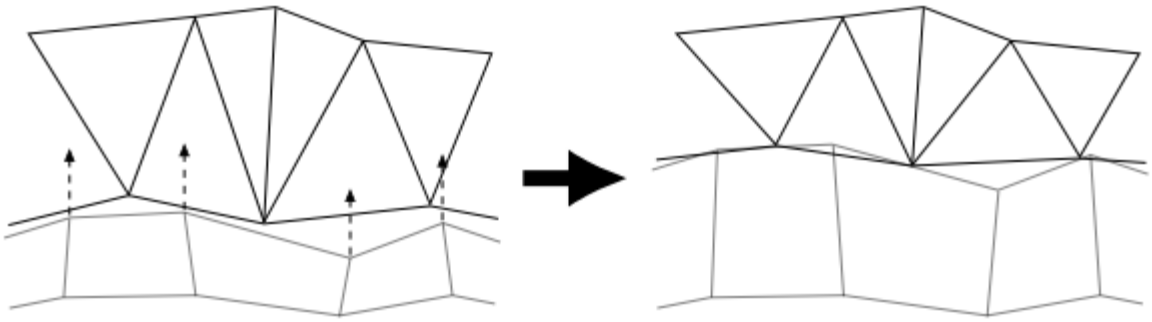


- the `project-nodes` approach

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This approach projects the nodes of the passive side of the interface onto the faces of the active side, in order to maintain conformity. It is beneficial in situations that involve significant tangential motions on the active side of the interface, as only the normal displacement is effectively transferred to the passive side. Note that for mesh interfaces that involve significant gaps or penetration, the `project-nodes` approach may cause the mesh to become invalid.

Figure 6.54: Projecting Nodes



Note:

If you expect the motion to produce large displacements, you should consider applying a mesh update method on the cell zone of the passive side (such as smoothing or remeshing, as described in Dynamic Mesh Update Methods (p. 1784)).

6.7. Overset Meshes

Fluent allows you to build up the computational domain from overlapping meshes—also known as Chimera or overset methodology. This gives you another way to build the complete mesh, in addition to using conformally connected cell zones and non-conformal interfaces.

6.7.1. Introduction

6.7.2. Overset Topologies

6.7.3. Overset Domain Connectivity

6.7.4. Diagnosing Overset Interface Issues

6.7.5. Overset Mesh Adaption

6.7.6. Overset Meshing Best Practices

6.7.7. Overset Meshing Limitations and Compatibilities

6.7.8. Setting up an Overset Interface

6.7.9. Postprocessing Overset Meshes

6.7.10. Writing and Reading Overset Files

6.7.1. Introduction

Whereas non-conformal interfaces connect cell zones along matching face zones, overset interfaces connect cell zones by interpolating cell data in the overlapping regions. For overset meshing to be successful, the cell zones must overlap sufficiently. An advantage of overset meshing is that the indi-

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

vidual parts of an overset mesh can be generated independently and with fewer constraints than if the parts had to fit together conformally or along non-conformal interfaces. This can make it easier to replace parts of a mesh without having to remesh large parts or even the complete mesh.

Figure 6.55: Overset Component and Background Mesh

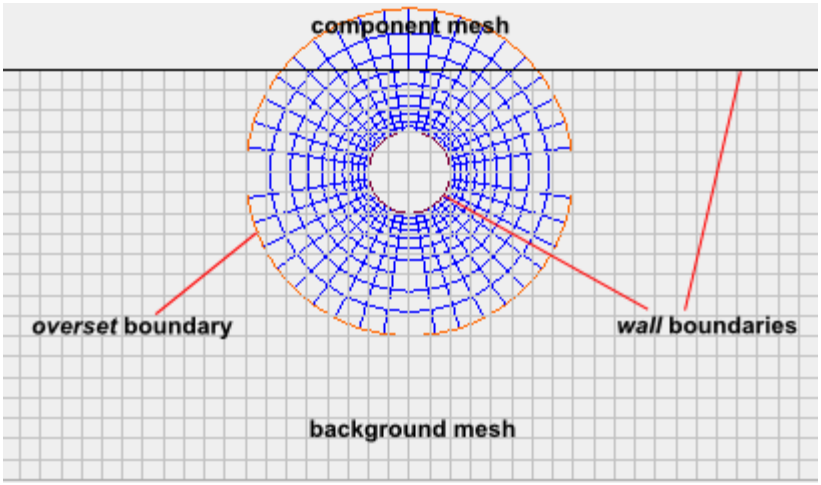


Figure 6.55: Overset Component and Background Mesh (p. 1184) shows a simplified mesh for a simulation of flow over a cylinder in a duct. The mesh consists of two parts—a *background* mesh representing the duct and a separate *component* mesh around the cylinder. The case is set up in Fluent as an overset case by specifying the outer boundary of the cylinder mesh as **overset** (boundary type), and by creating an overset interface containing the two cell zones. With these two steps complete, Fluent automatically establishes the necessary connectivity between the meshes when the flow is initialized. In this process, cells that fall outside the computational domain are classified as *dead* cells. The cells where the flow equations are solved are referred to as *solve* cells. *Receptor* cells receive data interpolated from another mesh. The *donor* cells—the cells where the receptors get their data—are a subset of the solve cells. For the above case, Figure 6.56: Solve Cells After Initialization (p. 1184) shows the solve cells of the mesh after the flow is initialized. Note that in parallel, you can print partition statistics to get information about some of the cell classifications, as described in Interpreting Partition Statistics (p. 4305).

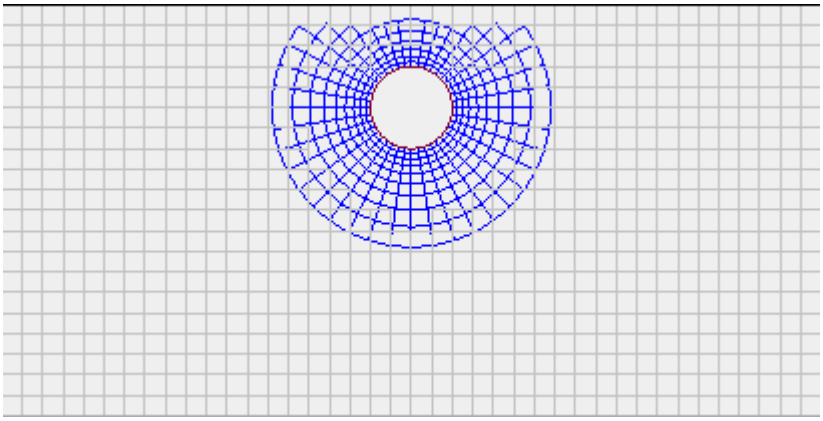
Figure 6.56: Solve Cells After Initialization



There is no limit on the number of cell zones that can be paired in an overset interface. Fluent classifies the cell zones in an overset interface as either *background* or *component*:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Background zones are the cell zones that make up the background mesh of the computational domain. Background zones cannot have **overset** boundaries.
- Component zones overlay background zones and have **overset** boundaries near where they connect to the background and other component zones. If multiple component zones are connected, at least one of these zones needs to have an overset boundary.

All cell types generally supported in Fluent are supported with overset meshing, including polyhedral cells in 3D. The different zones paired in an overset interface can have different element types or can have mixed element types.

Overset meshing in Fluent is compatible with mesh adaption. The mesh zones of an overset interface can be locally adapted using all available adaption tools.

Overset meshing can be used for steady-state or transient solutions. Note that for steady-state cases in parallel that use the default **Metis** partitioning, Ansys Fluent will automatically repartition overset meshes when the solution is initialized or data is read; a model-weighted partitioning that is designed for optimal performance is used.

6.7.2. Overset Topologies

There are a multitude of configurations that can be constructed by superposing background and component meshes in an overset interface. Fluent analyzes the topology of an interface with minimal user input, which requires that the superposed meshes adhere to some topological constraints.

A case can have multiple overset interfaces, but a cell zone can only belong to a single interface. That is, interfaces cannot share component or background meshes. It is always possible to have a single overset interface for an entire model. However, it is more efficient to declare multiple interfaces if the zonal topology allows it. Only including cell zones that are absolutely required in an interface also increases efficiency.

In general, most overset interfaces will have at least one background and one component mesh. However, Ansys Fluent also allows you to set up overset interfaces that have no background mesh and consist only of two or more component meshes.

An overset interface can contain multiple component and background meshes, provided that the background meshes do not intersect each other.

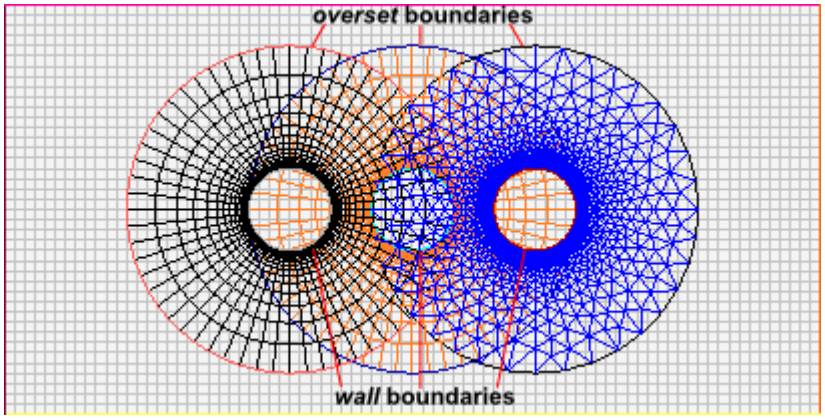
Currently, non-conformal interfaces are not fully compatible with overset meshing. Non-conformal mesh interfaces are permissible inside overset cell zones if the mesh interface boundaries do not spatially overlap with where the active overset interface lies. The proximity between the mesh interfaces and overset interfaces is checked during initialization and when the overset interfaces are updated. A warning is issued and the mesh check will fail if not enough separation is detected between the interfaces.

The component meshes of an overset interface are allowed to overlap arbitrarily and multiple component meshes can be combined to create an object of interest. However, an important topological constraint is that physical boundary zones (wall, inlet, outlet, symmetry, and so on) are not allowed to *intersect* each other. That is, a wall boundary cannot cross another wall boundary. For example, in the model shown in Figure 6.55: Overset Component and Background Mesh (p. 1184), the component mesh cannot be placed such that its wall boundary zone intersects with the wall of the background mesh.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

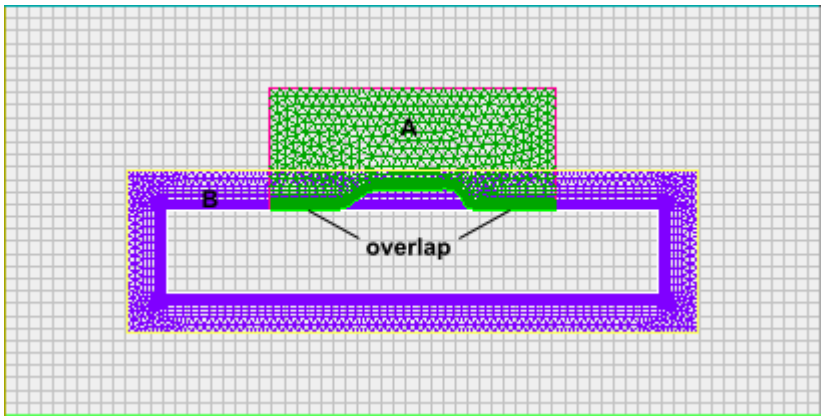
Overset boundaries can intersect with other overset boundaries and with physical boundaries. In Figure 6.55: Overset Component and Background Mesh (p. 1184) the overset boundary of the component mesh extends outside of the intended computational domain, crossing the wall boundary of the background mesh—this is allowed. Figure 6.57: Valid Overset Meshes with Components in Close Proximity (p. 1186) shows a valid configuration of three cylinders in proximity (none of the physical boundaries intersect with other physical boundaries).

Figure 6.57: Valid Overset Meshes with Components in Close Proximity



Physical boundary zones are allowed to *overlap*, that is, a wall boundary (or parts of a wall boundary) can be coincident with another wall boundary, as long as they do not cross. This powerful functionality lets you build a body from overlapping parts or modify a body by adding parts. Figure 6.58: Second Component Modifying Existing Body (p. 1186) shows an overset configuration where a second component mesh is added to an existing body to modify its shape. Fluent analyzes and automatically detects the overlapping boundaries (walls in this case) of the different meshes in an overset interface, when deciding which cells are solve cells and which cells are dead cells.

Figure 6.58: Second Component Modifying Existing Body

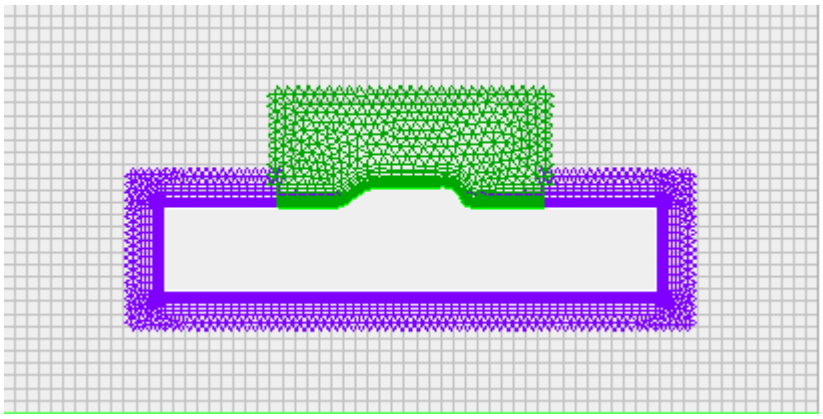


*Note that part of the wall boundary of mesh **A** lays on top of part of the wall boundary of mesh **B**, overlapping it, but the walls do not cross or intersect.*

Figure 6.59: Existing Body Modification After Initialization (p. 1187) shows the solve cells of the mesh after the flow field is initialized.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.59: Existing Body Modification After Initialization



The previous example shows a case where physical boundaries overlap between two component meshes. Overlapping boundaries can also exist between component and background meshes.

If a body can only be built from components that have intersecting boundaries, then you must use a *collar* mesh to properly connect them. A collar mesh is an additional component mesh that bridges the intersecting physical boundaries, essentially transforming the intersection problem (not allowed) into a problem of overlapping boundaries (allowed). Figure 6.60: Multiple Components Bridged by Collars Meshes (p. 1187) shows an overset interface consisting of two component meshes that have intersecting wall boundaries. Two collar meshes (labeled **C** and **D**) are manually created to correctly define the connectivity where the wall boundaries of the original component meshes (labeled **A** and **B**) intersect. The wall boundaries of meshes **C** and **D** overlap with the wall boundaries of meshes **A** and **B**.

Figure 6.60: Multiple Components Bridged by Collars Meshes

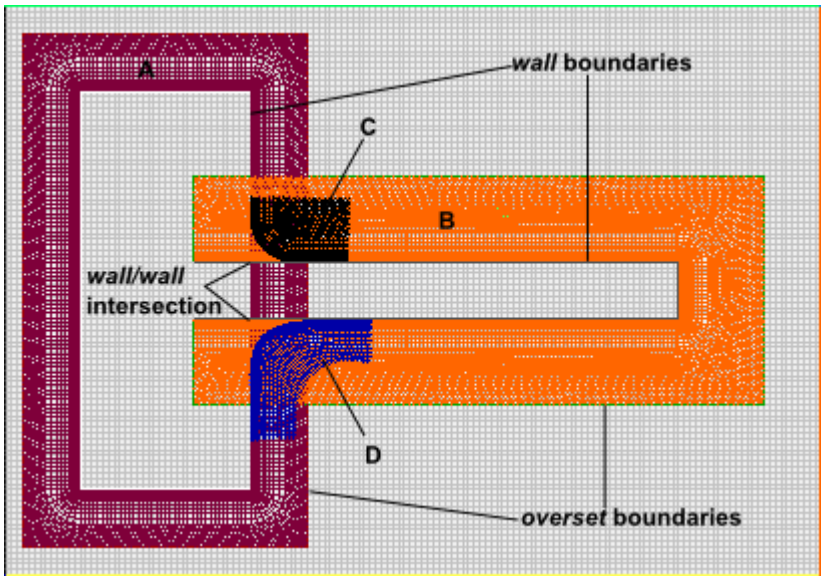


Figure 6.61: Multiple Components with Collar Meshes Initialized (p. 1188) shows the resulting solve cells after the flow is initialized. The collar meshes act as fillet meshes that place the actual boundary intersections into the interior of the body and outside of the fluid domain.

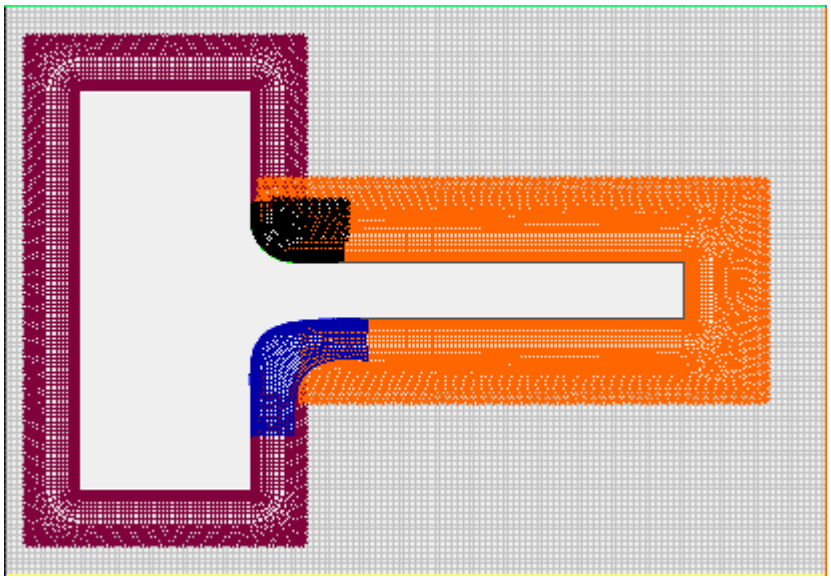
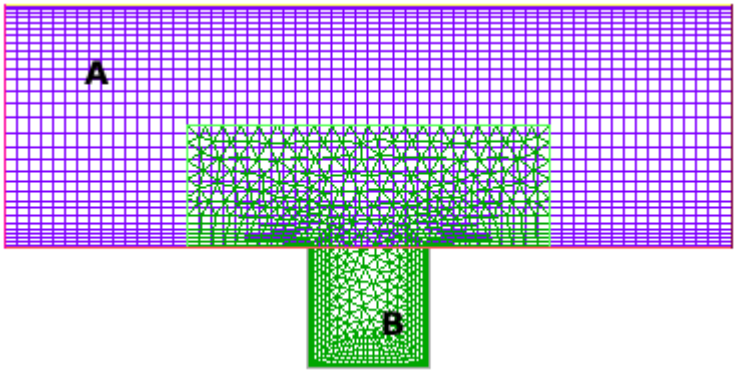
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.61: Multiple Components with Collar Meshes Initialized



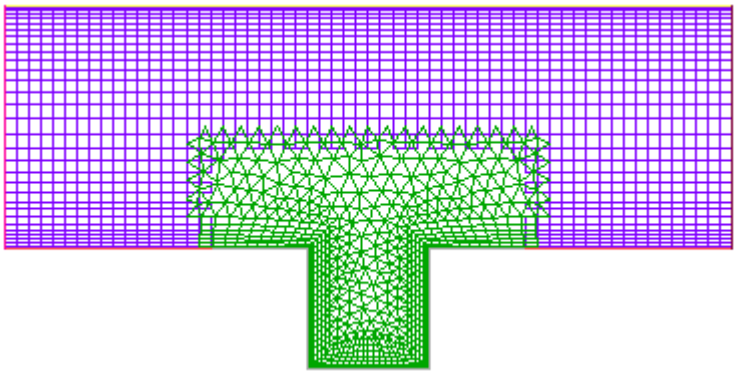
Special considerations are required when you intend to add a fluid region that expands the bounds of an existing region, as shown in Figure 6.62: Adding Fluid to a Region Using Cut Control (p. 1188). In this example, a duct (**A**) is modified by adding a cavity (**B**). The boundaries of the two meshes intersect, and by default the lower boundary of the duct would cut off the added cavity. In order to avoid this, you need to use cut control to specify that the duct wall is not cutting the cavity cell zone, and, similarly, that the cavity boundary is not cutting into the duct cell zone. See Hole Cutting Control (p. 1190) for details on the available cut controls. The resulting mesh for the duct / cavity example after initialization is shown in Figure 6.63: Cut Controlled Region After Initialization (p. 1189).

Figure 6.62: Adding Fluid to a Region Using Cut Control



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.63: Cut Controlled Region After Initialization



Baffles (coupled walls) are permissible in overset meshing—both in background and component meshes.

6.7.3. Overset Domain Connectivity

When an overset interface is initialized, there are three main steps that Fluent completes to establish connectivity between the participating zones:

6.7.3.1. Hole Cutting

6.7.3.2. Overlap Minimization

6.7.3.3. Donor Search

6.7.3.1. Hole Cutting

Hole cutting is the process by which cells lying outside of the flow region (that is, inside bodies and outside of the computational domain) are marked as dead cells. This is achieved by marking all the cells that are cut by physical boundary zones (wall, inlet, outlet, symmetry, and so on), and marking seed cells determined to lie outside the flow region for subsequent flood filling of dead cells. The result of this flood filling is a valid overset mesh with maximum mesh overlap.

Figure 6.64: Overset Component and Background Meshes Before Hole Cutting (p. 1190) and Figure 6.65: Overset Component and Background Meshes After Hole Cutting (p. 1190) show an overset mesh before and after hole cutting. All of the background cells that are bounded or cut by the cylinder wall are classified as dead during hole cutting. The maximum overlap mesh shown in Figure 6.65: Overset Component and Background Meshes After Hole Cutting (p. 1190) is a valid overset mesh, however, it may not be ideal. An overly large overlap between component and background meshes is computationally inefficient (the equations are solved in more cells than are necessary). Additionally, the cell sizes of the overlapping meshes may vary greatly—this affects the data interpolation and is detrimental to solution quality. Ideally meshes should transition in regions of similar resolution.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.64: Overset Component and Background Meshes Before Hole Cutting

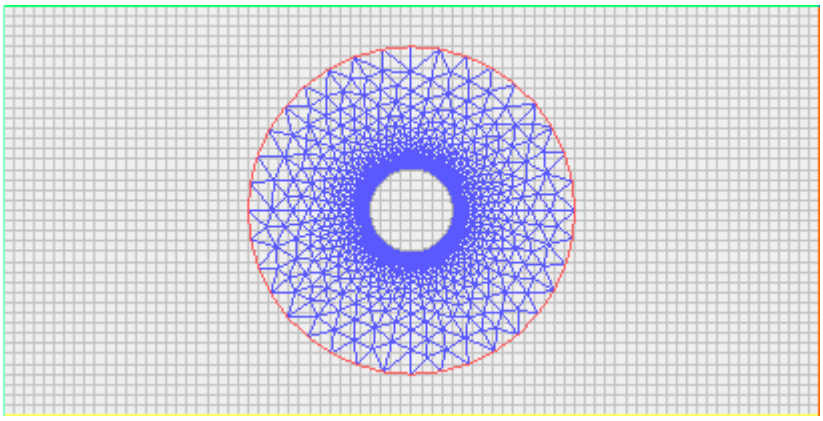


Figure 6.65: Overset Component and Background Meshes After Hole Cutting

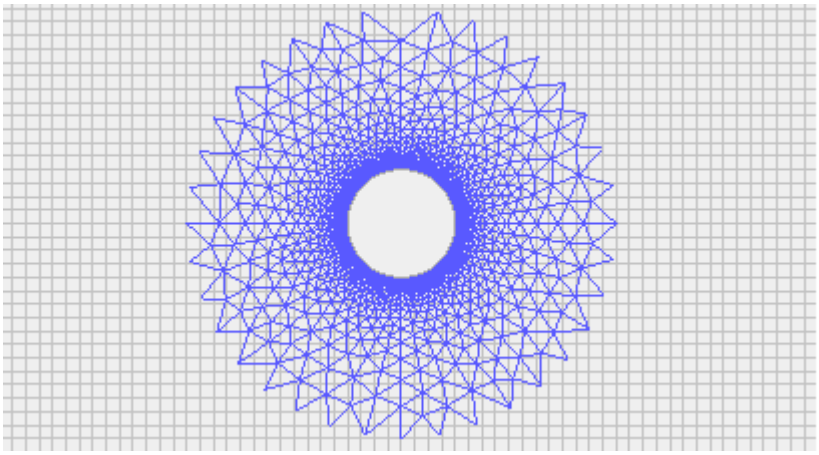


6.7.3.1.1. Hole Cutting Control

By default all boundary zones (other than overset boundaries) cut all other cell zones and mark dead cells. If this is not the desired behavior (see Overset Topologies (p. 1185)), you can manually specify that a boundary zone does not cut certain cell zones. This optional cut control is available using the following text command:

`define` → `overset-interfaces` → `cut-control` → `add`

A component mesh with only overset boundaries (for example, a refinement mesh zone overlaying other zones) will cut into other mesh zones at its center and mark a single dead cell (cut seed) in the overlaying mesh zones. This acts as a pilot hole that is then enlarged during the overlap minimization. In cases where all cut boundaries of a component mesh are overlapping with other boundaries, you can force cut seeds in all component zones using the following text command:

`define` → `overset-interfaces` → `cut-control` → `cut-seeds` → `cut-seeds-for-all-component-zones?`

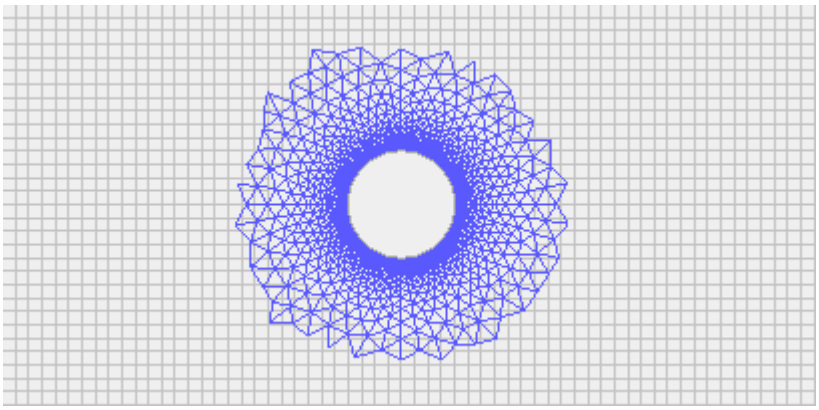
Cut seeds are automatically enabled for all component zones when a cut control is added.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.7.3.2. Overlap Minimization

Overlap minimization is used to minimize mesh overlap among different component and background meshes by converting additional solve cells into receptor cells and turning unnecessary receptors into dead cells. During this process, a solve cell is turned into a receptor cell if the cell can find a suitable donor cell with higher donor priority. By default, smaller cells have a higher donor priority. Thus, in mesh overlap areas, without additional user input the solver attempts to obtain the solution on the finest local mesh. The resulting mesh interface moves to an area where the meshes are more comparable in cell size, leading to better solution quality. Figure 6.66: Overset Component and Background Meshes After Overlap Minimization (p. 1191) shows the cylinder case from the previous figure after the overlap minimization step.

Figure 6.66: Overset Component and Background Meshes After Overlap Minimization



Note that overlap minimization is not literally minimizing the mesh overlap. The overlap minimization is based on a flood filling of receptor cells, wherever suitable solve cells with higher donor priority can be found. The resulting actual mesh overlap depends on the local donor priority distribution.

Also note that with overlap minimization, data interpolation between cell zones does not necessarily occur at the overset boundaries. The purpose of specifying an overset boundary is primarily to specify that overset mesh coupling should happen, and not where it should occur.

You have the option to specify different donor priority methods in order to control the location of the overset interface. The text user interface command `define/overset-interfaces/options/donor-priority-method` allows you to specify that the donor priority is based either on the cell size (proportional to the inverse of the cell volume) or the boundary distance (proportional to the inverse of the distance to the closest boundary). Overlap minimization with donor priority based on cell size (default) works best if the component mesh resolution is fine near walls and increases away from walls, to spacings similar to—or larger than—the background mesh (see Figure 6.64: Overset Component and Background Meshes Before Hole Cutting (p. 1190) for an example of this type of mesh). If the overlapping meshes have uniform and nearly identical resolutions, then overlap minimization based on cell size will not reduce the overlap and a donor priority based on the boundary distance should be used instead. The following two figures illustrate an overset mesh before and after initialization where a donor priority based on boundary distance is used. Note that for the evaluation of donor priorities based on boundary distance, all boundaries (including inlets, outlets, and so on) are used for the distance evaluation.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.67: Overset Mesh Before Hole Cutting

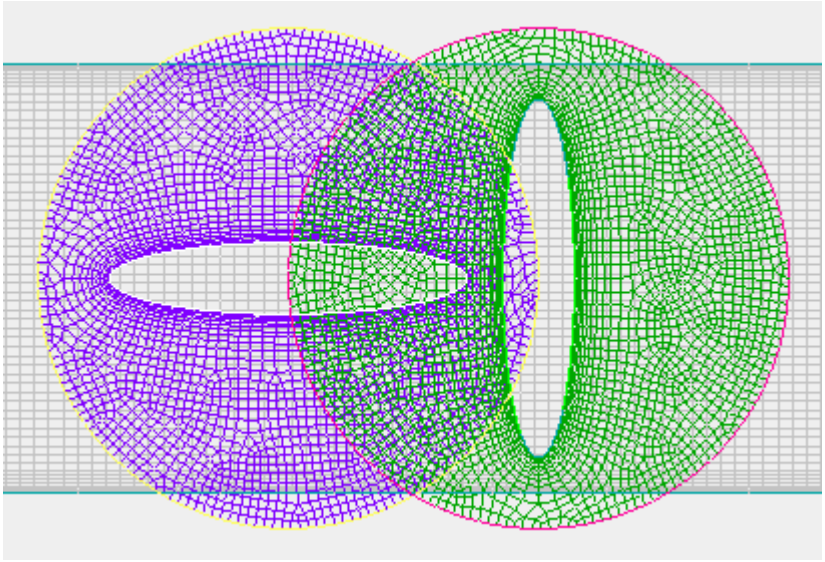


Figure 6.68: Overset Mesh After Minimization Based on Boundary Distance

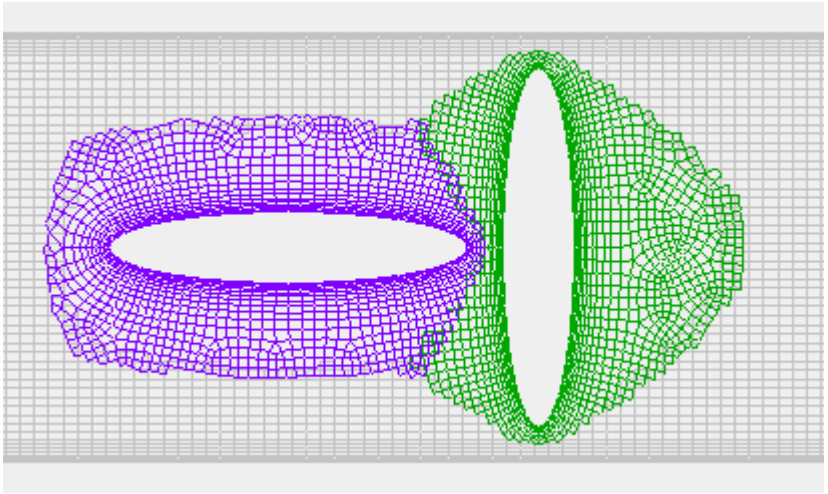


You have the option for additional control over the overlap minimization process by assigning grid priorities to component and background meshes, using the text user interface command `define/overset-interfaces/grid-priorities`. Meshes (that is, cell zones) with higher grid priorities are favored during the minimization process, irrespective of the local cell donor priority. If two cell zones have the same grid priority, then the cell donor priorities are used for the overlap minimization. For example, by assigning a higher grid priority to a coarser mesh, you can force Fluent to minimize the finer mesh and obtain the solution on the coarser mesh, even if the donor priority is based on cell size. Using grid priorities, similar to using donor priority based on boundary distance, is helpful if local mesh distributions are irregular, and produce overlap regions that are irregular as well. Note that the grid priorities take precedence over the donor priorities.

You have the option of disabling overlap minimization by using the text command `define/overset-interfaces/options/minimize-overlap?`. This command is only available globally and applies to all overset interfaces in the domain.

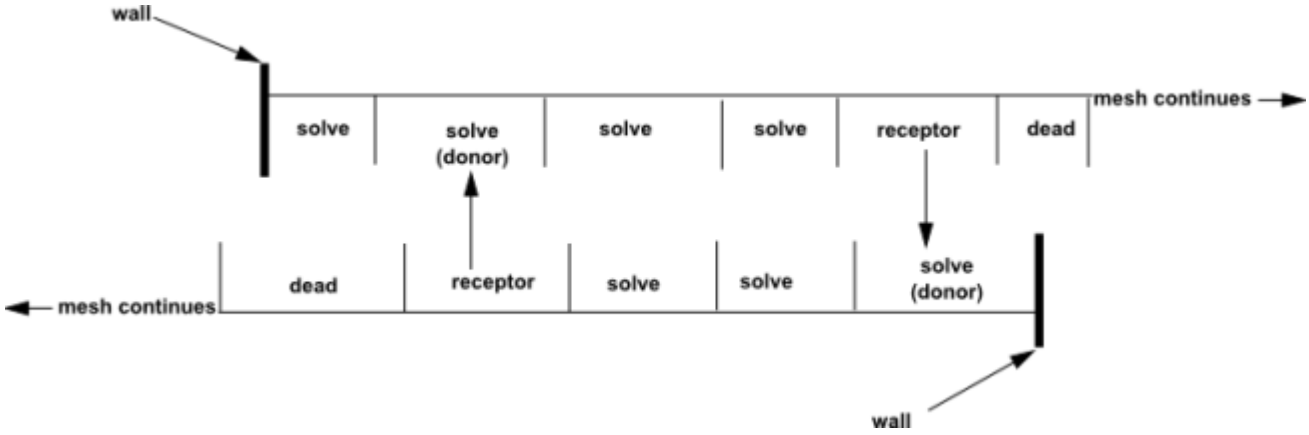
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.7.3.3. Donor Search

The donor search is the final step in establishing the domain connectivity. Fluent searches other meshes for valid solve cells for each receptor. The solve cell containing the cell centroid of the receptor cell, along with its connected solve cells, are used as donor candidates for a given receptor. Each receptor must have at least one valid donor cell.

There must be four or more cells in the overlap of both meshes to ensure a successful donor search. The receptor cells, which form the fringe layer of a mesh zone, must overlap sufficiently with the opposite mesh, such that they find valid solve cells as donors. For an example of valid mesh overlap, see Figure 6.69: Valid Overlap (p. 1193).

Figure 6.69: Valid Overlap



6.7.4. Diagnosing Overset Interface Issues

Topology detection of overset interfaces in Fluent is automatic and does not require user input. However, for it to work well, it requires that the provided meshes are of sufficient quality, particularly when dealing with meshes that have overlapping boundaries.

Overset meshes are built from parts that can be meshed independently, which can lead people to think of this as a much simpler process for mesh generation. This is not always the case, as considerable thought is often required to generate good meshes for the individual components to avoid problems during overset interface initialization.

If you are faced with issues during the initialization of an overset interface, there is most often no recovery without making changes to the mesh. You must analyze the cause of the issue, using the available postprocessing and diagnostic tools, and improve the mesh before the simulation can continue.

When diagnosing overset interface failures, it can be convenient to use the text commands `define/overset-interfaces/intersect` and `define/overset-interfaces/clear` (available after enabling the expert tools available under `define/overset-interfaces/options/expert`?) to execute and clear the hole cutting without having to initialize the solution.

The issues most often encountered are:

6.7.4.1. Flood Filling Fails During Hole Cutting

6.7.4.2. Donor Search Fails Due to Orphan Cells

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.7.4.1. Flood Filling Fails During Hole Cutting

These are the issues that can cause problems with flood filling:

6.7.4.1.1. Incorrect Seed Cells

6.7.4.1.2. Leakage Between Overlapping Boundaries

6.7.4.1.1. Incorrect Seed Cells

Flood filling of dead cells will fail if Fluent inadvertently identifies seed cells inside of the fluid zone instead of outside. This can occur as a result of complexities in the topology or geometry of the boundary zones, or because of mesh resolution issues. It manifests itself as an entire fluid region, or a complete cell zone, being marked as dead.

This issue can be diagnosed by using the list command with the overset verbosity set to `1` (see Overset Interface Listing (p. 1210)).

You can use the TUI command `define/overset-interfaces/debug-hole-cut` (available after enabling the expert tools available under `define/overset-interfaces/options/expert?`) to identify the problematic seed cells. This command allows you to execute the hole cutting process on a specific overset interface and mark dead and seed cells.

When the flood fill option of the debug command is disabled, it will create two registers with dead cells and seed cells which you can then display using the `define/overset-interface/display-cells` text command. The dead marks show the cells cut by the physical boundary zones. The seed cells (mark0 register) show the cell candidates that will be used for flood filling.

If the flood fill option of the debug command is enabled, Fluent will then also create a register of the seed cells from where flood filling actually started (mark1 register). If flood filling fails, displaying these mark1 cells is the most efficient way to detect the problematic locations in the model.

It is critical that all the seed cells are located inside bodies or outside of the computational domain. If there is a seed cell in the fluid region, it will cause a flood fill failure. It is not possible to recover from flood filling failure without making changes to the model.

6.7.4.1.2. Leakage Between Overlapping Boundaries

If no bad seed cells are found, as described in Incorrect Seed Cells (p. 1194), and there are overlapping boundaries, it is likely that the overlapping boundaries do not match sufficiently and the flood filling of dead cells leaks from the inside of the body to the outside. As a result, a complete cell zone can disappear, due to having only dead cells. The permissible tolerance between overlapping boundary zones is at most one cell-size in the wall normal direction. This can be restrictive when dealing with prismatic boundary layer meshes with high cell aspect ratios at the wall. If your model suffers from this leakage, you generally need to improve the quality of the mesh, by making the overlapping boundary zones match better.

6.7.4.2. Donor Search Fails Due to Orphan Cells

If a receptor cell cannot find a valid donor cell, then it becomes an *orphan* cell. The presence of orphan cells generally indicates that there is insufficient overlap between meshes or that the mesh

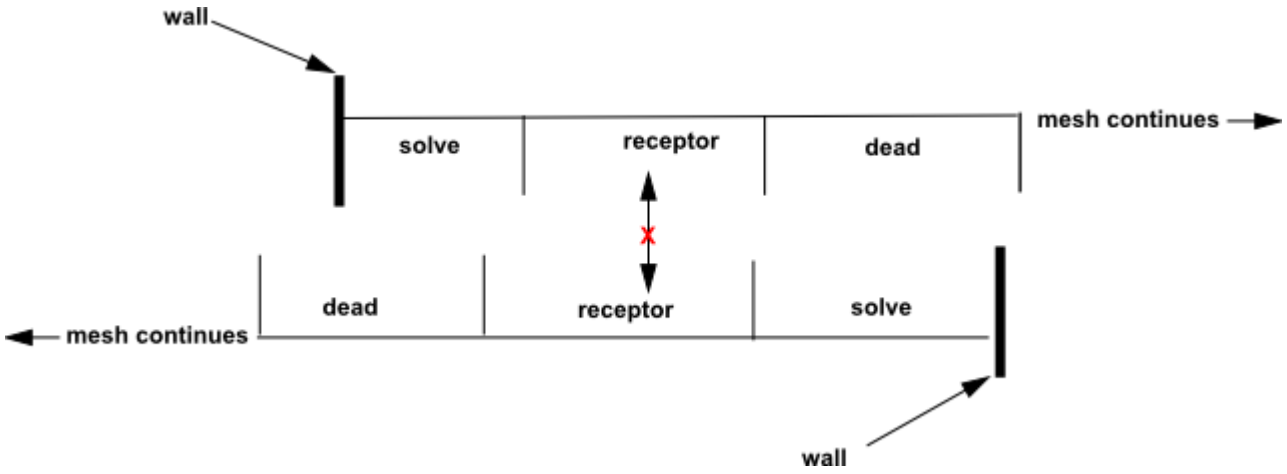
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

resolutions do not match well. As a result, the receptors are either finding no candidate donor cells, or invalid candidates (dead or receptor cells).

Orphan cells can be an issue when walls of different meshes are in proximity. You must have at least four cells in a gap, such as the ones between the walls in Figure 6.57: Valid Overset Meshes with Components in Close Proximity (p. 1186), in order to have a good connection between the meshes—otherwise orphan cells are created. When a receptor overlays another receptor, it becomes an orphan.

See Figure 6.70: Invalid Overlap Creating Orphans (p. 1195) for an example of insufficient overlap causing the creation of orphan cells. For information on visualizing orphan cells, see Postprocessing Overset Meshes (p. 1206). Figure 6.69: Valid Overlap (p. 1193) shows meshes overlapping sufficiently to avoid the creation of orphan cells.

Figure 6.70: Invalid Overlap Creating Orphans



You can mark the orphan cells, as described in Overset Cell Marks (p. 1210), which will likely indicate where the mesh overlap must be increased. Sometimes, increasing the mesh resolution can lead to a sufficient increase in mesh overlap. If mesh resolution is the issue, you can also use local mesh adaption, along with mesh modification, to refine the mesh. Most often the mesh requiring adaption is the mesh where the orphan should find its donors, and not the mesh zone containing the orphan. For details on overset-specific adaption tools in Fluent, see Overset Mesh Adaption (p. 1195).

If the presence of orphan cells in the simulation is unavoidable and you proceed with a calculation, by default the solver applies a numerical treatment that attempts to assign reasonable values to the orphan cells. This treatment has been found to prevent divergence in some instances, allowing the solution to proceed; however, the orphan cell treatment does not guarantee the solution quality and robustness a priori. The success of this treatment is case dependent, and difficult to predict based on orphan cell counts. It is therefore highly recommended that you make every effort to eliminate orphan cells by modifying the mesh, as described previously.

6.7.5. Overset Mesh Adaption

Fluent has functionality that allows you to attempt to remove orphan cells, reduce size mismatches between donor and receptor cells, and/or increase the mesh resolution in gaps as needed (in order to prevent the creation of orphan cells) by locally refining the mesh. These are overset-specific adaption tools that analyze the initialized overset interface and can perform marking and adaption of cells in a single step.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

It is important to note that there are different reasons for the existence of orphan cells, and that not all orphans can be removed by locally refining the mesh. Overset adaption will proceed iteratively, up to a maximum of five adaption cycles: cells are marked at the start of each cycle, and by default two sweeps of adaption are applied during each cycle. Multiple adaption sweeps are performed for a given set of adaption markings in order to reduce the time taken for the adaption process. The overset interface needs to be reestablished after each adaption cycle, which can be computationally costly. In cases where mesh resolution is the reason for orphans, this adaption process should effectively improve the mesh and reduce the orphan count.

Overset mesh adaption can be used to improve the mesh either manually on demand, or automatically for moving and dynamic mesh simulations. If automatic overset adaption is enabled, then the mesh is marked and adapted automatically at every time step after the mesh update. Since it is computationally costly to establish the overset connectivity at the end of each adaption cycle, Fluent performs only a single cycle during automatic overset adaption. Thus, a single automatic overset adaption step may not be as thorough in removing orphan cells as an instance of manual adaption; however, automatic overset adaption will be executed at every time step if orphan cells persist.

6.7.5.1. Marking for Orphan Adaption

For each orphan, all of the cells in the overlapping meshes that bound the orphan's cell centroid are marked for adaption; by default, an additional buffer layer of cells surrounding those bounding cells are also marked. The mesh zone that contains the orphan cell is not marked for adaption.

6.7.5.2. Marking for Size Adaption

Excessively large donor cells are marked for adaption if the ratio of the donor cell volume (V_d) divided by its smallest receptor cell volume (V_r) exceeds a limit. This limit is controlled by a maximum length scale ratio R_l. Donor cells with a V_d / V_r value greater than R_l^3 in 3D and greater than R_l^2 in 2D are marked for adaption. The default value for R_l is 3.

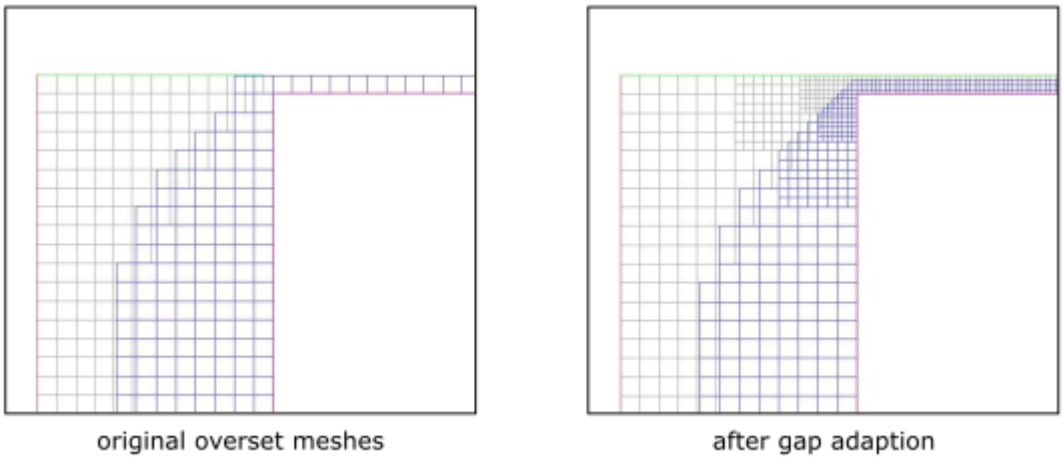
After initialization, the value for V_d / V_r can be postprocessed by selecting the **Overset Donor Size Ratio** field variable (under the **Mesh...** category).

6.7.5.3. Marking for Gap Adaption

For overset meshes, it is recommended that the gaps between walls are resolved by a minimum of 4 cells, in order to create a valid overset interface and prevent the creation of orphan cells. You can specify that the cells in gaps with a resolution that is less than this recommendation (or another gap resolution value of your choice) are marked for adaption, so that any subsequent overset adaption (manual or automatic) increases the resolution to meet or exceed the gap resolution value. Note that marking cells for gap adaption is not enabled by default, but can be enabled as described in Overset Adaption Controls (p. 1198).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.71: Overset Gap Adaption



6.7.5.4. Using Manual Overset Adaption

Overset adaption can be applied manually on demand in order to improve the mesh. Typically it is used in steady simulations or simulations without mesh motion.

The overset mesh is marked and adapted in a single step using the following text command:

`define` → `overset-interfaces` → `adapt` → `adapt-mesh`

You can perform just the marking step for overset adaption by entering the following text command: `define/overset-interfaces/adapt/mark-adaption`. Note that it is not necessary to perform this marking step before using the command to adapt; the purpose of such marking is primarily to verify the adaption parameters and evaluate whether they need to be changed. The text command to mark for adaption will mark cells (mark0 for orphan adaption, size adaption, and gap adaption, and mark1 for coarsening), so that you can then create cell registers and thereby postprocess them as described in Overset Cell Marks (p. 1210). Note that mark0 and mark1 are only available after enabling the expert tools through the following text command: `define/overset-interfaces/options/expert?`.

You can use the following text command to set a verbosity level of 2 if you want to print the number of cells marked for refinement in the console when the overset mesh is adapted: `define/overset-interfaces/options/verbosity`.

6.7.5.5. Using Automatic Overset Adaption

With moving and dynamic mesh simulations, it can be difficult to create an initial mesh that meets all of the needs throughout the simulation while also being computationally efficient. Rather than refining the initial mesh in regions that only require such refinement temporarily, it can be preferable to use automatic overset adaption so that Fluent analyzes the mesh at every time step and then refines or coarsens the cells as required; the goal is to remove orphans and/or reduce size mismatches between donor and receptor cells.

To enable automatic overset adaption, you can use the Automatic Mesh Adaption Dialog Box (p. 5348) as described in Overset Adaption (p. 3779), or you can use the following text command:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

`define` → `overset-interfaces` → `adapt` → `set` → `automatic?`

Automatic overset adaption is fully compatible with conventional automatic mesh adaption, such as when it is used to more accurately track Volume of Fluid (VOF) interfaces (as described in VOF Adaption (p. 3775)). The two adaption methods can be enabled at the same time, and will not interfere with each other.

6.7.5.6. Overset Adaption Controls

If the default settings for overset adaption are not suitable for your case, you can revise them using the text commands in the following menu:

`define` → `overset-interfaces` → `adapt` → `set`

The text commands in this menu include:

`automatic?`

Enables/disables the option to automatically adapt overset meshes during the calculation, to remove orphans, reduce size mismatches between donor and receptor cells, and/or increase the mesh resolution in gaps as needed (in order to prevent the creation of orphan cells). This option is disabled by default.

`maximum-refinement-level`

Sets the maximum level of refinement during overset adaption, in conjunction with the value set using the `mesh/adapt/set/maximum-refinement-level` text command (the larger of the two values is used). This is set to 4 by default.

`mark-size?`

Enables/disables the option to adapt based on donor-receptor cell size differences.

`length-ratio-max`

Sets the length scale ratio threshold used to determine which cells are marked for adaption based on donor-receptor cell size differences. This is set to 3 by default and is only available when `define/overset-interfaces/adapt/set/mark-size?` is enabled.

`mark-orphans?`

Enables/disables the option to adapt for orphan reduction.

`buffer-layers`

Sets the number of cell layers marked in addition to the cells marked for orphan adaption. This is set to 1 by default.

`mark-fixed-orphans?`

Enables/disables the option to also adapt based on cells that are not actual orphans because they were fixed by accepting neighbor donors. This option is only available when `define/overset-interfaces/adapt/set/mark-orphans?` is enabled.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

mark-gaps?

Enables/disables the option to adapt under-resolved gaps in order to prevent the creation of orphan cells. This option is disabled by default.

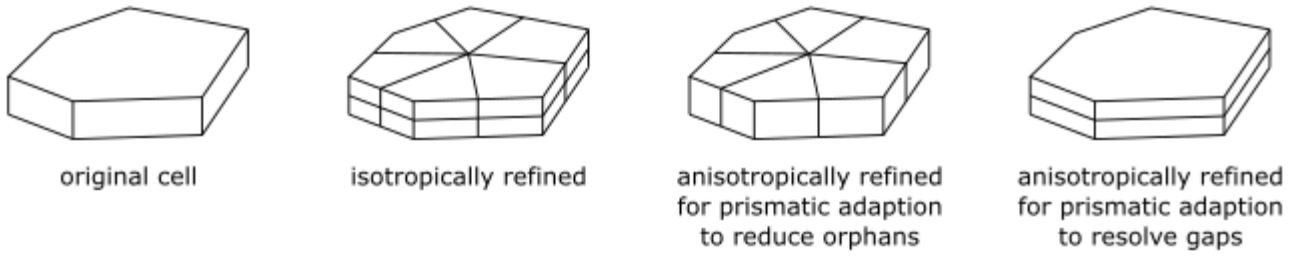
gap-resolution

Sets the target (minimum) gap resolution used when marking cells for gap adaption. This is set to 4 by default and is only available when `define/overset-interfaces/adapt/set/mark-gaps?` is enabled.

prismatic?

Enables/disables the option to use prismatic adaption for the cells that are refined in order to reduce orphans and/or better resolve gaps. Instead of being isotropically refined, these cells will be anisotropically refined (that is, they will not be split on particular edges), in order to reduce the resulting cell count. This adaption option is referred to as "prismatic", because it is only available for 3D prismatic cells that are deemed suitable. For orphan adaption, the goal is to produce cells that have a lower aspect ratio; for gap adaption, the goal is to produce a mesh resolution that is suitable for boundary layers near walls.

Figure 6.72: Prismatic Adaption Examples



mark-coarsening?

Enables/disables the option to coarsen the mesh if mesh refinement is no longer needed. This option is enabled by default.

adaption-sweeps

Sets the number of sweeps of adaption applied during each adaption cycle. This is set to 2 by default.

6.7.6. Overset Meshing Best Practices

Receptor and donor cell sizes should be comparable to ensure that interpolation errors are minimized. You can adapt the mesh to reduce the mismatch between donors and receptors (see Overset Mesh Adaption (p. 1195)).

You must have a minimum of four cells in a gap to create a valid overset interface, but a higher number is recommended to ensure robust coupling between meshes and to prevent the creation of orphan cells (see Figure 6.70: Invalid Overlap Creating Orphans (p. 1195) and Figure 6.69: Valid Overlap (p. 1193)). You can adapt the mesh to refine under-resolved gaps (see Overset Mesh Adaption (p. 1195)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When using the pressure-based solver, the default pressure-velocity coupling scheme for overset meshes is **Coupled**, and this is generally recommended. However, for transient simulations using time step sizes comparable to CFL limits, the greater computational efficiency of a segregated scheme (**SIMPLE**, **SIMPLEC**, or **PISO**) can help in reducing the total simulation time. Note that as you employ larger time step sizes with respect to CFL limits, the tighter pressure-velocity coupling offered by the default **Coupled** scheme makes it the preferred scheme for such cases. For details on these schemes, see Choosing the Pressure-Velocity Coupling Method (p. 3571).

The use of standard initialization with defaults computed from all zones has been found to be useful for turbulent simulations starting from quiescent flow, especially for the segregated pressure-velocity coupling schemes.

It is recommended that you start transient simulations from a converged steady-state solution.

If you are experiencing startup issues with a steady-state case, it is recommended that you ramp-up to the final boundary conditions. For example, you can begin with a lower inlet velocity and a higher viscosity to establish flow, before increasing to the target velocity and the desired final material properties.

When using automatic time step calculation for the pseudo time method (with the global time step method selected), it is recommended that you use the user-specified length scale method.

If you replace a zone that is part of an overset interface, you should either reinitialize the solution or patch the solution on the replaced zone(s) before continuing with the calculation.

It is recommended that you use the double-precision solver for overset mesh simulations.

Closed domain cases are defined as setups that do not have a flow inlet or outlet boundary; this type of setup is not supported with overset meshing if the working fluid is incompressible. If such a setup is unavoidable, creating a small pressure-outlet boundary far away from the region of interest is recommended before attempting to run the case using overset meshes.

For dynamic and sliding mesh cases, note the following:

- The ideal time step size should be chosen such that the relative mesh motion does not exceed the length of the smallest cell at the overset interface for a given time step for first order in time, and half that length for second order in time. The mesh length used for calculating the time step size should be restricted to cells in the overset overlap region. This ensures a more gradual evolution of the overset interface with the motion and is recommended for better accuracy and stability.

- With Volume of Fluid (VOF) simulations using second order in time, the solution strategies for multiphase modeling could be beneficial in improving the stability of your simulations (see VOF Solution Stability Controls (p. 3188)). When using a large CFL value (that is, greater than 1), it is recommended that you run with first order in time to ensure the simulations remain stable.

- In general, the motion of the overset interface may change the status for individual cells from dead to receptor or solve, and vice versa. The exact instances depend on the relative mesh sizes of the moving cell zones participating in the overset interface, the magnitude of the relative mesh velocity, and the time step size. There is currently no mechanism to eliminate this type of cell status change for general cases.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- While the solver is capable of handling the cell status change, it is recommended that you actively monitor these instances by setting the overset mesh verbosity to 1 using the `define/overset-interface/options/verbosity` text command. With such a verbosity, the solver reports the instances of dead to solve cells in the console. Keeping these to a minimum is highly recommended for better accuracy and stability.
- Do not have large variations in mesh resolution in the motion path that could trigger large changes in the overset interface as the motion proceeds. The use of grid priorities can minimize large variations in the overset interface.
- When using an overset mesh to simulate flow through narrow gaps that open or close over time (such as in a valve or a rotary pump), you can use the gap model to block or decelerate the flow when the gaps are closed (as described in Controlling Flow in Narrow Gaps for Valves and Pumps (p. 1211)).

You can specify that the overset interfaces use either the least squares interpolation method (the default) or the inverse distance interpolation method by using the following text command.

`solve` → `set` → `overset` → `interpolation-method`

When the porous zone option is enabled with an overset mesh, it is recommended that you use the default least squares overset interpolation method, especially if you have a porous zone that overlaps with another porous zone. If you need to use the inverse distance interpolation method, you may also need to use pressure interpolation schemes other than second order, as well as enable the use of high-order pressure extrapolation at the overset interface (available through the following text command: `solve/set/overset/high-order-pressure? yes`). This improves the accuracy of the pressure gradients at the overset interface, which is vital for predicting the pressure drop and flow in the porous zone.

6.7.7. Overset Meshing Limitations and Compatibilities

Overset meshing has the following limitations and compatibilities:

6.7.7.1. Limitations

Overset meshing currently has the following limitations:

- Overset interfaces cannot contain **solid** cell zones.
- Non-conformal mesh interfaces inside overset cell zones are only permitted if the mesh interfaces do not spatially overlap with the cells where the overset interfaces lie.
- Component zones cannot have **periodic** boundary conditions.
- Background zones cannot have **overset** boundaries.
- Component mesh boundaries cannot overlap with coupled walls.
- FMG initialization is not available.
- The FAS multigrid scheme is not used.
- Implicit residual smoothing cannot be enabled.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Overset meshing is not supported for incompressible flows in a closed domain.
- The use of node weights for node-based gradients in postprocessing is not available for cases with overset meshes.
- Overset meshing is not compatible with the **Coupled Level Set + VOF** hybrid model.
- The turbulence models that are supported with overset meshing (listed in the section that follows) cannot be used in combination with Scale-Resolving Simulation (SRS) models / options.
- When using an overset mesh with the DPM model:
  - The **High-Res Tracking** option must be enabled
  - Wall film particles cannot move between different overset meshes

6.7.7.2. Compatibilities

Overset meshing is compatible with the transient and steady-state solvers. Both laminar and turbulent flow regimes with heat transfer are allowed as well as single phase flows, and Volume of Fluid (VOF) and mixture multiphase flows. These applications are valid with overset for the listed solver options and configurations. Unless otherwise specified, consider all other solver features and models to be unsupported.

Supported Options and Models:

- Pressure-based solver using:
  - 2D (planar and axisymmetric) and 3D flows in the absolute velocity formulation
  - Compressible flows
  - Cell-based gradient methods: **Green-Gauss Cell Based** and **Least Squares Cell Based**
  - All pressure interpolation schemes
  - First-order and second-order spatial schemes
  - **SIMPLE**, **SIMPLEC**, **PISO**, **Fractional Step**, and **Coupled** schemes for pressure-velocity coupling
  - All mass flux types (**Rhie-Chow: distance based** or **Rhie-Chow: momentum based**)
  - A pseudo time method
  - First-order, second-order, and (if available) bounded second-order transient formulations
  - The Non-Iterative Time Advancement (NITA) option
  - The hybrid NITA option (for cases that involve the Volume of Fluid model)
- Density-based solver using:
  - 2D (planar and axisymmetric) and 3D flows in the absolute velocity formulation
  - Compressible flows

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

  - Cell-based gradient methods: **Green-Gauss Cell Based** and **Least Squares Cell Based**
  - All convective flux types (**Roe-FDS**, **AUSM**, and **Low Diffusion Roe-FDS**)
  - First-order and second-order spatial schemes
  - A pseudo time method
  - First-order, second-order, and (if available) bounded second-order transient formulations
- k-ε turbulence models: Standard, RNG, and Realizable
- k-ω turbulence models: Standard, BSL, and SST
- Spalart-Allmaras turbulence model
- Laminar-turbulent transition models: Transition SST, Intermittency Transition, and Transition k-kl-ω
- Discrete Ordinates (DO) radiation model
- Species transport model:
  - single-phase flow only
  - reactions must be disabled
- VOF models:
  - Open channel flow and surface gravity waves
  - Cavitation and evaporation/condensation mass transfer
- Mixture multiphase model:
  - Non-granular flows
  - Cavitation and evaporation/condensation mass transfer
- Cavitation and evaporation/condensation mass transfer in VOF/Mixture multiphase applications
- Non-granular flows in multiphase applications
- Dynamic and sliding meshes with the first-order transient formulation
- Gap model
- User-defined scalars
- User-defined functions (for information about overset-specific macros that can be useful when writing user-defined functions, see Overset Mesh Looping Macros in the Fluent Customization Manual)
- All AMG options except for the **Laplace Coarsening** option (for the scalar or coupled parameters)
- All boundary conditions are supported except for:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

  - the following non-interior face zone boundary conditions: exhaust fan, inlet vent, intake fan, outflow, and outlet vent
  - the following interior face zone boundary conditions: fan, porous-jump, and radiator
- Cell zone conditions
  - Source terms may only be defined on cell zones not participating in an overset interface
  - Fixed values may only be defined on cell zones not participating in an overset interface
  - Multiple Reference Frame (MRF) model
  - The porous zone option is supported with the superficial velocity formulation
- Hybrid and standard initialization
- An overset meshing solution may be obtained on any mesh type, including adapted meshes

6.7.8. Setting up an Overset Interface

Once you have read all of the related meshes into Fluent, use the following steps to setup an overset interface.

1. Change the boundary zones of component meshes to **overset** (boundary type), where needed.

   Important:

   You must correctly specify the **overset** boundaries for all zones in an overset interface before creating the overset interface. (Once overset interfaces are created you cannot change any boundaries from **overset** to another type or from another type to **overset**.)

   Setup → **Boundary Conditions** **<boundary>** → **Type** → **overset**

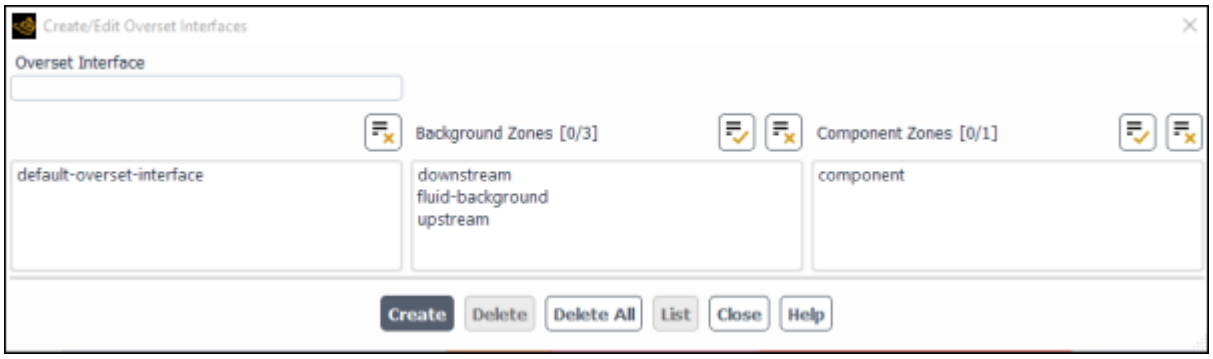
   The Overset Dialog Box (p. 4987) will open, which you can use to revise the **Zone Name**.

2. Create an overset interface between the cell zones that must be coupled. A case can have multiple interfaces. Each interface must have at least one background and one component mesh.

   Domain → **Interfaces** → **Overset**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.73: Create/Edit Overset Interfaces Dialog Box



a. Enter a name under **Overset Interface**.

b. Select the zones of the interface in the **Background Zones** and **Component Zones** selection lists. Ansys Fluent allows you to create interfaces that contain only component zones; in such cases, you do not select a background zone, but instead select two or more component zones.

c. Click **Create**.

3. (optional) If your overset case doesn't have overlapping boundaries, and you don't need Fluent to analyze the case for boundary overlaps, you can improve the overset performance by disabling overlap boundaries using the following text command:

   `define → overset-interfaces → options → overlap-boundaries?`

4. (optional) Use the text user interface for additional control over the hole cutting step of the interface initialization.

   - If certain boundary zones should not cut particular cell zones, use the `define/overset-interfaces/cut-control/add` text command to set up cut control.

   - If component meshes have no boundaries that will cut a cell zone, you can use the `define/overset-interfaces/cut-control/cut-seeds/cut-seeds-for-all-component-zones?` text command to ensure that all component zones get cut seeds (see Hole Cutting Control (p. 1190)).

5. (optional) Use the text user interface for additional control over the overlap minimization of the overset interface. It can be helpful to revise the default settings if your overlapping meshes have uniform and nearly identical resolutions or if local mesh distributions are irregular, as this may improve the computational efficiency and/or the solution quality. See Overlap Minimization (p. 1191) for details.

   - To specify whether the cell donor priorities used during minimization are based on the cell size or distance to the nearest boundary, use the following text command:

     `define → overset-interfaces → options → donor-priority-method`

   - To revise the grid priorities during minimization, use the following text command. The grid priority for each zone is an integer, and only the relative values between the zones matter.

     `define → overset-interfaces → grid-priorities`

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- To disable overlap minimization entirely, use the following text command. This command is only available globally and applies to all overset interfaces in the domain.

  `define` → `overset-interfaces` → `options` → `minimize-overlap?`

Note that these steps only define an overset interface. Hole cutting occurs during solution initialization.

If a case contains **overset** face zones, but no defined overset interfaces, then Fluent creates a default interface with the name `default-overset-interface` upon initialization. This default overset interface contains all cell zones in the domain. If you know that some cell zones do not need to be included in an overset interface, then you can increase the solution performance by manually creating the interface and only including the relevant background and component meshes.

6.7.9. Postprocessing Overset Meshes

Fluent has several overset-specific postprocessing tools to help you analyze/understand the domain connectivity. These tools are only available after the flow field is initialized and the domain connectivity is established.

6.7.9.1. Overset Mesh Display

6.7.9.2. Overset Field Functions

6.7.9.3. Overset Cell Marks

6.7.9.4. Overset Interface Listing

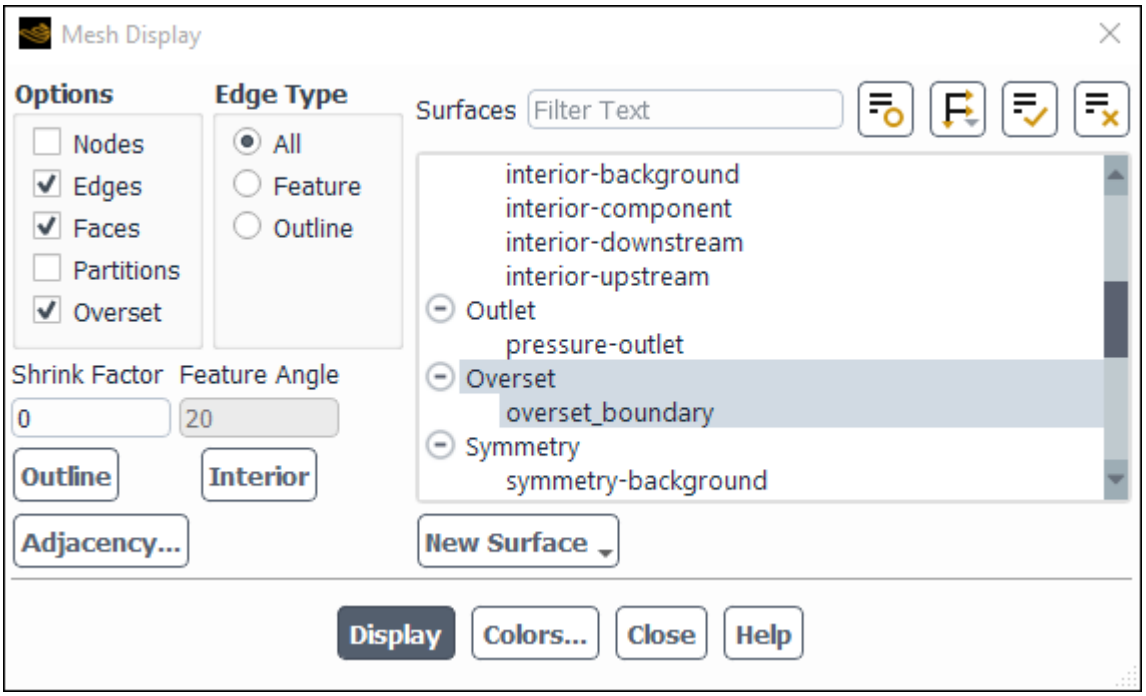
6.7.9.5. Overset Postprocessing Limitations

6.7.9.1. Overset Mesh Display

You can either visualize the complete mesh or just the active cells. If the **Overset** option is enabled in the **Mesh Display** dialog box, by default only solve cells are shown. Disabling the **Overset** option displays the complete surfaces.

Domain → **Mesh** → **Display**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



You have the option to have receptor cells displayed along with the solve cells when **Overset** is selected. You can enable this option via the TUI command `define/overset-interfaces/options/render-receptor-cells?`.

Note:

- When displaying contours of postprocessing quantities, dead cell values are never shown, regardless of whether or not **Overset** is enabled in the **Mesh Display** dialog box.
- You may notice a z-fighting effect when displaying overset meshes, particularly when coloring the mesh by ID. This occurs due to the nature of overset meshes, where two meshes are coincident and the rendering tool is conflicted in determining which color to display.

6.7.9.2. Overset Field Functions

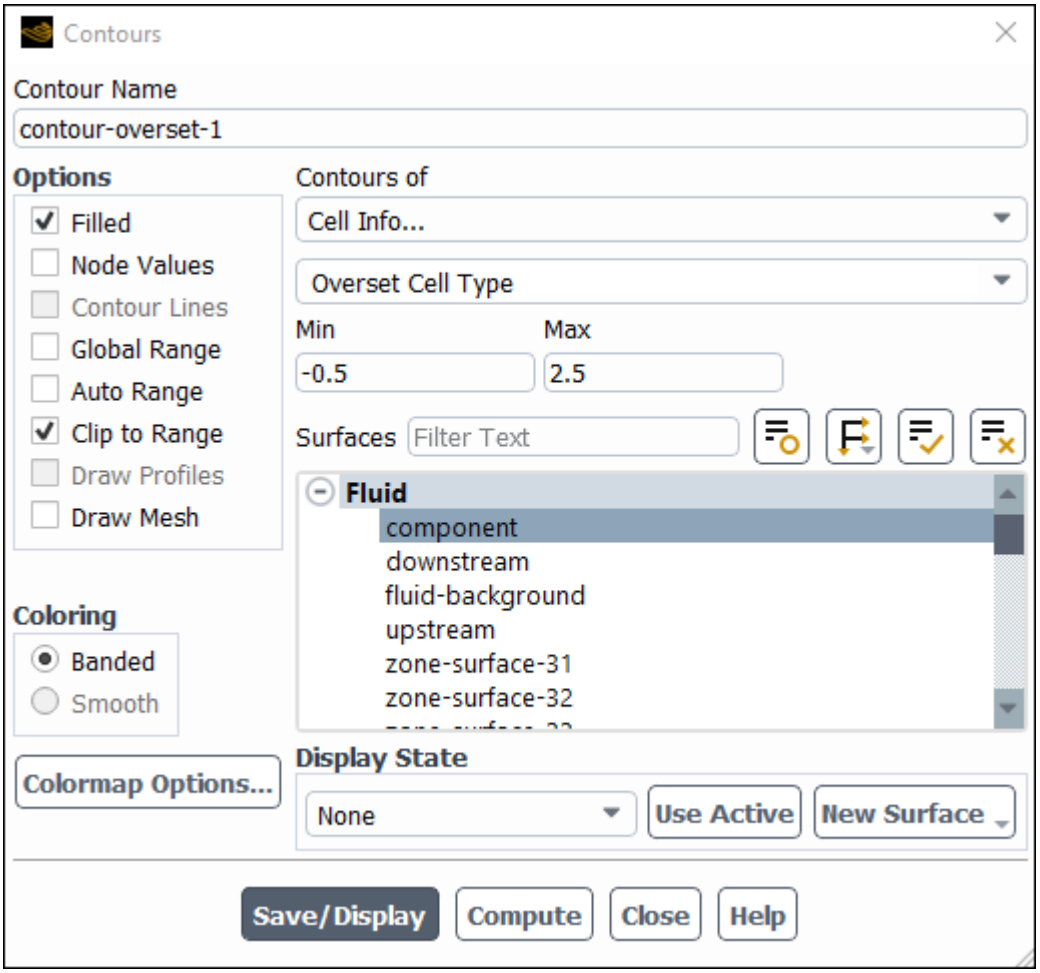
There is an **Overset Cell Type** function available in the **Cell Info...** category in the Contours Dialog Box (p. 5357). The integer function value depends on the overset cell type:

Cell Type	Integer Function Value
donor	2
solve	1
receptor	0
orphan	–1
dead	–2

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This field function is also available in the **Contours** dialog box.

Results → Graphics → Contours → New...



1. Select **Cell Info...** and **Overset Cell Type** from the **Contours of** drop-down lists.
2. Choose the surfaces containing the overset cells you want to visualize and click **Display**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.74: Contours of Overset Cell Type: Background Mesh

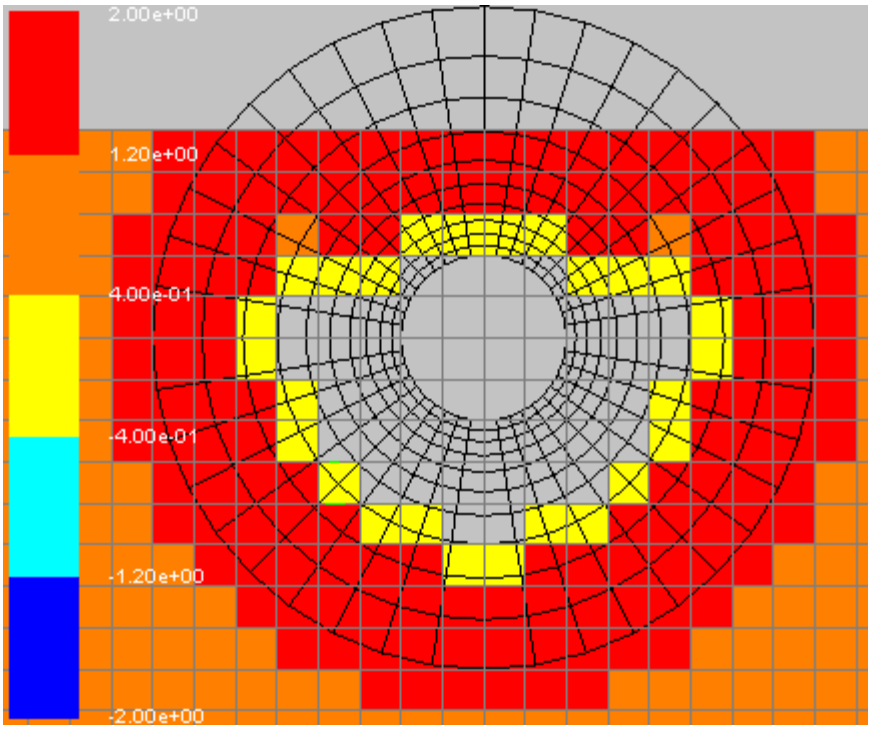


Figure 6.75: Contours of Overset Cell Type: Component Mesh

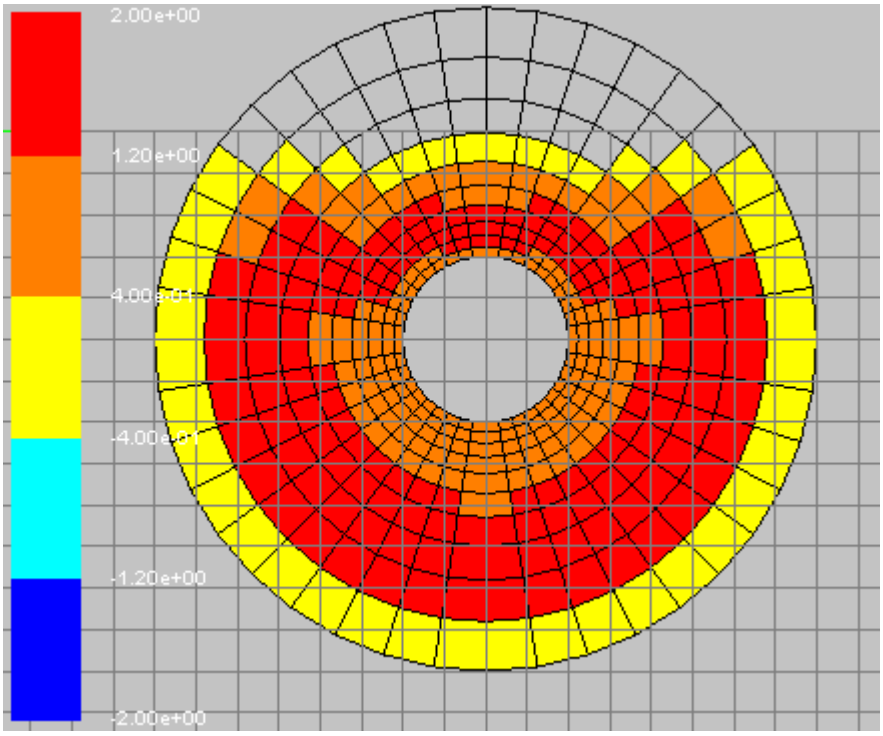

Figure 6.74: Contours of Overset Cell Type: Background Mesh (p. 1209) and Figure 6.75: Contours of Overset Cell Type: Component Mesh (p. 1209) display a background mesh and component mesh

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

(sequentially) of **Overset Cell Type** for the cylinder problem shown in Figure 6.55: Overset Component and Background Mesh (p. 1184).

Note:

If you want to display orphan cells, then you must enable the TUI command `define/overset-interfaces/options/render-receptor-cells?`.

If the expert options are enabled under `define/overset-interfaces/options/expert?`, then you can also choose to display **Overset Donor Count** and **Overset Receptor Count** under **Cell Info…**. The **Overset Donor Count** is filled for each receptor and shows the number of donors. Similarly, the **Overset Receptor Count** is filled for donor cells and shows the number of receptors that are referencing the donors.

Note that the donor counts reported are the maximum number of donors available for the data interpolation. The actual number of donors used by the solver may be less.

6.7.9.3. Overset Cell Marks

It can be difficult to interpret contours of overset cells in 3D. Often, it is more illustrative to mark a certain type of overset cells and display these marked cells.

Using the text command `define/overset-interfaces/mark-cells` you can mark cells of specified overset cell type (solve, receptor, donor, orphan, or dead), either globally or on a single cell zone. This command automatically fills registers that can be displayed using the `define/overset-interfaces/display-cells` text command.

6.7.9.4. Overset Interface Listing

Use the text command `define/overset-interfaces/list` to print overset interface related information to the console. If the overset verbosity, `define/overset-interfaces/options/verbosity`, is set to `1`, then counts of each overset cell type are printed per cell zone as well.

6.7.9.5. Overset Postprocessing Limitations

Volume integrals are taken over all solve cells in the domain. This results in double counting where solve cells overlap, leading to errors in volume integrals on overset meshes.

Similarly, surface integrals, including force and moment reports, will include errors when taken on surfaces created for postprocessing (such as plane surfaces or rake surfaces) in regions where solve cells or boundary zones overlap. If surface integrals are taken on boundary zones rather than created surfaces and/or in a region without overlap, then the surface integrals are exact.

Important:

Errors in integral evaluations scale with the size of the overlap.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.7.10. Writing and Reading Overset Files

When writing overset case files, it is recommended that you use the default Common Fluids Format (CFF), as in this format the overset domain connectivity is saved in the `.cas.h5` file. This makes it unnecessary to reestablish the domain connectivity when reading an overset case into a new session, as is the case with legacy case files (`.cas`). It also guarantees an identical connectivity when a case is read on a different number of compute nodes.

When you write an overset case file in CFF and the case has not yet been initialized, Ansys Fluent will by default establish the domain connectivity prior to writing the file. This can be disabled using the `define/overset-interfaces/options/update-before-case-write?` text command, which is available after you enable the expert tools using the `define/overset-interfaces/options/expert?` command.

6.8. Controlling Flow in Narrow Gaps for Valves and Pumps

When using dynamic meshes, overset meshes, and/or sliding meshes to simulate flow through narrow gaps that open or close over time (such as in a valve or a rotary pump), you can use the gap model to block or decelerate the flow when the gaps are closed. The following sections provide details:

6.8.1. The Gap Model Approach

6.8.2. Limitations of the Gap Model

6.8.3. Recommendations for the Setup of a Simulation with Gaps

6.8.4. Using the Gap Model

6.8.1. The Gap Model Approach

For transient flows with moving face zones, narrow gaps may open or close during every time step. You can use the gap model to simulate the blockage of flow when a gap is closed. A gap region is made up of a pair of face zones, so that when one moves within a specified proximity threshold distance of the other, the fluid cells within the threshold of the zones are marked, and then the flow is blocked at the boundary faces of the marked region so that the marked cells no longer participate in the solution (for what is called a flow-blocking type region) or else decelerated in the marked region (for what is called a flow-modeling type region). The gap model has the following advantages:

- With the flow-blocking type, you can ensure that there is no flow leakage. This is a realistic flow condition for valves in the closed position.
- When the flow-blocking type does not produce a stable solution or is otherwise not preferred, you can use the flow-modeling type to decelerate the flow inside the gap regions and minimize leakage.
- It can reduce computational cost in narrow gaps by reducing the need for a high cell count to resolve high solution gradients in the flow between walls in close proximity (for example, a valve opening and closing).
- The flow-blocking type can avoid the difficulties of meshing and/or remeshing in narrow passages, especially with moving deforming meshes.
- You can define multiple gap regions, each with a unique proximity threshold.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.8.2. Limitations of the Gap Model

The following are not supported with the gap model:

- density-based solver
- axisymmetric swirl
- Eulerian multiphase model
- ablation model
- Eulerian wall film model
- Lagrangian wall film model
- solidification/melting model
- electric potential model
- Lithium-ion battery model
- acoustics models
- structural model
- discrete phase model (DPM)
- radiation models
- species models (with the exception of species transport for mixing but not reacting)
- pollutant formation models
- reactor network model
- decoupled detailed chemistry pollutant model
- multiphase flow with species transport
- the following turbulence models / options: Reynolds stress models (RSM), Scale-Adaptive Simulation (SAS) model, Detached eddy simulation (DES) model, Large Eddy Simulation (LES) model, Scale-Resolving Simulation Options (SAS, DES, or SBES/SDES)
- **Green-Gauss Node Based** gradient method (for flow-blocking type only)
- **QUICK** or **MUSCL** discretization schemes (for flow-blocking type only)
- Non-Iterative Time Advancement (NITA) scheme
- coupled walls are not allowed to be selected for a gap region
- the gap model cannot be used in a case that also has the **Flow Control** option enabled in the **Contact Detection** tab of the Options Dialog Box (p. 5067)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- the porous zone option cannot be enabled in cell zones where gaps are located

6.8.3. Recommendations for the Setup of a Simulation with Gaps

Note the following recommendations when setting up a case that uses the gap model:

Boundary Conditions

If flow blocking is used to control the flow in the gap regions of a single passage domain and the flow stream is detached from the upstream region to the downstream region, it is recommended that you do not use boundary conditions of the following types: **velocity-inlet**, **outflow**, and/or **mass-flow-inlet**; instead, the **pressure-inlet** and **pressure-outlet** types are preferred.

Important:

You must avoid boundary conditions of type **fan**, **porous-jump**, and/or **periodic** in the vicinity of either type of gap region.

Materials

In domains with blocking gap regions, incompressible liquids and constricting and expanding volumes can create unphysical pressure spikes. Therefore, it is recommended that you select the compressible-liquid option for liquids, or use compressible gas options such as the ideal gas law for gases. In case of incompressible liquids, you can also use a user-defined function (UDF) and add compressibility to provide a realistic setup.

Stability and Convergence

The time step size requires special attention when the gap model is used. A larger time step size can be used when there is no blocked gap region in the domain compared with the condition where one or multiple blocking regions exist in the domain. It is recommended that you use adaptive time stepping to dynamically adjust the time step size depending the flow condition, and set the Courant (CFL) number to 1.

Whenever poor solution convergence behavior is observed, some or all of the following recommendations may help: ensure that the initialization settings are appropriate (especially the turbulence settings); start the simulations with lower-order numerics and then move to second-order discretization; reduce the time step size; and/or reduce the momentum under-relaxation factor to 0.2. You may also want to enable the **High Order Term Relaxation** option in case the solution field variation is very considerable per each time step.

If these suggestions do not help, you can gradually increase the **Stabilization Level** from **None** in the **Advanced Options** dialog box (as described in the section that follows) and increase the maximum iterations per time step. You can also refine the mesh in the vicinity of the gap regions.

6.8.4. Using the Gap Model

To use the gap model, perform the following steps:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Set up a dynamic mesh, overset mesh, and/or sliding mesh with a narrow gap that opens or closes over time (such as in a valve or a rotary pump). You must ensure that the setup respects the limitations and recommendations noted in the preceding sections.

2. Open the **Gap Model** dialog box by clicking the **Gap Model...** button in the **Domain** ribbon tab (**Mesh Models** group):

   Domain → **Mesh Models** → **Gap Model...**

   Figure 6.76: The Gap Model Dialog Box

   a. Create one or more gap regions using the input controls in the **Gap Definition** group box. For each one:

      i. Provide a **Gap Name**. The name cannot consist solely of numbers.

      ii. Select two or more face zones (of type wall or symmetry) that could come in close proximity to each other from the **Face Zones** list; note that a given face zone may be used in multiple gap regions, but two or more face zones used in one gap region may not all be used in one other gap region. It is recommended that you use the minimum number of face zones as possible per gap region, as additional unnecessary face zones will adversely affect the calculation speed.

      iii. Specify a **Proximity Threshold**, that is, the maximum distance between the face zones when flow blockage / deceleration occurs.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

iv. Select one of the following from the **Gap Type** drop-down list:

- **Flow-Blocking**

  This type completely blocks the flow in the gap region, as a numerical zero-mass-flux boundary condition is applied at the boundary faces of the marked region so that the marked cells no longer participate in the solution. This can be appropriate for a valve that completely closes. It is recommended that you use this for meshes that only move translationally. Meshes that undergo rotational motion (such as gears or pumps) may experience divergence; in such cases, it may be possible to proceed using a larger proximity threshold so that the region of cells marked for blockage is larger (and you thus avoid creating "islands" of unmarked cells surrounded by marked cells).

- **Flow-Modeling**

  This type decelerates the flow in the cells of the marked region by manipulating the viscosity or source terms. Since it allows some leakage (though this can be negligible, based on your setup), it can be more robust if appropriately set up. It is recommended for meshes that undergo rotational motion, such as gears or pumps.

  If you plan on controlling the flow based on the viscosity (the default method), you should specify an appropriate **Gap Reynolds Number** in order to obtain the desired level of sealing. A lower **Gap Reynolds Number** results in better sealing. You can determine a suitable value through trial and error during the simulation, or estimate it using the expected properties in the gap region according to the following equation:

$$\mathrm{Re}_{\mathrm{gap}}=\frac{\rho_{\mathrm{avg}}u_{\mathrm{avg}}L}{\mu_{\mathrm{avg}}} \tag{6.4}$$

  where

  $\mathrm{Re}_{\mathrm{gap}}$ = gap Reynolds number

  ρ_{avg} = averaged density

  u_{avg} = averaged velocity

  L = proximity threshold

  μ_{avg} = averaged laminar viscosity

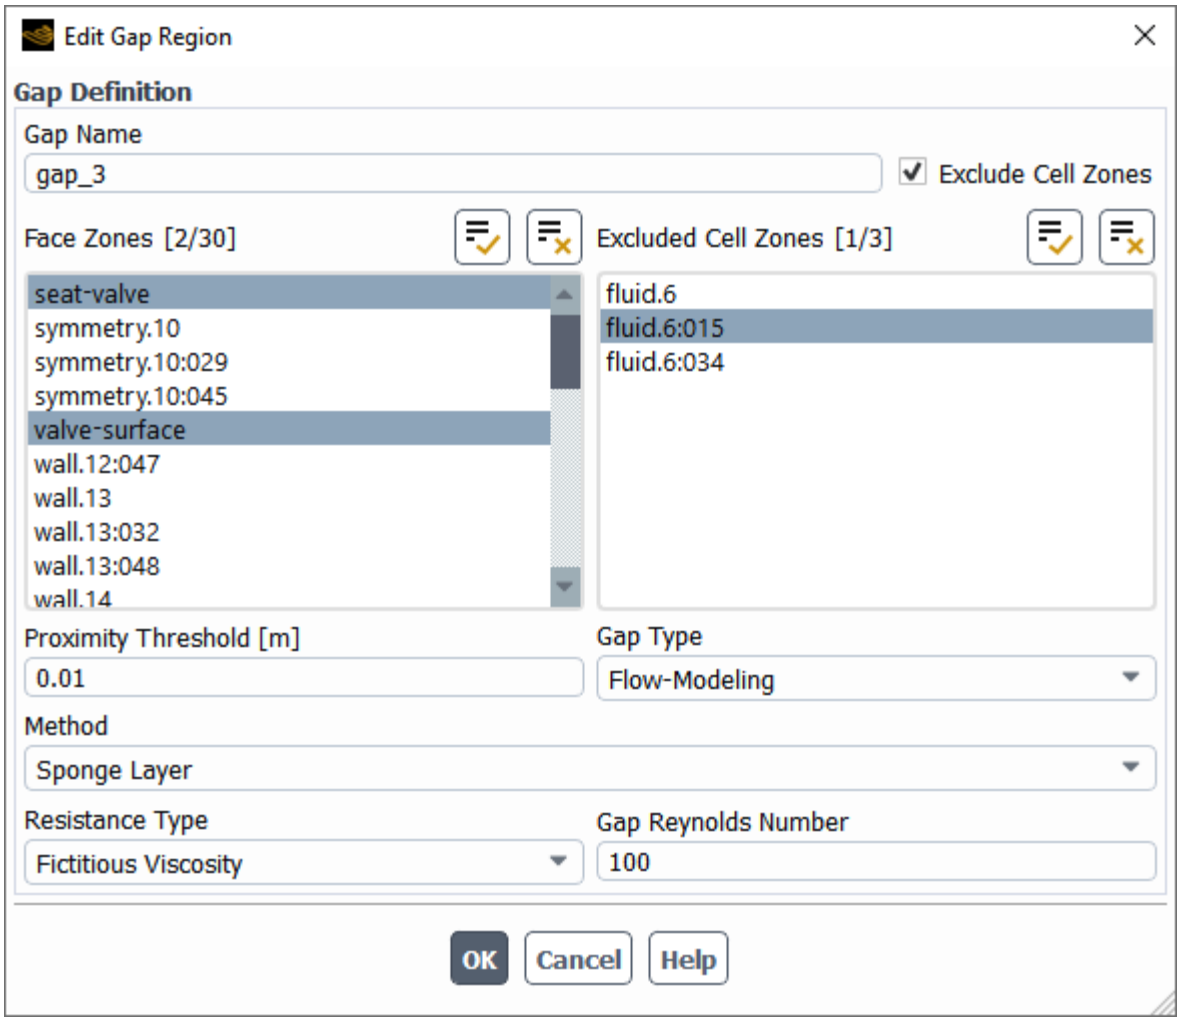
v. Click **Create**.

b. After you have created gap regions, you can revise the setup using the input controls in the **Gap Management** group box.

i. Revise a gap region by making a single selection from the **Gap Regions** list, clicking **Edit...**, and then completing the setup in the **Edit Gap Region** dialog box that opens.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.77: The Edit Gap Region Dialog Box

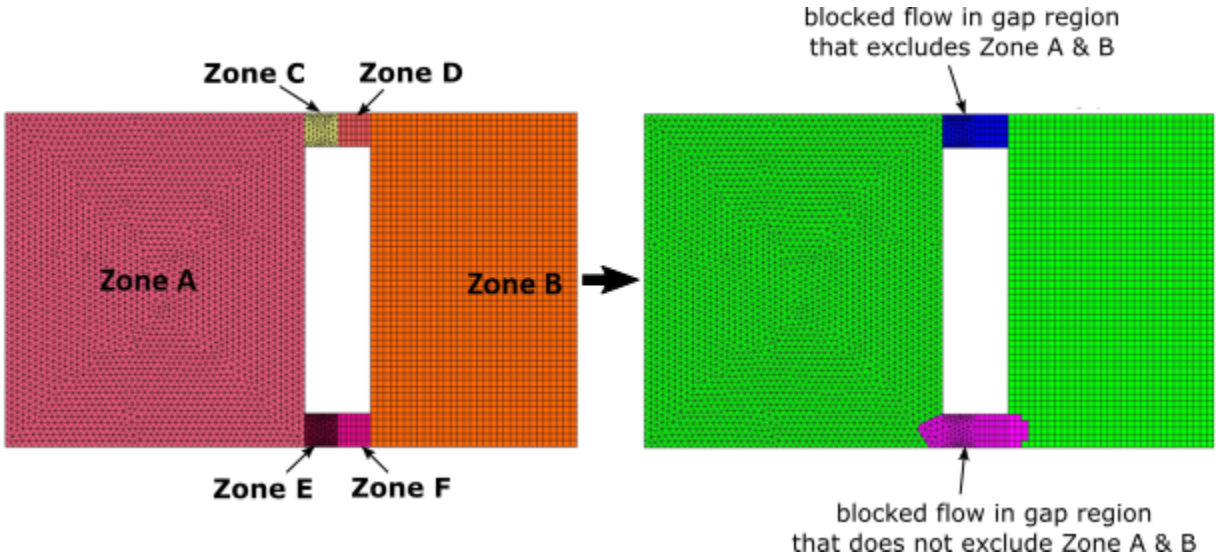


In addition to the input controls you used when initially creating the gap region, the following settings can be defined:

- You can enable the **Exclude Cell Zones** option and then make selections from the **Excluded Cell Zones** list, in order to specify that cells in particular cell zones are not marked for flow blockage / deceleration as part of the gap region. In this way you can have greater control over the shape of the gap region, as shown in the figure that follows.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.78: Controlling Gap Shape by Excluding Zones



Note:

The **Exclude Cell Zones** option is automatically disabled for simulations that use overset meshes, as this combination is not supported.

- If you selected **Flow-Modeling** for the **Gap Type**, you can select a **Method**:
  - **Sponge Layer**

    This specifies that the viscosity inside the gap regions is scaled based on the specified **Gap Reynolds Number**. As the viscosity increases, the velocity in the gap region decreases. As part of this method, you can specify the **Resistance Type**, which affects the nature of the viscosity scaling: by default, the **Fictitious Viscosity** approach is used, as it is more robust and has less impact on thermal simulations. It scales the laminar viscosity inside the gap region during discretization of the viscous forces for the momentum equation; thus, its impact is explicitly seen in the velocity and pressure computation, and it has an implicit effect on the other solution fields through the changes in the velocity and pressure field. You can instead select the **Real Viscosity** approach, which changes the actual laminar viscosity inside the gap region based on your specified **Gap Reynolds Number**; therefore, the effect of modeling will be seen not only in flow equation but also in other equations. The flow inside the gap region modeled by this approach is indeed using a modified viscosity value over the course of the entire simulation.

  - **User-Defined Source**

    This allows you to use a user-defined function (UDF) to specify the source terms for the momentum and energy equations in the gap region using the `DEFINE_GAP_MODEL_SOURCE` macro (for details, see `DEFINE_GAP_MODEL_SOURCE` in the *Fluent Customization Manual*). After you have compiled the UDF, you must then select it in the **Gap Source Terms** field. Note that interpreted UDFs are not supported.

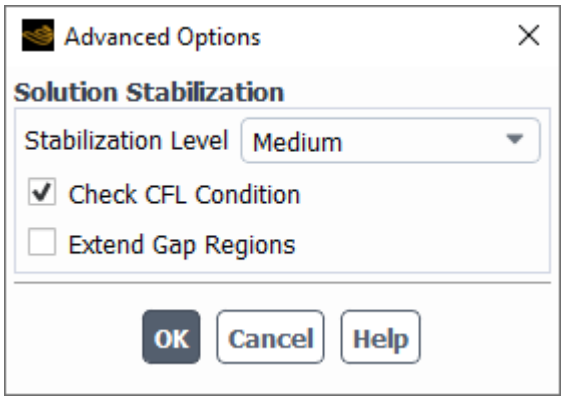
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ii. To delete gap regions, select one or more in the **Gap Regions** list and click the **Delete** button.

iii. To print a list in the console of the properties of gap regions, select one or more in the **Gap Regions** list and click the **List** button. Note that the number of cells marked for blockage / deceleration will not be updated until after you have generated data by initializing or calculating.

iv. A gap region can introduce large gradients in the flow in the vicinity of the gap region boundary. You have the option of applying solution stabilization to improve the stability of the simulation by clicking the **Advanced Options...** button and selecting a **Stabilization Level** in the dialog box that opens. For each level, the solver adjusts the numerical settings, discretization schemes, under-relaxations, AMG settings, and so on, and controls the flow behavior in the vicinity of the gap regions; note that these changes are applied globally to all gap regions, and a level other than **None** will override the local stabilization applied by default to flow-modeling regions that use the **Sponge Layer** method. You should use the lowest level as possible, as the cost of computation increases with higher levels. Information about any changes made as part of this stabilization is printed in the console when you click **OK**.

Figure 6.79: The Advanced Options Dialog Box



You can enable the **Check CFL Condition** option if you want Fluent to determine a desirable acoustic Courant (CFL) number based on your selected **Stabilization Level**, and then provide a warning message in the console if this CFL number would require you to specify a smaller time step for the calculation in order to improve the solver stability.

You can also enable the **Extend Gap Regions** if the shape of the marked cells is negatively affecting solution stability or convergence behavior. The gap regions will then be enlarged during marking by including additional cells in the vicinity of the gap interfaces.

c. When all of the gap regions are properly defined, click the **OK** button to close the **Gap Model** dialog box.

3. When you have a **Flow-Modeling** type gap region that uses the **Sponge Layer** method, by default a local stabilization is enabled to mitigate bad convergence behavior (though it can be disabled for individual gap regions using the `define/gap-model/edit` text command, or overridden generally through stabilization level set in the **Advanced Options** dialog box). You have the ability to revise the settings for all of the gap regions that use this local stabilization through the following text command:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

`define` → `gap-model` → `advanced-options` → `sponge-layer`

- You can set the viscosity variation factor, which determines how much the viscosity linearly varies within the gap region as you approach the center. The default value of `0` produces maximum variability, which is appropriate when the gap size is larger and/or the viscosity within the gap region is very high compared to the flow domain. You can enter values closer to `1` (so that the viscosity is more fixed / constant throughout) when the gap is smaller and/or the viscosity is lower. Minimizing the variability restricts the flow better, but can lead to solution instability.
- You can set minimum limit for the velocity in the sponge layers. Viscosity scaling is disabled if the average velocity inside the gap region is less than this minimum.
- You can set the maximum limit for the viscosity change ratio in the sponge layers. The local stabilization method measures the variation of maximum viscosity to minimum viscosity inside the gap region, and constrains this ratio to be bounded between 0 and the value you enter. This can help avoid numerical instability when the variation of the viscosity inside the gap region is quite substantial compared to the flow viscosity.

4. During the solution, information about the gap model is printed in the console. You can set the level of detail that is provided by using the following text command:

   `define` → `gap-model` → `advanced-options` → `verbosity`

5. Though it is not typically necessary, you can enable the following text command to make additional expert-level text commands available.

   `define` → `gap-model` → `advanced-options` → `expert?`

   The expert-level text commands include the following:

   `define/gap-model/advanced-options/enhanced-data-interpolation?`

   This can enable the use of enhanced data interpolation for updating information in gap regions. It may produce more accurate results, but with a higher computational cost.

   `define/gap-model/advanced-options/fill-data-in-gap-regions?`

   This can enable the interpolation of solution data throughout the gap regions.

   `define/gap-model/advanced-options/precise-gap-marking?`

   This can enable the use of a more accurate search algorithm for marking cells in gap regions. Note that it can be costly, particularly for 3D cases or those with a large number of cells inside the gap regions.

   `define/gap-model/advanced-options/reduce-gap-regions?`

   This can enable a more restrictive algorithm for marking cells in gap regions.

   `define/gap-model/advanced-options/render-flow-modeling-gaps?`

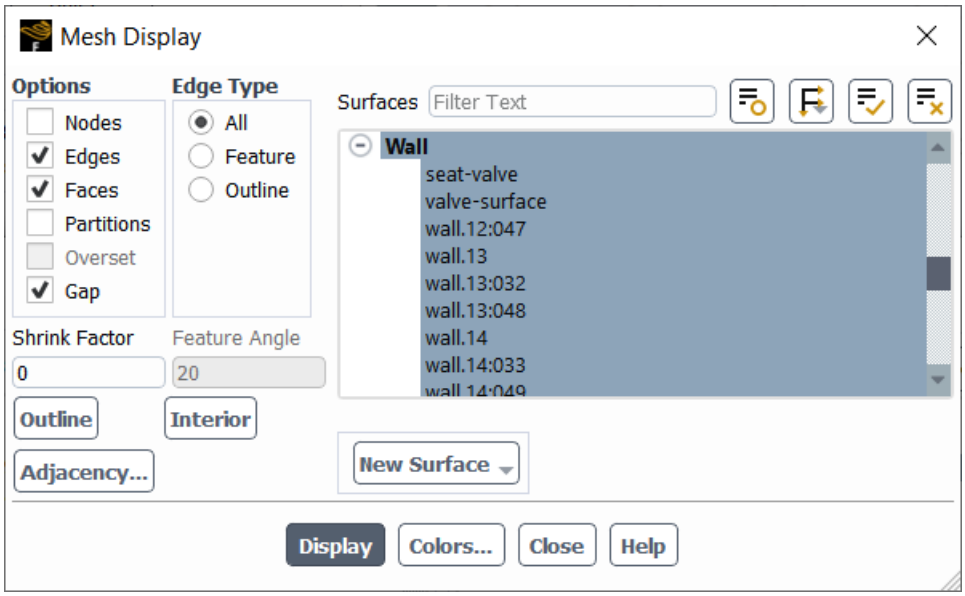
   This can disable the rendering of the solution in the cells of flow-modeling gap regions during postprocessing.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. You can use the **Mesh Display** dialog box to view the mesh. By default, the complete mesh is displayed. If you enable the **Gap** option, only the cells in which flow is allowed are displayed (that is, those that are not marked for blockage in the gap region).

   Domain → Mesh → Display

Figure 6.80: The Mesh Display Dialog Box for a Gap Model Simulation



Note:

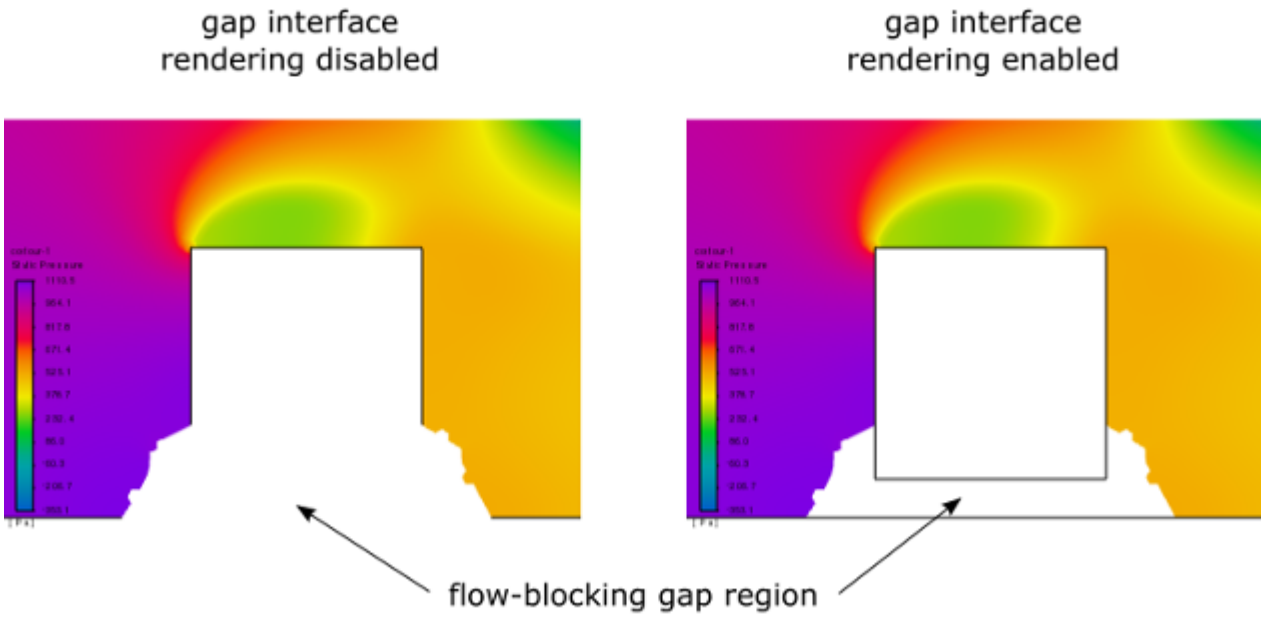
When displaying contours of postprocessing quantities, cells marked for blockage in a gap region are not shown (except for the **Gap ID** or **Gap Type** field variables), regardless of whether or not the **Gap** option is enabled in the **Mesh Display** dialog box.

When displaying the mesh with contours, you can use the following text command to allow the rendering of the mesh surfaces inside the gap regions. Note that the solution is still not rendered inside the flow-blocking gap regions.

`define → gap-model → advanced-options → render-gap-interface?`

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.81: Contours and Mesh with a Flow-Blocking Gap



7. When postprocessing a gap model simulation, note that the **Node Values** option is not supported. The following field variables are available (under the **Cell Info...** category), and may visualize the gap regions:

   - **Gap ID**

     This is the gap region ID, as identified using the **List** button in the Gap Model Dialog Box (p. 5428). All cells that are not marked for a gap region have a value of 0.

   - **Gap Type**

     This is the type of gap region. Cells that are marked as part of a flow-blocking gap region have a value of 1, cells that are marked as part of a flow-modeling gap region have a value of 2, and cells that are not marked for a gap region have a value of 0.

   - **Flow-Blocking Gap Interface**

     This identifies the interfaces of flow-blocking gap regions. All cells that have at least one face that applies the zero-mass-flux boundary for a gap region have a value of 1, whereas all other cells have a value of 0.

Note:

- For steady-state simulations, if you have initialized the solution and then revise a gap region definition or delete a gap region such that there is a change in the cells that are marked for blockage / deceleration, then you must initialize again before proceeding.
- It is recommended that you do not have two or more gap regions overlap (that is, mark the same cells), especially if they are not of the same **Gap Type**. If you enable the verbosity text command (`define/gap-model/advanced-options/verbosity`

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1), you will receive a warning message in the console when gaps overlap. For flow-blocking gaps, you can replace the multiple overlapping gap regions with a single gap region that includes all of the related face zones and has a proximity threshold that is suitable for all.

6.9. Checking the Mesh

The mesh checking capability in Ansys Fluent examines various aspects of the mesh, including the mesh topology, periodic boundaries, simplex counters, and (for axisymmetric cases) node position with respect to the x axis, and provides a mesh check report with details about domain extents, statistics related to cell volume and face area, and information about any problems associated with the mesh. You can check the mesh by clicking the **Check** button in the **General** task page.

Setup → **General** → **Check**

Important:

It is generally a good idea to check your mesh right after reading it into Fluent, in order to detect any mesh trouble before you get started with the problem setup.

The mesh check examines the topological information, beginning with the number of faces and nodes per cell. A triangular cell (2D) should have 3 faces and 3 nodes, a tetrahedral cell (3D) should have 4 faces and 4 nodes, a quadrilateral cell (2D) should have 4 faces and 4 nodes, and a hexahedral cell (3D) should have 6 faces and 8 nodes. Polyhedral cells (3D) will have an arbitrary number of faces and nodes.

Next, the face handedness and face node order for each zone is checked. The zones should contain all right-handed faces, and all faces should have the correct node order.

The last topological verification is checking the element-type consistency. If a mesh does not contain mixed elements (quadrilaterals and triangles or hexahedra and tetrahedra), Ansys Fluent will determine that it does not need to keep track of the element types. By doing so, it can eliminate some unnecessary work.

For axisymmetric cases, the number of nodes below the x axis is listed. Nodes below the x axis are forbidden for axisymmetric cases, since the axisymmetric cell volumes are created by rotating the 2D cell volume about the x axis; therefore nodes below the x axis would create negative volumes.

For solution domains with rotationally periodic boundaries, the minimum, maximum, average, and prescribed periodic angles are computed. A common mistake is to specify the angle incorrectly. For domains with translationally periodic boundaries, the boundary information is checked to ensure that the boundaries are truly periodic.

Finally, the simplex counters are verified. The actual numbers of nodes, faces, and cells that Fluent has constructed are compared to the values specified in the corresponding header declarations in the mesh file. Any discrepancies are reported.

6.9.1. Mesh Check Report

6.9.2. Repairing Meshes

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.9.1. Mesh Check Report

When you click the **Check** button in the **General** task page, a mesh check report will be displayed in the console. The following is a sample of a successful output :

```
 Mesh Check

 Domain Extents:
   x-coordinate: min (m) = -4.000000e-002, max (m) = 2.550000e-001
   y-coordinate: min (m) = 0.000000e+000, max (m) = 2.500000e-002
 Volume statistics:
   minimum volume (m3): 2.463287e-009
   maximum volume (m3): 4.508038e-007
    total volume (m3): 4.190433e-004
   minimum 2d volume (m3): 3.000589e-007
   maximum 2d volume (m3): 3.019523e-006
 Face area statistics:
   minimum face area (m2): 4.199967e-004
   maximum face area (m2): 2.434403e-003
 Checking mesh.....................
Done.
```

The mesh check report begins by listing the domain extents. The domain extents include the minimum and maximum x, y, and z coordinates in meters.

Then the volume statistics are provided, including the minimum, maximum, and total cell volume in m^3. A negative value for the minimum volume indicates that one or more cells have improper connectivity. Cells with a negative volume can often be identified and viewed by creating an iso-value field variable cell register (Field Variable (p. 3835)). You can try adapting the mesh to resolve the negative volume cells (Adapting the Mesh (p. 3755)). You *must* eliminate these negative volumes before continuing the flow solution process.

Next, the mesh report lists the face area statistics, including the minimum and maximum areas in m^2. A value of 0 for the minimum face area indicates that one or more cells have degenerated. As with negative volume cells, you *must* eliminate such faces. It is also recommended to correct cells that have nonzero face areas, if the values are very small.

Besides the information about the domain extents and statistics, the mesh check report will also display warnings based on the results of the checks previously described. You can specify that the mesh check report displays more detailed information about the various checks and the mesh failures, by using the following text command prior to performing the mesh check:

`mesh` → `check-verbosity`

You will then be prompted to enter the level of verbosity for the mesh check report. The possible levels include:

- `0`

  This is the default level, and only notifies you that checks are being performed (for example, **Checking mesh...**). The report will look like the previous example; while warnings will be displayed below the domain extents and statistics, the names of the individual checks will not be listed as they are conducted.

- `1`

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This level lists the individual checks as they are performed (for example, **Checking right-handed cells**). Any warnings that result will be displayed immediately below the check that produced it.

- 2

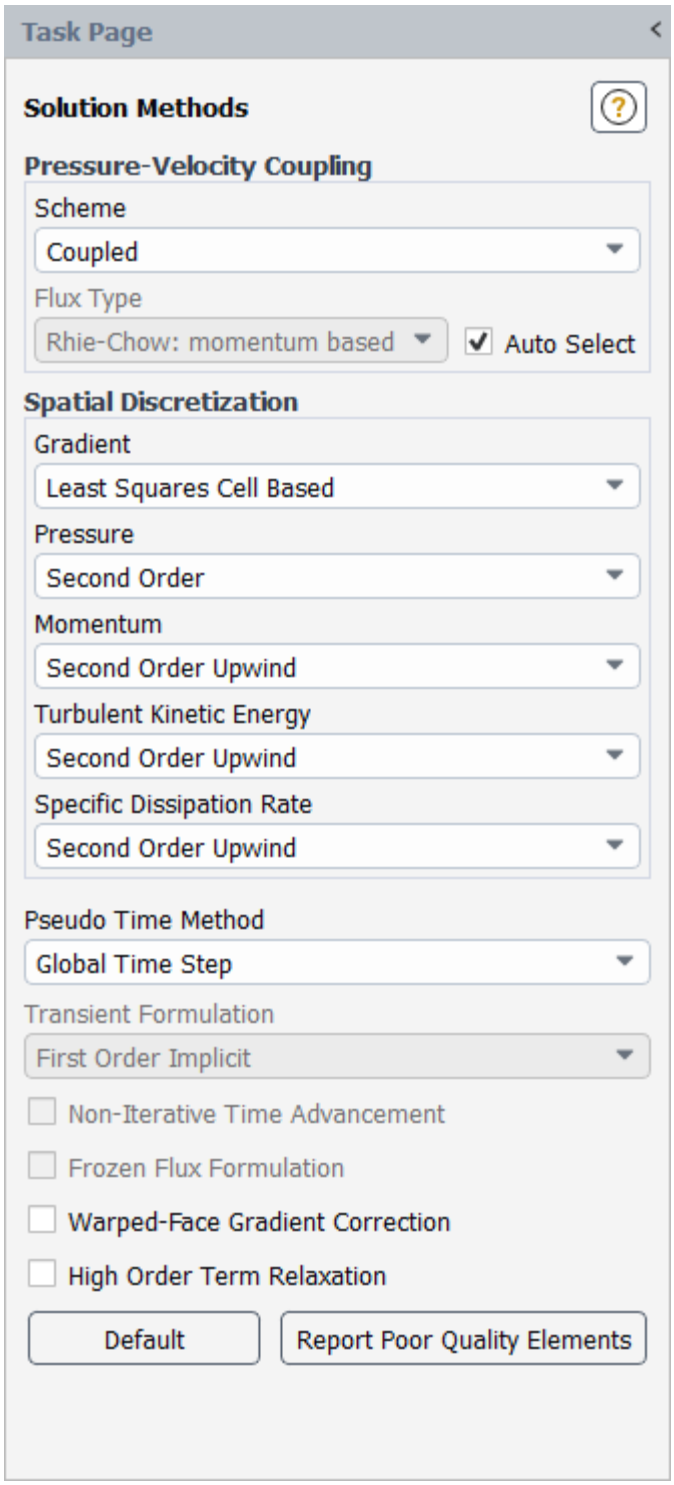
  This level provides the maximum information about the mesh check. The report will list the individual checks as they are performed (for example, **Checking right-handed cells**); any warnings that result will be displayed immediately below the check that produced it. Additional details about the check failure will also be displayed, such as the location of the problem or the affected cells.

6.9.2. Repairing Meshes

If the mesh check report indicates a mesh problem or if you receive warnings, you can investigate the extent of the problem by printing the poor element statistics in the console. This can be accomplished using the **Report Poor Quality Elements** button, located at the bottom of the **Solution Methods** task page (Figure 6.82: The Solution Methods Task Page (p. 1225)). Note that this button is only available when poor quality elements have been detected by the mesh check or have been marked for the application of poor mesh numerics (for details, see Robustness with Meshes of Poor Quality (p. 3727)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.82: The Solution Methods Task Page



Alternatively, you can print the poor element statistics via the following text command:

`mesh` → `repair-improve` → `report-poor-elements`

You can also visualize the invalid and poor elements by marking and displaying them by using the **Mesh...** and **Mark Poor Elements** selections from the **Field Value of** drop-down lists of the **Field Variable Register** dialog box (see Field Variable (p. 3835) for further details). Similarly, you can display

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

them using the **Contours** dialog box, by selecting **Mesh...** and **Mark Poor Elements** from the **Contours of** drop-down lists.

The solver variable can take a value of 1 to 6 and can be visualized:

- 1.0 user_defined_poor_elements
- 2.0 poor_quality_cells
- 3.0 modified_centroid_cells
- 4.0 cell adjacent to small_face_area
- 5.0 invalid_cells
- 6.0 solver_identified_poor_cells

By default 3.0, 4.0 and 5.0 are active. 2.0 is recommended.

The mesh check report will indicate if the mesh has problems that must be repaired, such as left-handed faces and/or faces that have the wrong node order. If repairable failures are detected by the mesh check, the **Repair** button in the **Domain** ribbon tab (**Mesh** group box) becomes available:

Domain → **Mesh** → **Repair**

Using the **Repair** button is the simplest way to attempt to correct your mesh problems. It will attempt to correct a number of problems identified by the mesh check, including cells that have:

- the wrong node order
- the wrong face handedness or that are not convex
- faces that are small or nonexistent
- very poor quality (see Mesh Quality (p. 1120) for additional details)

Note that by default, the **Repair** button will only adjust the positions of interior nodes. If you want to also modify the nodes on the boundaries of the mesh, use the following text command *before* you repair the mesh:

```
mesh → repair-improve → allow-repair-at-boundaries
```

The **Repair** button may convert degenerate cells into polyhedra, based on skewness criteria (for more information on how cells are converted, see Converting Skewed Cells to Polyhedra (p. 1235)). If you want to ensure that there are no polyhedra in the repaired mesh (for example, if you if plan on performing hanging node adaption), you must disable such conversions using the following text command *before* you repair the mesh:

```
mesh → repair-improve → include-local-polyhedra-conversion-in-repair
```

If you would like to only attempt to improve the poor quality cells, you can use the following text command:

```
mesh → repair-improve → improve-quality
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can use the `improve-quality` text command multiple times, until the mesh is improved to your satisfaction. For greater control over the degree to which the mesh is improved, you can perform quality-based smoothing (as described in Smoothing (p. 1268)).

It should be noted that both the **Repair** button and the `improve-quality` text command can be CPU intensive, if there are a large number of poor quality cells in the mesh. If you are not as concerned about cell quality, you can attempt to fix only the left-handed faces and faces with the wrong node order. Begin by repairing the node order with the following text command:

`mesh` → `repair-improve` → `repair-face-node-order`

Because the left-handed faces may be a result of improper face node order, the previous text command may resolve both issues at the same time. Be sure to perform another mesh check after entering the `repair-face-node-order` command, to see if the mesh has been fully repaired.

If at any point the mesh check reveals that the mesh contains left-handed faces without any node order issues, you can attempt to repair the face handedness by modifying the cell centroids with the following text command:

`mesh` → `repair-improve` → `repair-face-handedness`

Once again, perform a mesh check to see if the text command was successful. The `repair-face-handedness` text command is most effective for cells with high aspect ratios.

If the mesh check report includes a warning message such as

```
WARNING: node on face thread 2 has multiple shadows.
```

it indicates the existence of duplicate shadow nodes. This error occurs only in meshes with periodic-type walls. You can repair such a mesh using the following text command:

`mesh` → `repair-improve` → `repair-periodic`

If the interface is rotationally periodic, you will be prompted for the rotation angle.

6.10. Reporting Mesh Statistics

There are several methods for reporting information about the mesh after it has been read into Ansys Fluent. You can report the amount of memory used by the current problem, the mesh size, and statistics about the mesh partitions. Zone-by-zone counts of cells and faces can also be reported.

Information about mesh statistics is provided in the following sections:

6.10.1. Mesh Size
6.10.2. Memory Usage
6.10.3. Mesh Zone Information
6.10.4. Partition Statistics

6.10.1. Mesh Size

You can print out the numbers of nodes, faces, cells, and partitions in the mesh by clicking **Info** and selecting **Size**, in the **Domain** ribbon tab (**Mesh** group box).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Domain → Mesh → Info → Size

A partition is a piece of a mesh that has been segregated for parallel processing (see Parallel Processing (p. 4259)).

A sample of the resulting output follows:

```
Mesh Size

Level     Cells       Faces       Nodes        Partitions
    0      7917       12247       4468                1

2 cell zones, 11 face zones.
```

If you are interested in how the cells and faces are divided among the different zones, click **Info** and select **Zones**, in the **Domain** ribbon tab (**Mesh** group box), as described in Mesh Zone Information (p. 1229).

You can determine the number of faces at each boundary or at each boundary type by clicking **Info** in the context menu of the selected boundary or boundary type in the Outline View tree.

Setup → Boundary Conditions → <Boundary Type> → Info

If you are using the density-based coupled explicit solver, the mesh information will be printed for each grid level. The grid levels result from creating coarse grid levels for the FAS multigrid convergence acceleration (see Full-Approximation Storage (FAS) Multigrid in the Theory Guide). A sample of the resulting output is shown below:

```
Mesh Size

Level   Cells    Faces    Nodes     Partitions
 0       7917    12247     4468              1
 1       1347     3658        0              1
 2        392     1217        0              1
 3        133      475        0              1
 4         50      197        0              1
 5         17       78        0              1
2 cell zones, 11 face zones.
```

6.10.2. Memory Usage

During an Ansys Fluent session you may want to check the amount of memory used and allocated in the present analysis. Ansys Fluent has a feature that will report the following information: the numbers of nodes, faces, cells, edges, and object pointers (generic pointers for various mesh and graphics utilities) that are used and allocated; the amount of array memory (scratch memory used for surfaces) used and allocated; and the amount of memory used by the solver process.

You can obtain this information by clicking **Info** and selecting **Memory Usage**, in the **Domain** ribbon tab (**Mesh** group box).

Domain → Mesh → Info → Memory Usage

The memory information will be different for Linux and Windows systems.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.10.2.1. Linux Systems

On Linux systems, note the following definitions related to process memory information:

- Process static memory is essentially the size of the code itself.
- Process dynamic memory is the allocated heap memory used to store the mesh and solution variables.
- Process total memory is the sum of static and dynamic memory.

6.10.2.2. Windows Systems

On Windows systems, note the following definitions related to process memory information:

- Process physical memory is the allocated heap memory currently resident in RAM.
- Process virtual memory is the allocated heap memory currently swapped to the Windows system page file.
- Process total memory is the sum of physical and virtual memory.

Note the following:

- The memory information does not include the static (code) memory.
- Cortex runs in its own process, so the heap memory value includes storage for the mesh and solution variables only.

On Windows systems, you can also get more information on the Ansys Fluent process (or processes) by using the Task Manager (see your Windows documentation for details). Examples of process image names are as follows: `cx2410.exe` (Cortex), `fl2410.exe` (solver host), and `fl_mpi2410.exe` (solver node).

6.10.3. Mesh Zone Information

You can print information in the console about the nodes, faces, and cells in each zone the by clicking **Info** and selecting **Zones**, in the **Domain** ribbon tab (**Mesh** group box).

Domain → **Mesh** → **Info** → **Zones**

The mesh zone information includes the total number of nodes and, for each face and cell zone, the number of faces or cells, the cell (and, in 3D, face) type (triangular, quadrilateral, and so on), the boundary condition type, and the zone ID. Sample output is shown below:

```
Zone sizes on domain 1:
21280 hexahedral cells, zone 4.
  532 quadrilateral velocity-inlet faces, zone 1.
  532 quadrilateral pressure-outlet faces, zone 2.
  1040 quadrilateral symmetry faces, zone 3.
  1040 quadrilateral symmetry faces, zone 7.
 61708 quadrilateral interior faces, zone 5.
   1120 quadrilateral wall faces, zone 6.
23493 nodes.
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.10.4. Partition Statistics

You can print mesh partition statistics in the console by clicking **Info** and selecting **Partitions**, in the **Domain** ribbon tab (**Mesh** group box).

Domain → Mesh → Info → Partitions

The statistics include the numbers of cells, faces, interfaces, and neighbors of each partition. See Interpreting Partition Statistics (p. 4305) for further details, including sample output.

6.11. Converting the Mesh to a Polyhedral Mesh

Since the Ansys Fluent solver is face based, it supports polyhedral cells. The advantages that polyhedral meshes have shown over some of the tetrahedral or hybrid meshes is the lower overall cell count, almost 3-5 times lower for unstructured meshes than the original cell count. Currently, there are three options in Ansys Fluent that allow you to convert your non-polyhedral cells to a polyhedra:

- Converting the entire domain into polyhedral cells (applicable only for meshes that contain tetrahedral and/or wedge cells).
- Converting skewed tetrahedral cells to polyhedral cells.
- Converting cells with hanging nodes / edges to polyhedral cells.

Information about polyhedral mesh conversion is provided in the following sections:

6.11.1. Converting the Domain to a Polyhedra
6.11.2. Converting Skewed Cells to Polyhedra
6.11.3. Converting Cells with Hanging Nodes / Edges to Polyhedra

6.11.1. Converting the Domain to a Polyhedra

Conversion of a mesh to polyhedra only applies to 3D meshes that contain tetrahedral and/or wedge cells.

To begin the conversion process, Ansys Fluent automatically decomposes each non-hexahedral cell into multiple sub-volumes called “duals” (the shaded regions seen in the 2D example in Figure 6.83: Connection of Edge Centroids with Face Centroids (p. 1231)). Each dual is associated with one of the original nodes of the cell. These duals are then agglomerated into polyhedral cells around the original nodes. Therefore, the collection of duals from all cells sharing a particular node makes up each polyhedral cell (see Figure 6.84: A Polyhedral Cell (p. 1232)). The node that is now within the polyhedral cell is no longer needed and is removed.

To better understand how duals are formed, you can consider the straightforward case of a tetrahedral mesh. Each of the cells are decomposed in the following manner: first, new edges are created on each face between the face centroid and the centroids of the edges of that face. Then, new faces are created within the cell by connecting the cell centroid to the new edges on each face. These interior faces establish the boundaries between the duals of a cell, and divide the cell into 4 sub-volumes.

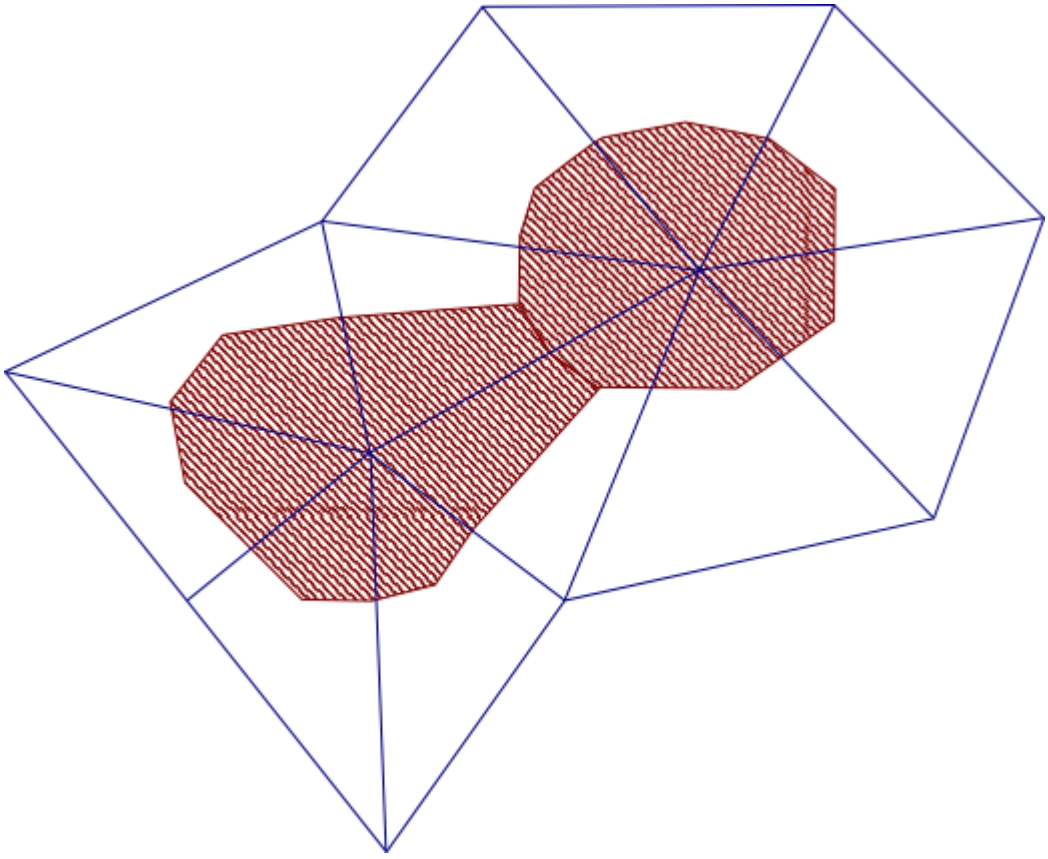
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

These dividing faces may be adjusted and merged with neighboring faces during the agglomeration process, in order to minimize the number of faces on the resultant polyhedral cell.

Note:

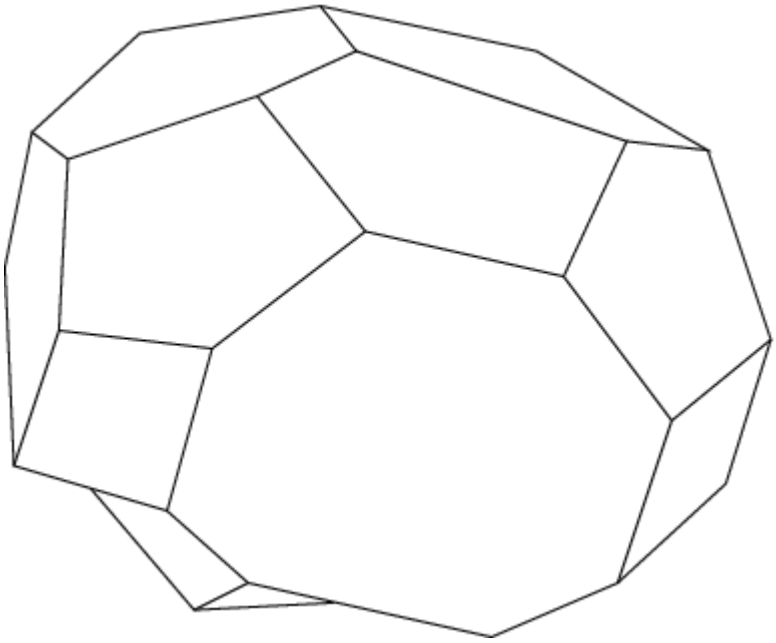
By default, Ansys Fluent checks the aspect ratio of boundary layer cells and if the aspect ratios are high, Ansys Fluent asks whether you want to preserve cells at the boundary layer (which could be useful for keeping cell counts low when retaining boundary features). You can override this default with the text command: `mesh/polyhedra/options/preserve-boundary-layer?` (for additional information about these options, see `mesh/` in the *Fluent Text Command List*).

Figure 6.83: Connection of Edge Centroids with Face Centroids



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

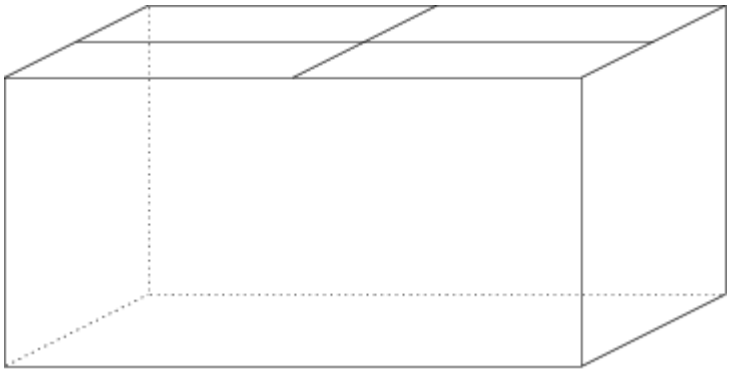
Figure 6.84: A Polyhedral Cell



Important:

Hexahedral cells are not converted to polyhedra when the domain is converted, except when they border non-hexahedral cells. When the neighboring cell is reconfigured as polyhedra, the shared face of the hexahedral cell is decomposed into multiple faces as well, resulting in a polyhedral cell. In such a case the shape of the original hexahedral cell is preserved (that is the overall dimensions of the cell stay the same), but the converted cell has more than the original 6 faces (see Figure 6.85: A Converted Polyhedral Cell with Preserved Hexahedral Cell Shape (p. 1232)).

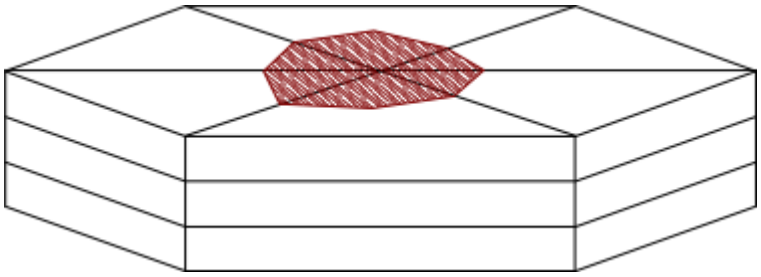
Figure 6.85: A Converted Polyhedral Cell with Preserved Hexahedral Cell Shape



Conversion proceeds in a slightly different manner in boundary layers that are modeled using thin wedge cells. These cells are decomposed in the plane of the boundary surface, but not in the direction normal to the surface. The resulting polyhedra will therefore preserve the thickness of the original wedge cells (Figure 6.86: Treatment of Wedge Boundary Layers (p. 1233)). In most cases, the cell count in the new polyhedral boundary layer will be lower than the original boundary layer.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.86: Treatment of Wedge Boundary Layers



To convert the entire domain of your mesh, click **Make Polyhedra** in the **Domain** ribbon tab (**Mesh** group box).

Domain → Mesh → Make Polyhedra

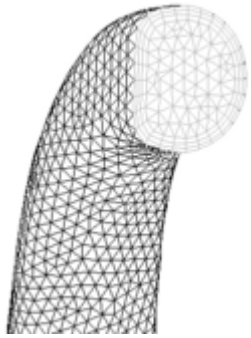
The following is an example of the resulting message printed in the console:

```
 Setup conversion to polyhedra.
 Converting domain to polyhedra...

      Creating polyhedra zones.
      Processing face zones..........
      Processing cell zones...
      Building polyhedra mesh..................
      Optimizing polyhedra mesh.....
>> Reordering domain using Reverse Cuthill-McKee method:
    zones, cells, faces, done.
 Bandwidth reduction = 1796/247 = 7.27
 Done.
```

Figure 6.87: The Original Tetrahedral Mesh (p. 1233), the original tetrahedral mesh of a section of a manifold, is compared to Figure 6.88: The Converted Polyhedral Mesh (p. 1234), which is the resulting mesh after the entire domain is converted to a polyhedra.

Figure 6.87: The Original Tetrahedral Mesh



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.88: The Converted Polyhedral Mesh

Note that by default, the surfaces (that is, manifold zones of type **interior**) will be lost during the conversion to polyhedra. If you would like to preserve any of these zones (in order to utilize them for postprocessing, for example), use the following text command prior to the conversion:

`mesh` → `polyhedra` → `options` → `preserve-interior-zones`

You will be prompted to enter a string of characters, and only those interior surfaces with a name that includes the string you specify will be preserved.

In parallel, a new partitioning will be stored after the conversion, but by default these new partitions will not be made active (that is, migrated to the compute-nodes) as this requires significant additional memory. The new partitions will be saved with the case file and used automatically when it is opened in a new Fluent session; it is recommended that you then manually reorder the domain prior to calculating (using the `mesh/reorder/reorder-domain` text command). If you want to use the new partitions in the current Fluent session, you should first ensure that no more than half of the available memory of this system is currently used, and then you can manually migrate the partitions (using the `parallel/partition/use-stored-partitions` text command) and reorder. If you know prior to conversion that you will want to calculate a solution in the same session (and you have sufficient memory), you can enable the following text command, so that the migration and reordering is performed automatically as part of the conversion:

`mesh` → `polyhedra` → `options` → `migrate-and-reorder?`

6.11.1.1. Limitations

Some limitations you will find with polyhedral meshes that you generally do not experience with other cell types include:

- Meshes that already contain polyhedral cells cannot be converted.
- Meshes with hanging nodes / edges will not be converted. This includes meshes that have undergone hanging node adaption (see Hanging Node Adaption in the Theory Guide), as well as CutCell meshes and hexcore meshes (generated when using the **Hex Core** meshing scheme in GAMBIT or the **Hexcore** menu option in the meshing mode of Fluent) which you have read after disabling the automatic conversion of hanging nodes / edges (see Converting Cells with Hanging Nodes / Edges to Polyhedra (p. 1236) for details).
- The following mesh manipulation tools are not available for polyhedral meshes:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

  - the `mesh/modify-zones/extrude-face-zone-delta` text command
  - the `mesh/modify-zones/extrude-face-zone-para` text command
  - skewness smoothing
  - swapping

- Meshes in which the domain has been converted to polyhedral cells are not eligible for adaption with the hanging node method, though they can be refined with the default polyhedral unstructured mesh adaption (PUMA) method. For more information about adaption, see Adapting the Mesh (p. 3755).

- A mesh that is composed entirely of polyhedral cells has limitations when used in a dynamic mesh problem: it cannot undergo remeshing. Smoothing is allowed for polyhedral cells, and radial basis function smoothing is the recommended method (see Radial Basis Function Smoothing (p. 1798) for details). The linearly elastic solid smoothing method is not compatible with polyhedral cells.

- Since polyhedral meshes can have a much higher ratio of nodes to cells then tet or hex meshes, the use of the node-based gradient method may result in a significant increase in memory consumption compared with other gradient methods.

6.11.2. Converting Skewed Cells to Polyhedra

Another method of cell agglomeration is the skewness-based cluster approach. This type of conversion is designed to convert only part of the domain. The objective is to convert only skewed tetrahedral cells above a specified cell equivolume skewness threshold into polyhedra. By converting the highly skewed tetrahedral cells, the quality of the mesh can be improved significantly.

A different algorithm is used for local conversion. This algorithm evaluates each highly skewed tetrahedral cell and all of the surrounding cells, to select an edge on the highly skewed cell that best matches criteria for cell agglomeration. Then all of the cells that share this edge are combined into a polyhedral cell. During the process, the data is interpolated from the original cells to the resultant polyhedra.

6.11.2.1. Limitations

There are certain limitations with this type of conversion:

- The following mesh manipulation tools are not available on polyhedral meshes:
  - the `mesh/modify-zones/extrude-face-zone-delta` text command
  - the `mesh/modify-zones/extrude-face-zone-para` text command
  - skewness smoothing
  - swapping will not affect polyhedral cells

- The polyhedral cells that result from the conversion are not eligible for adaption with the hanging node method, though they can be refined with the default polyhedral unstructured mesh adaption (PUMA) method. For more information about adaption, see Adapting the Mesh (p. 3755).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Only tetrahedral cells are converted, as all other cells are skipped.
- Meshes with hanging nodes / edges will not be converted. This includes meshes that have undergone hanging node adaption (see Hanging Node Adaption in the Theory Guide), as well as CutCell meshes and hexcore meshes (generated when using the **Hex Core** meshing scheme in GAMBIT or the **Hexcore** menu option in the meshing mode of Fluent) which you have read after disabling the automatic conversion of hanging nodes / edges (see Converting Cells with Hanging Nodes / Edges to Polyhedra (p. 1236) for details). Note that if the mesh is a CutCell / hexcore mesh in which the transitional cells have been converted to polyhedra, then it does not have hanging nodes / edges and can therefore be converted.
- Note the following with regard to the polyhedral cells that result from this conversion and the update methods available for dynamic mesh problems:
  - None of the remeshing methods will modify polyhedral cells.
  - Smoothing is allowed for polyhedral cells, and radial basis function smoothing is the recommended method (see Radial Basis Function Smoothing (p. 1798) for details). The linearly elastic solid smoothing method is not compatible with polyhedral cells.

6.11.3. Converting Cells with Hanging Nodes / Edges to Polyhedra

3D meshes that contain hanging nodes or hanging edges are by default converted when the file is read, so that the cells adjacent to the hanging nodes / edges become polyhedra. Each cell that is converted will retain the same overall dimensions, but the number of faces associated with the cell may increase (see Figure 6.85: A Converted Polyhedral Cell with Preserved Hexahedral Cell Shape (p. 1232) for an example). Such a conversion may be helpful for CutCell meshes, as well as hexcore meshes (generated when using the **Hex Core** meshing scheme in GAMBIT or the **Hexcore** menu option in the meshing mode of Fluent), and may prevent errors associated with interior walls (see Removing Hanging Nodes / Edges (p. 1133)). You can opt to disable this conversion by using the following text command prior to reading: `file/convert-hanging-nodes-during-read? no`.

Ansys Fluent also provides a text command that allows you to convert 3D cells that have hanging nodes / edges into polyhedra after reading. For example, you may want to convert the cells with hanging nodes in a mesh that has undergone hanging node adaption (see Adapting the Mesh (p. 3755)); note that you want to be sure that no further refinement / coarsening of the mesh will be necessary. To convert the cells with hanging nodes / edges after reading, use the following text command:

`mesh` → `polyhedra` → `convert-hanging-nodes`

6.11.3.1. Limitations

There are certain limitations with this type of conversion:

- The following mesh manipulation tools are not available on polyhedral meshes:
  - the `mesh/modify-zones/extrude-face-zone-delta` text command
  - the `mesh/modify-zones/extrude-face-zone-para` text command
  - skewness smoothing
  - swapping will not affect polyhedral cells

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The polyhedral cells that result from the conversion are not eligible for adaption with the hanging node method, though they can be refined with the default polyhedral unstructured mesh adaption (PUMA) method. For more information about adaption, see Adapting the Mesh (p. 3755).
- Note the following with regard to the polyhedral cells that result from this conversion and the update methods available for dynamic mesh problems:
  - None of the remeshing methods will modify polyhedral cells.
  - Smoothing is allowed for polyhedral cells, and radial basis function smoothing is the recommended method (see Radial Basis Function Smoothing (p. 1798) for details). The linearly elastic solid smoothing method is not compatible with polyhedral cells.

6.12. Modifying the Mesh

There are several ways in which you can modify or manipulate the mesh after it has been read into Ansys Fluent. You can scale, translate, or rotate the mesh / zones, copy, merge, or separate zones, create or decouple periodic zones, fuse boundaries, and smooth and swap faces. Methods for partitioning meshes to be used in a parallel solver are discussed in Mesh Partitioning and Load Balancing (p. 4281).

Important:

Whenever you modify the mesh, you should be sure to save a new case file (and a data file, if data exists). If you have old data files that you would like to be able to read in again, be sure to retain the original case file as well, as the data in the old data files may not correspond to the new case file.

Information about mesh manipulation is provided in the following sections:

6.12.1. Merging Zones
6.12.2. Separating Zones
6.12.3. Fusing Face Zones
6.12.4. Creating Periodic Zones and Interfaces

6.12.18. Boundary Layer Redistribution

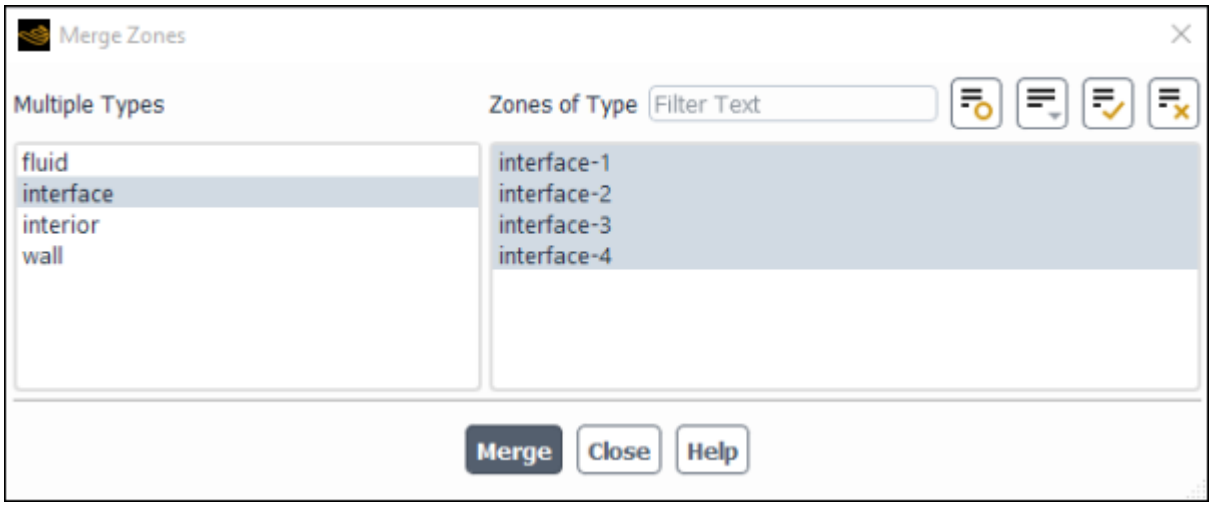
6.12.1. Merging Zones

To simplify the solution process, you may want to merge zones. Merging zones involves combining multiple zones of similar type into a single zone. Setting boundary conditions and postprocessing may be easier after you have merged similar zones.

Zone merging is performed in the Merge Zones Dialog Box (p. 5467) (Figure 6.89: The Merge Zones Dialog Box (p. 1238)).

Domain → Zones → Combine → Merge...

Figure 6.89: The Merge Zones Dialog Box



6.12.1.1. When to Merge Zones

Ansys Fluent allows you to merge zones of similar type into a single zone. This is not necessary unless the number of zones becomes prohibitive to efficient setup or postprocessing of the numerical analysis. For example, setting the same boundary condition parameters for a large number of zones can be time-consuming and may introduce inconsistencies. In addition, the postprocessing of the data often involves surfaces generated using the zones. A large number of zones often translates into a large number of surfaces that must be selected for the various display options, such as color contouring. Fortunately, surfaces can also be merged (see Grouping, Prioritizing, Editing, Renaming, and Deleting Surfaces (p. 3827)), minimizing the negative impact of a large number of zones on postprocessing efficiency.

Although merging zones can be helpful, there may be cases where you will want to retain a larger number of zones. Since the merging process is not fully reversible, a larger number of zones provides more flexibility in imposing boundary conditions. Although a large number of zones can make selection of surfaces for display tedious, it can also provide more choices for rendering the mesh and the flow-field solution. For instance, it can be difficult to render an internal flow-field solution. If the outer domain is composed of several zones, the meshes of subsets of these zones can be plotted along with the solution to provide the relationship between the geometry and solution field. Merging zones may also adversely affect dynamic zones and mesh interfaces.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.12.1.2. Using the Merge Zones Dialog Box

The procedure for merging multiple zones of the same type into a single zone is as follows:

1. Select the zone type in the **Multiple Types** list. This list contains all the zone types for which there are multiple zones. When you choose a type from this list, the corresponding zones will appear in the **Zones of Type** list.
2. Select two or more zones in the **Zones of Type** list.
3. Click the **Merge** button to merge the selected zones. Note that if your case file has dynamic zones or mesh interfaces, the **Warning** dialog box will open before the merge is initiated, allowing you to specify whether you want to delete such zones or interfaces first (see Warning Dialog Box (p. 5604) for details).

Important:

Remember to save a new case file (and a data file, if data exists).

6.12.2. Separating Zones

Upon reading a mesh file, Ansys Fluent automatically performs zone separations in two conditions. If a face zone is attached to multiple cells zones in the preprocessor, the face zone will be separated so that each one is attached to only one cell zone. Furthermore, if you have defined an internal face as a wall type, an additional shadow wall zone will be generated (for example, for a wall named **baffle**, a shadow wall zone named **baffle-shadow** will be generated).

There are several methods available in Ansys Fluent that allow you to manually separate a single face or cell zone into multiple zones of the same type. If your mesh contains a zone that you want to break up into smaller portions, you can make use of these features. For example, if you created a single wall zone when generating the mesh for a duct, but you want to specify different temperatures on specific portions of the wall, you will need to break that wall zone into two or more wall zones. If you plan to solve a problem using the sliding mesh model or multiple reference frames, but you forgot to create different fluid zones for the regions moving at different speeds, you will need to separate the fluid zone into two or more fluid zones.

Important:

- After performing any of these separations, you should save a new case file. If data exists, it is automatically assigned to the proper zones when separation occurs, so you should also write a new data file. The old data cannot be read on top of the case file in which the zones have changed.
- The maximum number of zones into which you can separate any one face zone or cell zone is 32.

There are four ways to separate face zones and two ways to separate cell zones. The face separation methods will be described first, followed by the cell separation tools. Decoupling of periodic zones is discussed in Decoupling Periodic Zones (p. 1249).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note that all of the separation methods allow you to report the result of the separation before you commit to performing it.

6.12.2.1. Separating Face Zones

For more information, see the following sections:

6.12.2.1.1. Methods for Separating Face Zones

6.12.2.1.2. Inputs for Separating Face Zones

6.12.2.1.1. Methods for Separating Face Zones

For geometries with sharp corners, it is often easy to separate face zones based on significant angle. Faces with normal vectors that differ by an angle greater than or equal to the specified significant angle will be placed in different zones. For example, if your mesh consists of a cube, and all 6 sides of the cube are in a single wall zone, you would specify a significant angle of 89°. Since the normal vector for each cube side differs by 90° from the normals of its adjacent sides, each of the 6 sides will be placed in a different wall zone.

If you have a small face zone and would like to put each face in the zone into its own zone, you can do so by separating the faces based on face. Each individual face (triangle, quad, or polygon) will be separated into different zones.

You can also separate face zones based on cell registers. For example, you can mark cells based on their location in the domain (region register), their boundary closeness (boundary register), field values of some variable, or any of the cell marking methods discussed in Using Cell Registers (p. 3831). When you specify which register is to be used for the separation of the face zone, all faces of cells that are marked will be placed into a new face zone.

Finally, you can separate face zones based on contiguous regions. For example, when you use coupled wall boundary conditions you need the faces on the zone to have a consistent orientation. Consistent orientation can only be guaranteed on contiguous regions, so you may need to separate face zones to allow proper boundary condition specification.

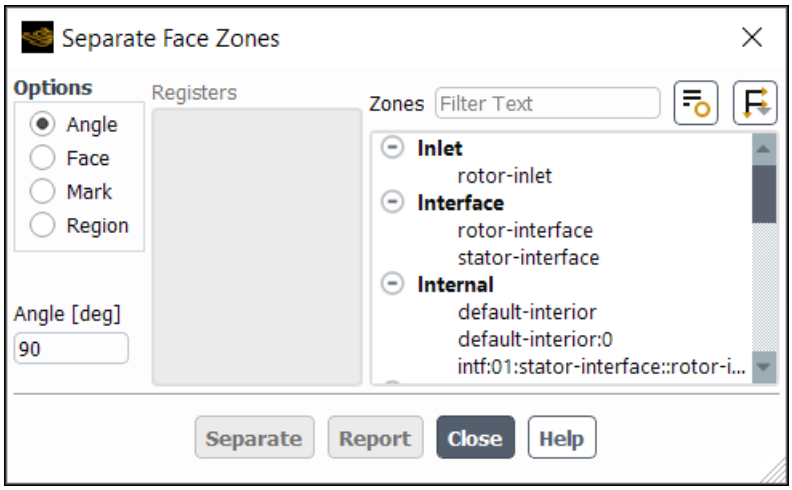
6.12.2.1.2. Inputs for Separating Face Zones

To break up a face zone based on angle, face, cell register mark, or region, use the Separate Face Zones Dialog Box (p. 5548) (Figure 6.90: The Separate Face Zones Dialog Box (p. 1241)).

Domain → **Zones** → **Separate** → **Faces...**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.90: The Separate Face Zones Dialog Box



Important:

If you are planning to separate face zones, you should do so before performing any adaptions using the hanging node adaption method. Face zones that contain hanging nodes cannot be separated.

The steps for separating faces are as follows:

1. Select the separation method (**Angle**, **Face**, **Mark**, or **Region**) under **Options**.
2. Specify the face zone to be separated in the **Zones** list.
3. If you are separating by face or region, skip to the next step. Otherwise, do one of the following:
   - If you are separating faces by angle, specify the significant angle in the **Angle** field.
   - If you are separating faces by mark, select the cell register to be used in the **Registers** list.
4. (optional) To check what the result of the separation will be before you actually separate the face zone, click the **Report** button. The report will look like the following example:

```
45 faces in contiguous region 0
30 faces in contiguous region 1
11 faces in contiguous region 2
14 faces in contiguous region 3
Separates zone 4 into 4 zone(s).
```

5. To separate the face zone, click the **Separate** button. A report will be printed in the console like the following example:

```
45 faces in contiguous region 0
30 faces in contiguous region 1
11 faces in contiguous region 2
14 faces in contiguous region 3
Separates zone 4 into 4 zone(s).
Updating new zone information ...
   created new zone wall-4:001 from wall-4
   created new zone wall-4:002 from wall-4
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
   created new zone wall-4:010 from wall-4
done.
```

Important:

When you separate the face zone by cell register mark, you may sometimes find that a face of a corner cell will be placed in the wrong face zone. You can usually correct this problem by performing an additional separation, based on angle, to move the offending face to a new zone. You can then merge this new zone with the zone in which you want the face to be placed, as described in Merging Zones (p. 1238).

6.12.2.2. Separating Cell Zones

For more information, see the following sections:

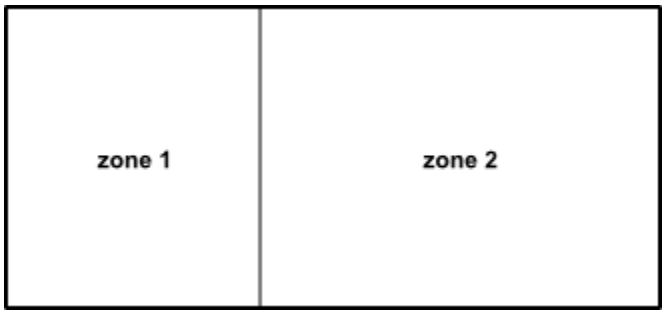
6.12.2.2.1. Methods for Separating Cell Zones

6.12.2.2.2. Inputs for Separating Cell Zones

6.12.2.2.1. Methods for Separating Cell Zones

If you have two or more enclosed cell regions sharing internal boundaries (as shown in Figure 6.91: Cell Zone Separation Based on Region (p. 1242)), but all of the cells are contained in a single cell zone, you can separate the cells into distinct zones using the separation-by-region method. Note that if the shared internal boundary is of type **interior**, you must change it to another double-sided face zone type (**fan**, **radiator**, and so on) prior to performing the separation.

Figure 6.91: Cell Zone Separation Based on Region



You can also separate cell zones based on the marks stored in cell registers. You can mark cells using any of the methods discussed in Using Cell Registers (p. 3831) (for example, you can mark cells with a certain field value range or cells inside or outside a specified region). When you specify which register is to be used for the separation of the cell zone, cells that are marked will be placed into a new cell zone.

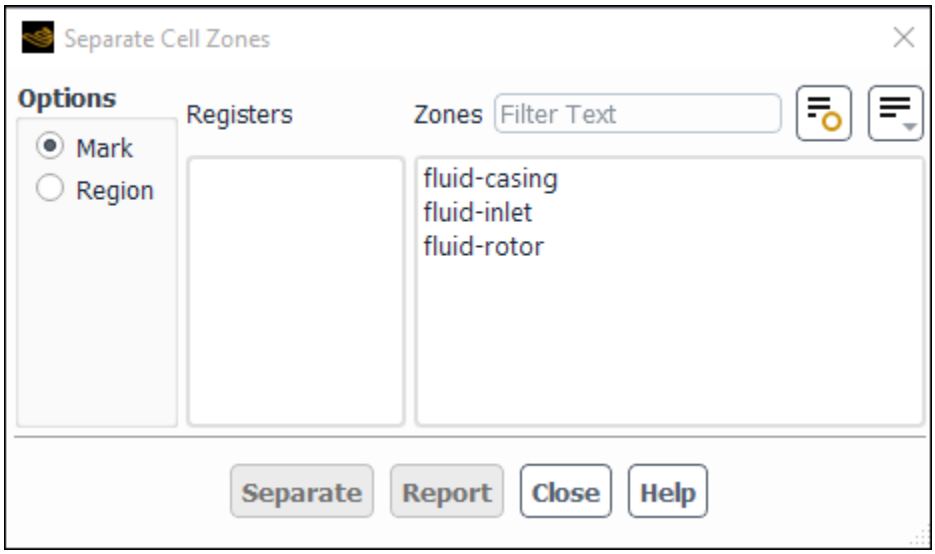
6.12.2.2.2. Inputs for Separating Cell Zones

To break up a cell zone based on region or cell register mark, use the Separate Cell Zones Dialog Box (p. 5547) (Figure 6.92: The Separate Cell Zones Dialog Box (p. 1243)).

Domain → **Zones** → **Separate** → **Cells...**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.92: The Separate Cell Zones Dialog Box



Important:

If you are planning to separate cell zones, you should do so before performing any adaptions using the hanging node adaption method. Cell zones that contain hanging nodes cannot be separated.

The steps for separating cells are as follows:

1. Select the separation method (**Mark** or **Region**) under **Options**.
2. Specify the cell zone to be separated in the **Zones** list.
3. If you are separating cells by mark, select the cell register to be used in the **Registers** list.
4. (optional) To check what the result of the separation will be before you actually separate the cell zone, click the **Report** button. The report will look like this:

```
Separates zone 14 into two zones, with 1275 and 32 cells.
```

5. To separate the cell zone, click the **Separate** button. Ansys Fluent will print the following information:

```
Separates zone 14 into two zones, with 1275 and 32 cells.
No faces marked on thread, 2
No faces marked on thread, 3
No faces marked on thread, 1
No faces marked on thread, 5
No faces marked on thread, 7
No faces marked on thread, 8
No faces marked on thread, 9
No faces marked on thread, 61
Separates zone 62 into two zones, with 1763 and 58 faces.
All faces marked on thread, 4
No faces marked on thread, 66
Moved 32 cells from cell zone 14 to zone 10
Updating new zone information ...
   created new zone interior-4:010 from interior-4
   created new zone interior-6:009 from interior-6
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
   created new zone fluid-14:008 from fluid-14
done.
```

As shown in the example above, separation of a cell zone will often result in the separation of face zones as well. When you separate by mark, faces of cells that are moved to a new zone will be placed in a new face zone. When you separate by region, faces of cells that are moved to a new zone will not necessarily be placed in a new face zone.

If you find that any faces are placed incorrectly, see the comment above, at the end of the inputs for face zone separation.

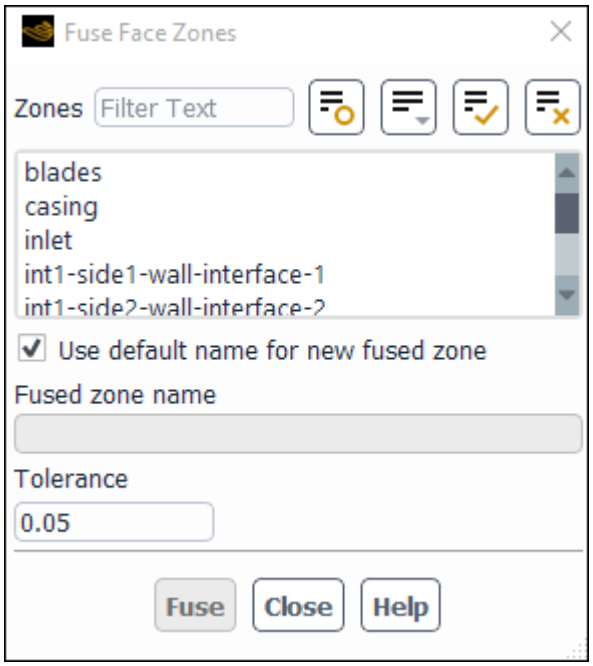
6.12.3. Fusing Face Zones

The face-fusing utility is a convenient feature that can be used to fuse boundaries (and merge duplicate nodes and faces) created by assembling multiple mesh regions. When the domain is divided into subdomains and the mesh is generated separately for each subdomain, you will combine the subdomains into a single file before reading the mesh into Fluent. For details, see Reading Multiple Mesh/Case/Data Files (p. 1135). This situation could arise if you generate each block of a multiblock mesh separately and save it to a separate mesh file. Another possible scenario is that you decided, during mesh generation, to save the mesh for each part of a complicated geometry as a separate part file. (Note that the mesh node locations need not be identical at the boundaries where two subdomains meet; see Non-Conformal Meshes (p. 1149) for details.)

The **Fuse Face Zones** dialog box (Figure 6.93: The Fuse Face Zones Dialog Box (p. 1244)) allows you to merge the duplicate nodes and delete these artificial internal boundaries.

Domain → Zones → Combine → Fuse...

Figure 6.93: The Fuse Face Zones Dialog Box



The boundaries on which the duplicate nodes lie are assigned zone ID numbers (just like any other boundary) when the mesh files are combined, as described in Reading Multiple Mesh/Case/Data

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Files (p. 1135). You need to keep track of the zone ID numbers when `tmerge` or the meshing mode of Fluent reports its progress or, after the complete mesh is read in, display all boundary mesh zones and use the mouse-probe button to determine the zone names (see Controlling the Mouse Button Functions (p. 3989) for information about the mouse button functions). Alternatively, you can specify a name for the fused zone.

Note:

For adapted meshes, fusing of face zones is only possible in serial with the PUMA adaption method (which is the default method for 3D).

6.12.3.1. Inputs for Fusing Face Zones

The steps for fusing face zones are as follows:

1. Select the zones to be fused in the **Zones** list.

   Important:

   When using the Fuse Face Zone utility, each of the selected face zones must be fused in its entirety with another face zone having the same connectivity. Partial fusing of face zones is not supported.

2. (Optional) If you would like to specify a name for the fused zone rather than use an automatically generated name (for instance, to preserve the original name of one of the face zones), disable **Use default name for new fused zone** and enter the desired name.

3. Click the **Fuse** button to fuse the selected zones.

If all of the appropriate faces do not get fused using the default **Tolerance**, you should increase it and attempt to fuse the zones again. (This tolerance is the same as the matching tolerance discussed in Creating Periodic Zones and Interfaces (p. 1246).) The **Tolerance** should not exceed 0.5, or you may fuse the wrong nodes.

You can also fuse zones using the `mesh/modify-zones/fuse-face-zones` text command, as shown in the following example.

```
/mesh/modify-zones > fuse-face-zones

()
Zone to fuse(1) [()]  w1.top

Zone to fuse(2) [()]  w3

Zone to fuse(3) [()]  [Enter]

Choose from list (automatic w3 w1.top) or pick your own
Enter the fused zone name: [automatic]  w3

  Name of zone 14 is changed into w3.
```

```
Fused list of zones successfully.
```

Important:

Remember to save a new case file (and a data file, if data exists) after fusing faces.

6.12.3.1.1. Fusing Zones on Branch Cuts

Meshes imported from structured mesh generators or solvers (such as FLUENT 4) can often be O-type or C-type meshes with a reentrant branch cut where coincident duplicate nodes lie on a periodic boundary. Since Ansys Fluent uses an unstructured mesh representation, there is no reason to retain this artificial internal boundary. (You can preserve these periodic boundaries and the solution algorithm will solve the problem with periodic boundary conditions.)

To fuse this periodic zone with itself, you must first decouple the periodic zone, as described in Decoupling Periodic Zones (p. 1249). This will create two symmetry zones that you can fuse using the procedure above.

Note that if you need to fuse portions of a non-periodic zone with itself, you must use the `mesh/modify-zones/fuse-face-zones` text command.

`mesh` → `modify-zones` → `fuse-face-zones`

This command will prompt you for the name or ID of each zone to be fused. (You will enter the same zone twice.) To change the node tolerance, use the `mesh/modify-zones/matching-tolerance` text command.

6.12.4. Creating Periodic Zones and Interfaces

Ansys Fluent allows you to assign periodicity to your mesh by coupling a pair of face zones. If the two zones are conformal (that is, have identical node and face distributions), then you can change them to be a pair of coupled zones that are both of type **periodic**. If the two zones are not identical at the boundaries within a specified tolerance, then you can change them both to be of type **interface** and include them in a non-conformal mesh interface that is periodic.

Important:

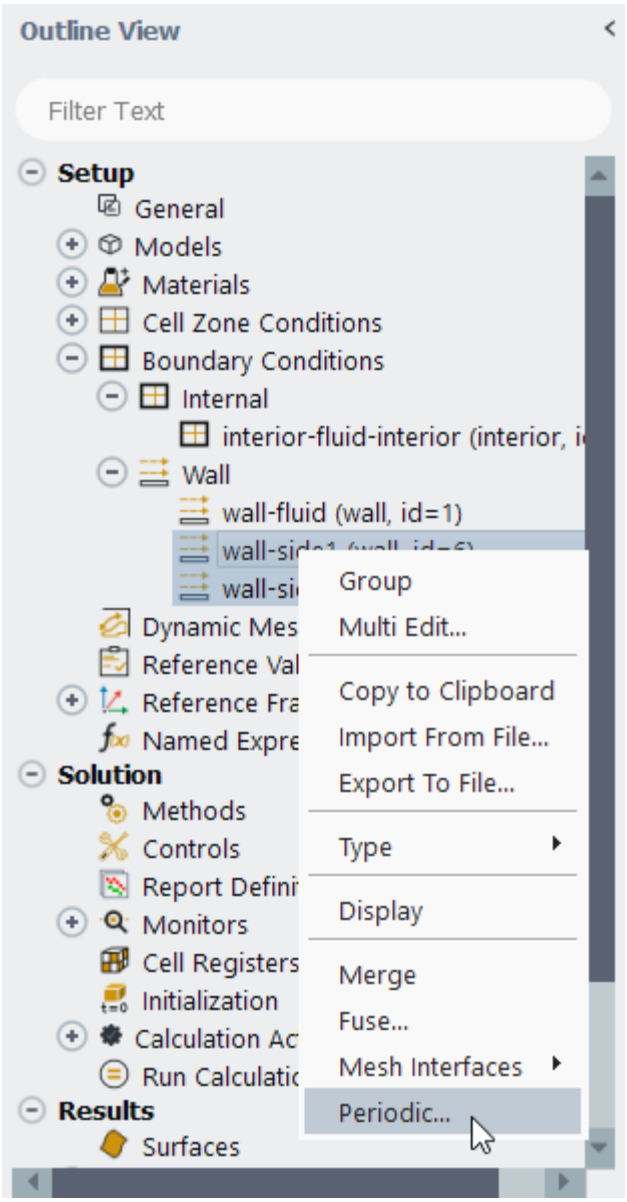
Remember to save a new case file (and a data file, if data exists) after creating or decoupling a periodic boundary pair.

To create a periodic boundary zone pair or interface, perform the following steps:

1. Select the two boundary zones that make up the periodic pair in the Outline View (under **Setup**/**Boundary Conditions**). Note that you can select multiple zones by holding the **Ctrl** key while selecting. The zones cannot be of type **interior** or **periodic**. The order of selection will not affect the calculation results, though it may affect the naming: for conformal pairings, the first zone you select is considered the primary zone of the pair and will be renamed according to your specifications (while the second zone you select is considered the shadow zone).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

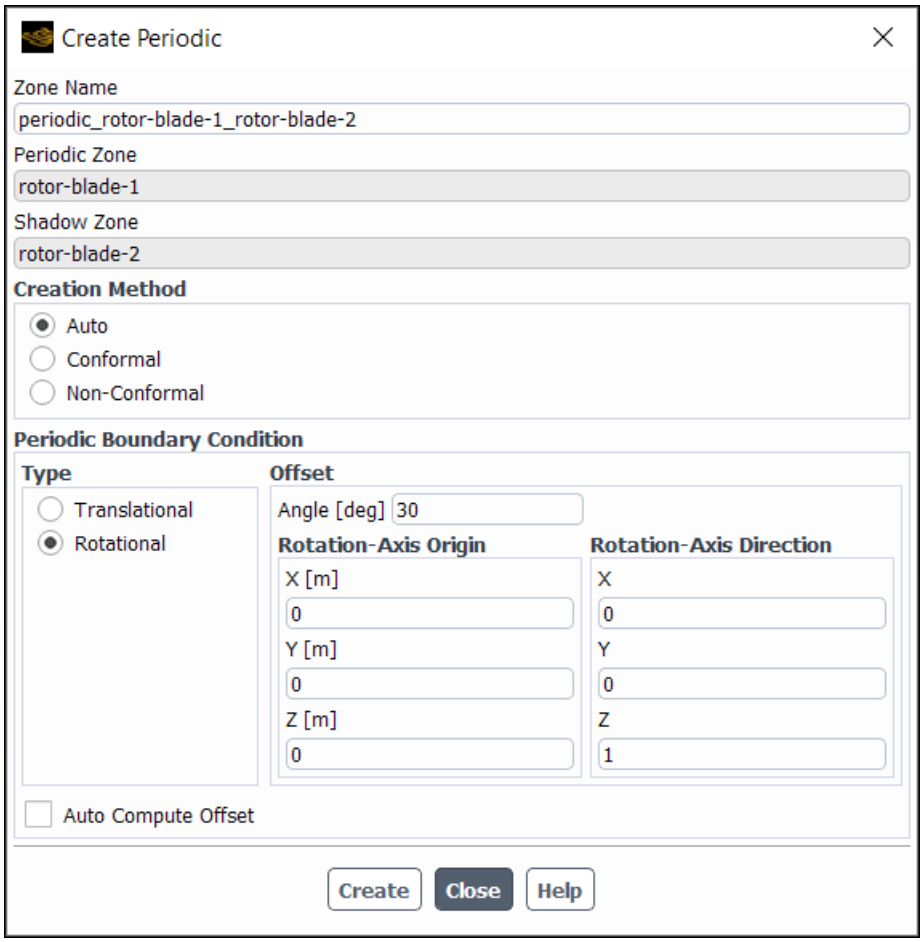
2. Right-click one of the selected zones and select **Periodic...** from the menu that opens, in order to open the **Create Periodic** dialog box.



3. Perform the following steps in the **Create Periodic** dialog box.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.94: The Create Periodic Dialog Box



a. Enter a **Zone Name**. For conformal pairings, the first boundary zone you selected in step 1. is considered the primary zone and will be renamed with this **Zone Name** during the creation process; for non-conformal pairings, this **Zone Name** will be used for both the resulting mesh interface and a single periodic boundary zone.

b. Make a selection from the **Creation Method** list to indicate whether the face zones that make up the periodic pair are **Conformal** or **Non-Conformal**. If you are unsure, you can select **Auto** and Fluent will automatically handle this decision (in which case a conformal pairing will be used if possible).

Note:

For pairings that are non-conformal, the resulting periodic mesh interface will use the **Matching** option by default. For details about the **Matching** option, see Matching Option (p. 1156).

---

c. Define the settings in the **Periodic Boundary Condition** group box:

- Select either **Translational** or **Rotational** from the **Type** list to define the type of periodicity for the pairing.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Retain the enabled default setting of **Auto Compute Offset** if you want Ansys Fluent to automatically compute the translational offset or the angle of the rotational offset. Otherwise, you can disable the **Auto Compute Offset** option and manually enter values to define the offset.

  Important:

  When using auto computation for 3D cases, you should ensure that the mesh resolution on the periodic interface zone pairs are similar if both of the following conditions are met: the periodic interface zone pairs are not planar; and they are not connected by at least two face zones that meet at an edge that points from one periodic zone to the other. In such situations, having a similar mesh resolution will produce more precise offset calculations (and subsequently, more accurate solutions). It is recommended that the average mesh size on one boundary should not be more than twice that of the other.

- For rotationally periodic pairings, enter values for the **Rotation-Axis Origin** and the **Rotation-Axis Direction**. Note that auto computation of the offset does not mean that these fields are also detected automatically and updated.

d. Click **Create** to create the periodic pairing. If it is a conformal pairing, the face zones are both changed to be of type **periodic**; the primary zone is renamed according to your specified **Zone Name**, and the shadow zone will retain its original name or (if it uses a default name) will be renamed automatically to reflect the new type (as described in Changing Cell and Boundary Zone Types (p. 1279)). If it is a non-conformal pairing, both face zones are changed to be of type **interface**, and a face zone of type **periodic** and a mesh interface is created.

4. When attempting to create a conformal periodic boundary zone pair, Fluent will check to see if the faces on the selected zones "match" (that is, whether or not the nodes on corresponding faces are coincident). The matching tolerance for a face is a fraction of the minimum edge length of the face. If the creation of a conformal periodic boundary zone pair fails, you can change the matching tolerance using the following text command. The tolerance should not exceed 0.5, or you may match up the periodic zones incorrectly and corrupt the mesh.

   `mesh` → `modify-zones` → `matching-tolerance`

5. When using the density-based solver, you can specify a pressure jump for a conformal periodic zone pair; for details, see Periodic Flows (p. 1719).

Note that the functionality of the **Create Periodic** dialog box can also be accessed through the `define/boundary-conditions/modify-zones/create-periodic-interface` text command.

For more information about non-conformal periodic boundaries and an alternate way to create them, see Non-Conformal Meshes (p. 1149) and Using a Non-Conformal Mesh in Ansys Fluent (p. 1164), respectively.

6.12.5. Decoupling Periodic Zones

If you want to decouple the zones in a periodic pair (also referred to as "deleting" or "slitting" a periodic pair), right-click the periodic zone in the Outline View (under **Setup**/**Boundary Conditions**/**Peri-**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

odic), and select **Delete** in the menu that opens. For conformal pairings, both of the zones in the periodic pair are changed to be of type **symmetry**; for non-conformal pairings, the original face zones remain as type **interface** and the associated mesh interface and periodic zone are deleted.

6.12.6. Slitting Face Zones

The face-zone slitting feature has two uses:

- You can slit a single boundary zone of any double-sided type (that is, any boundary zone that has cells on both sides of it) into two distinct zones.
- You can slit a coupled wall zone into two distinct, uncoupled wall zones.

When you slit a face zone, Fluent will duplicate all faces and nodes, except those nodes that are located at the ends (2D) or edges (3D) of the zone. One set of nodes and faces will belong to one of the resulting boundary zones and the other set will belong to the other zone. The only ill effect of the shared nodes at each end is that you may see some inaccuracies at those points when you graphically display solution data with a slit boundary. (Note that if you adapt the boundary after slitting, you will not be able to fuse the boundaries back together again.)

Before you can slit, you first need to select the zone in the **Boundary Condition** task page and change the **Type** to **wall**. Upon changing the **Type** to **wall**, another shadow zone will be created (that is, if the original zone is called **rad-outlet**, another zone called **rad-outlet-shadow** will be created). Then you can apply the `mesh/modify-zones/slit-face-zone` text command on either of the walls (that is, **rad-outlet** or **rad-outlet-shadow**) to separate them into two distinct walls.

Important:

When a wall and wall-shadow pair is created by slitting a face zone, the wall will inherit the zone id number and face orientation of the original zone. A new zone id number will be created and assigned to the wall-shadow.

For example, the outlet of the radiator in an underhood application is typically of **interior** type (that is, has cells on both sides). If you know the mass flow rate through this zone (either from other CFD models or from test data) and want to apply it as a boundary condition at the radiator outlet, you first need to slit the radiator outlet. To be able to slit it, select **wall** from the **Type** drop-down list in the **Boundary Conditions** task page for this outlet. It will create a wall and a shadow. Then you can use the TUI command (`mesh/modify-zones/slit-face-zone`) to slit them. After it is slit, two additional walls will be created, one facing one side of the outlet and another facing the other. Then you can select the appropriate wall and change the **Type** to **mass-flow-inlet** and specify the mass flow rate using the Mass-Flow Inlet Dialog Box (p. 4966). There is no option of **mass-flow-inlet** without first slitting it.

Important:

You should not confuse “slitting” a face zone with “separating” a face zone. When you slit a face zone, additional faces and nodes are created and placed in a new zone. When you separate a face zone, a new zone will be created, but no new faces or nodes are created; the existing faces and nodes are simply redistributed among the zones.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.12.6.1. Inputs for Slitting Face Zones

If you want to slit a face zone, you can use the `mesh/modify-zones/slit-face-zone` text command.

`mesh` → `modify-zones` → `slit-face-zone`

You will specify the face zone's name or ID, and Fluent will replace the zone with two zones:

```
/mesh/modify-zones > slit-face-zone

 Face zone id/name [] wall-4

   zone 4 deleted
   face zone 4 created
   face zone 10 created
```

Important:

Remember to save a new case file (and a data file, if data exists) after slitting faces.

6.12.7. Orienting Face Zones

The faces of a boundary face zone (which have cells only on one side) are oriented such that the normals are all pointing in one direction. However, for internal face zones (which have cells on both sides), the normals are allowed to point in either direction. To orient them so that they all point in one direction, you can use the following TUI command:

`mesh` → `modify-zones` → `orient-face-zone`

Having all of the normals oriented in one direction is needed for some boundary condition types. For example, the **fan** boundary condition type determines the flow direction based on its normals. If some of the normals are pointing in one direction and some in the other, the correct flow orientation cannot be determined, which leads to incorrect results.

6.12.8. Extruding Face Zones

The ability to extrude a boundary face zone allows you to extend the solution domain without having to exit Fluent. A typical application of the extrusion capability is to extend the solution domain when recirculating flow is impinging on a flow outlet. The current extrusion capability creates prismatic or hexahedral layers based on the shape of the face and normal vectors computed by averaging the face normals to the face zone's nodes. You can define the extrusion process by specifying a list of displacements (in SI units) or by specifying a total distance (in SI units) and parametric coordinates.

Important:

- Note that extrusion is not possible from boundary face zones that have hanging nodes.
- Extruding face zones is not allowed on polygonal face zones.
- Extruding face zones is only allowed in the 3D version of Ansys Fluent.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.12.8.1. Specifying Extrusion by Displacement Distances

You can specify the extrusion by entering a list of displacement distances (in SI units) using the `mesh/modify-zones/extrude-face-zone-delta` text command.

`mesh` → `modify-zones` → `extrude-face-zone-delta`

Note:

This text command is not available in the parallel version of Ansys Fluent.

You will be prompted for the boundary face zone ID or name and a list of displacement distances.

6.12.8.2. Specifying Extrusion by Parametric Coordinates

You can specify the extrusion by specifying a distance (in SI units) and parametric coordinates using the `mesh/modify-zones/extrude-face-zone-para` text command.

`mesh` → `modify-zones` → `extrude-face-zone-para`

Note:

This text command is not available in the parallel version of Ansys Fluent.

You will be prompted for the boundary face zone ID or name, a total distance, and a list of parametric coordinates. The list of parametric coordinates should begin with 0.0 and end with 1.0. For example, the following list of parametric coordinates would create two equally spaced extrusion layers: 0.0, 0.5, 1.0.

6.12.9. Replacing, Deleting, Deactivating, and Activating Zones

Ansys Fluent allows you to append or replace an existing cell zone in the mesh. You can also permanently delete a cell zone and all associated face zones, or temporarily deactivate and activate zones from your Ansys Fluent case.

6.12.9.1. Replacing Zones

This feature allows you to replace a small region of a computational domain with a new region of different mesh quality. This functionality will be required where you may want to make changes to the geometry or mesh quality for any part of the domain. This ability of Ansys Fluent will save you time, since you can modify only the required part of the domain without remeshing the whole domain every time.

The replacement mesh must be prepared in advance, with the following considerations:

- The replacement mesh must contain a single cell zone.
- The cell zone in the replacement mesh must be of the same zone type as the zone that is being replaced.

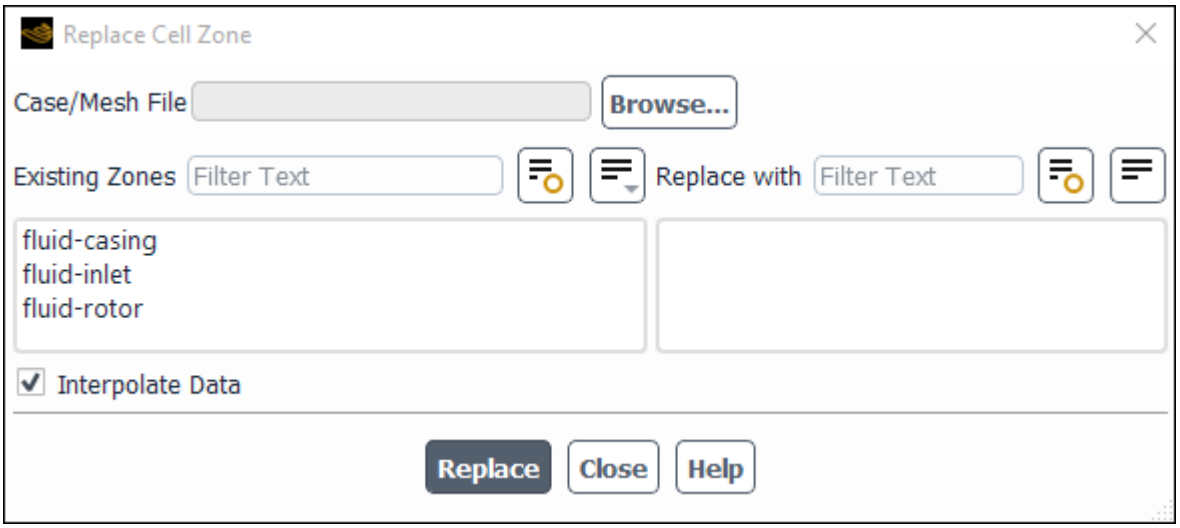
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- If the boundaries of the replacement mesh will form a non-conformal interface with existing zones (that is, zones that are not replaced in the existing mesh), these boundaries should be based on the same geometry as the existing zones. If there are sharp features (for example, 90-degree angles) or curvature in the mesh, it is especially important that both sides of the interface closely follow that feature.
- The replacement cell zone does not need to have the same name as the existing zone being replaced.
- When naming the boundary zones of the replacement cell zone, note that boundary conditions will be automatically transferred from the existing cell zone based on name. All boundaries of the replacement cell zone that have unique names will be assigned the default boundary condition for that zone type.
- When selecting the file with the replacement cell zone, note that legacy mesh files (`.msh`) and legacy case files (`.cas`) may be selected, but default CFF mesh files (`.msh.h5`) and CFF case files (`.cas.h5`) may not.

Replacing a zone is performed using the Replace Cell Zone Dialog Box (p. 5535) (Figure 6.95: The Replace Cell Zone Dialog Box (p. 1253)).

Domain → Zones → Replace Zone...

Figure 6.95: The Replace Cell Zone Dialog Box



To replace a zone, do the following:

1. Click **Browse...** and select the new or modified mesh containing the cell zone that will replace one of the cell zones in the current mesh.

   *The name of the cell zone in the replacement mesh will be displayed in the **Replace with** list.*

2. Under **Existing Zones**, select the zone you want to replace.
3. Under **Replace with**, select the zone from the replacement mesh.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Enable/Disable **Interpolate Data**, if data already exists. If the replacement cell zone is geometrically different, then **Interpolate Data** can be turned off to prevent data interpolation over the non-matching geometries.

   Important:

   Disable **Interpolate Data** if the zone being replaced is part of an overset interface.

5. Click **Replace** to replace the selected zone.

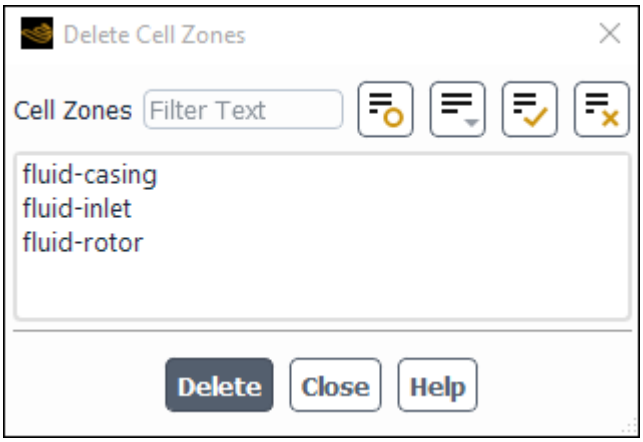
6. Set up the boundary conditions for any of the boundaries of the replacement mesh that do not share a name with one of the existing boundaries.

6.12.9.2. Deleting Zones

To permanently delete zones, select them in the Delete Cell Zones Dialog Box (p. 5378) (Figure 6.96: The Delete Cell Zones Dialog Box (p. 1254)), and click **Delete**.

Domain → Zones → Delete...

Figure 6.96: The Delete Cell Zones Dialog Box



All of the cells, faces, and nodes associated with the cell zone will be deleted. If one of the faces is of type **interior** and borders another cell zone, the face will automatically be changed to a wall and will stay attached to the remaining cell zone.

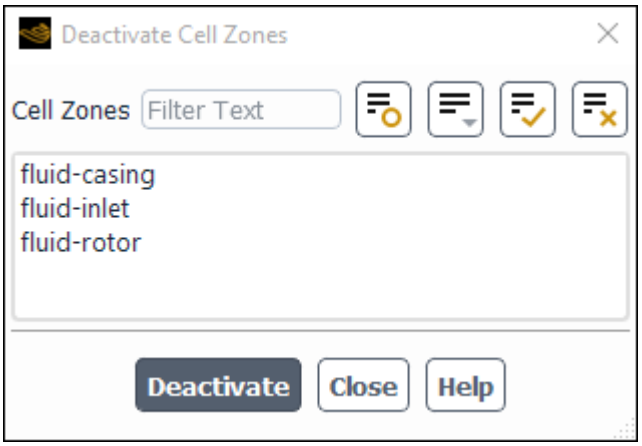
6.12.9.3. Deactivating Zones

To deactivate zones, select them in the Deactivate Cell Zones Dialog Box (p. 5376) (Figure 6.97: The Deactivate Cell Zones Dialog Box (p. 1255)), and click **Deactivate**.

Domain → Zones → Deactivate...

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.97: The Deactivate Cell Zones Dialog Box



Deactivation will separate all relevant interior face zones (that is, fan, interior, porous-jump, or radiator) into wall and wall-shadow pairs.

Note:

When you deactivate a zone using the **Deactivate Cell Zones** dialog box, Ansys Fluent will remove the zone from the mesh and from all relevant solver loops.

Important:

If a cell zone contains mesh interfaces it cannot be deactivated until the solution has been initialized.

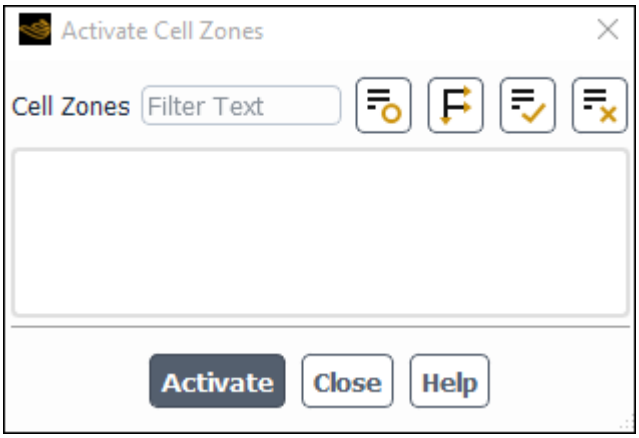
6.12.9.4. Activating Zones

You can reactivate the zones and recover the last data available for them using the Activate Cell Zones Dialog Box (p. 5333) (Figure 6.98: The Activate Cell Zones Dialog Box (p. 1256)).

Domain → **Zones** → **Activate...**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.98: The Activate Cell Zones Dialog Box



Note:

The **Activate Cell Zones** dialog box will only be populated with zones that were previously deactivated.

After reactivation, you need to make sure that the boundary conditions for the wall and wall-shadow pairs are restored correctly to what you assigned before deactivating the zones. If you plan to reactivate them at a later time, make sure that the face zones that are separated during deactivation are not modified. Adaption, however, is supported.

6.12.10. Copying Cell Zones

You can create a copy of a cell zone that is offset from the original either by a translational distance or a rotational angle. Note that in the copied zone, the bounding face zones are all converted to walls, any existing cell data is initialized to a constant value, and non-conformal interfaces and dynamic zones are not copied; otherwise, the model settings are the same as in the original zone.

To copy a zone, use the following text command:

`mesh` → `modify-zones` → `copy-move-cell-zone`

You will then be prompted to enter the ID of the zone you want to copy, and either the distance for translation in each of the axes or the rotational angle, origin, and axis.

Note that if you want the copied zone to be connected to existing zones, you must either fuse the boundaries (as described in Fusing Face Zones (p. 1244)) or set up a non-conformal interface (as described in Using a Non-Conformal Mesh in Ansys Fluent (p. 1164)).

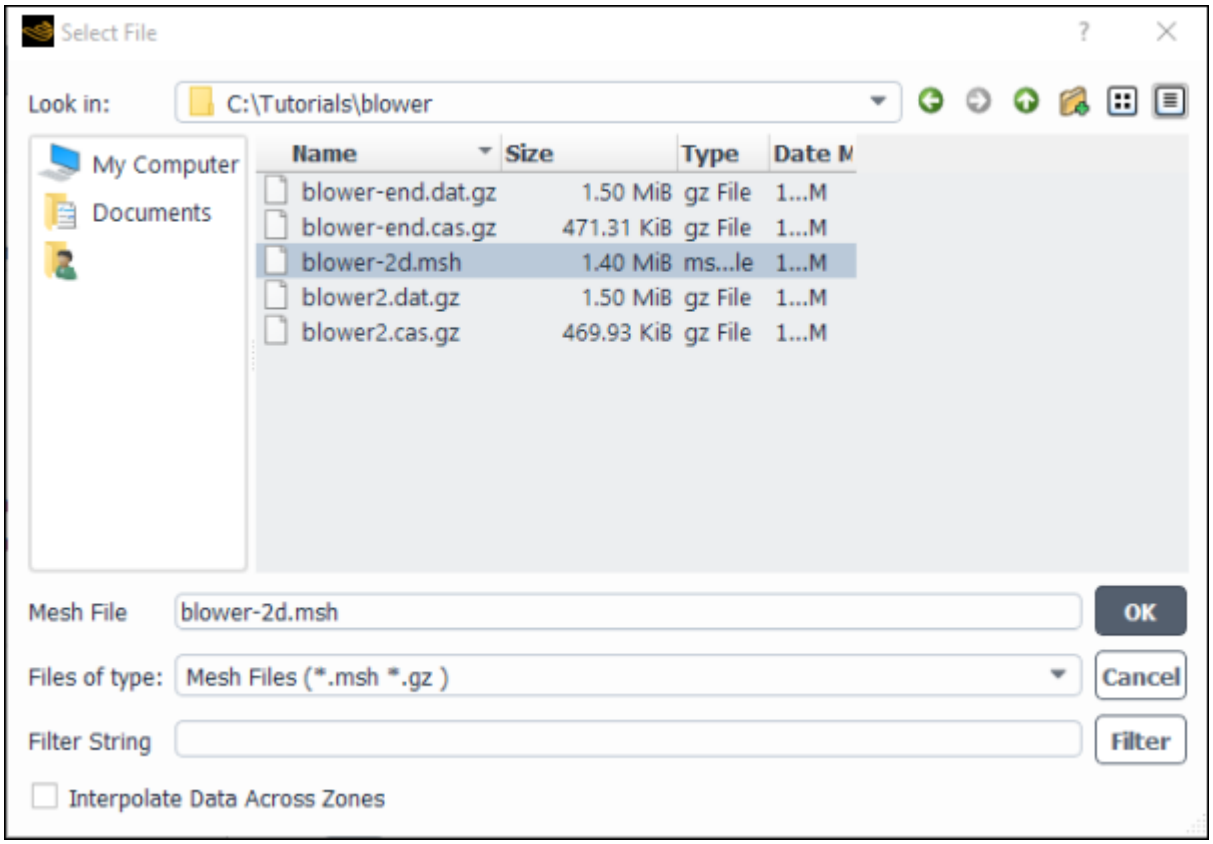
6.12.11. Replacing the Mesh

Ansys Fluent allows you to replace your mesh, so that you can continue to run your simulation on a new mesh without having to manually copy the case file settings or interpolate the existing data. Replacing the mesh globally may be helpful, for example, if you would like to perform a mesh refinement study with a prepared series of meshes, or if your results indicate that your current mesh is not of sufficient quality. Note that the data interpolation is done automatically during the replacement if data exists (that is, you have initialized the flow field or run a calculation).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Global mesh replacement is performed by clicking **Replace Mesh...** in the **Domain** ribbon tab **Zones** group box), which opens the **Select File** dialog box (Figure 6.99: The Select File Dialog Box (p. 1257)).

Figure 6.99: The Select File Dialog Box



6.12.11.1. Inputs for Replacing the Mesh

The steps for replacing the mesh using the **Select File** dialog box (Figure 6.99: The Select File Dialog Box (p. 1257)) are as follows:

1. Select the replacement mesh from the appropriate folder.

2. By default, data is interpolated between matching zone pairs (that is, between the zones with the same names in both the current mesh and the replacement mesh). You can enable the **Interpolate Data Across Zones** option if you want to interpolate data across cell zones when replacing the mesh. This option is appropriate when the matching zone pairs do not have the same interior zone boundaries. Note that global conservation of data is not enforced when the **Interpolate Data Across Zones** option is enabled, so it should only be used when absolutely necessary. For best data interpolation, the zone boundaries of the replacement mesh should be coincident with those of the current mesh.

   When running in parallel the replacement mesh gets partitioned such that matching cells reside on the same compute node. In some cases, differences in mesh resolution can cause the mesh to not be able to find its interpolation cell on the same compute node during interpolation. Fluent then automatically enables **Interpolate Data Across Zones** to ensure successful data interpolation across zones, even if you have not enabled the option. To avoid this behavior use the Scheme command: `(rpsetvar 'dynamesh/replace-mesh/partition-per-zone?`

`#t`). Note that using this command comes at the expense of requiring additional repartitioning steps.

3. Click the **OK** button to replace the mesh.

6.12.11.2. Limitations

The following limitations apply when replacing meshes:

- The boundary conditions of the zones in the current mesh are mapped onto the zones with the same names in the replacement mesh, as described in Reading and Writing Boundary Conditions (p. 946). If your replacement mesh contains zones for which no match is found, these zones will have the default boundary conditions for that zone type.
- The replacement mesh is expected to be an Ansys Fluent mesh file in the legacy format (`.msh`). You may select an Ansys Fluent legacy case file instead, but be aware that only the mesh information will be used and all of the setup information associated with that case file will be ignored. The default CFF files (`.msh.h5` or `.cas.h5`) may not be used as a replacement mesh.
- If you intend to select an Ansys Fluent legacy case file (`.cas`) as the replacement mesh, you must first delete any defined non-conformal mesh interfaces in the case file (as described in Using a Non-Conformal Mesh in Ansys Fluent (p. 1164)).
- You should ensure that the replacement mesh has the same mesh scaling as your current mesh. The data interpolation will not work properly if the meshes are scaled differently.

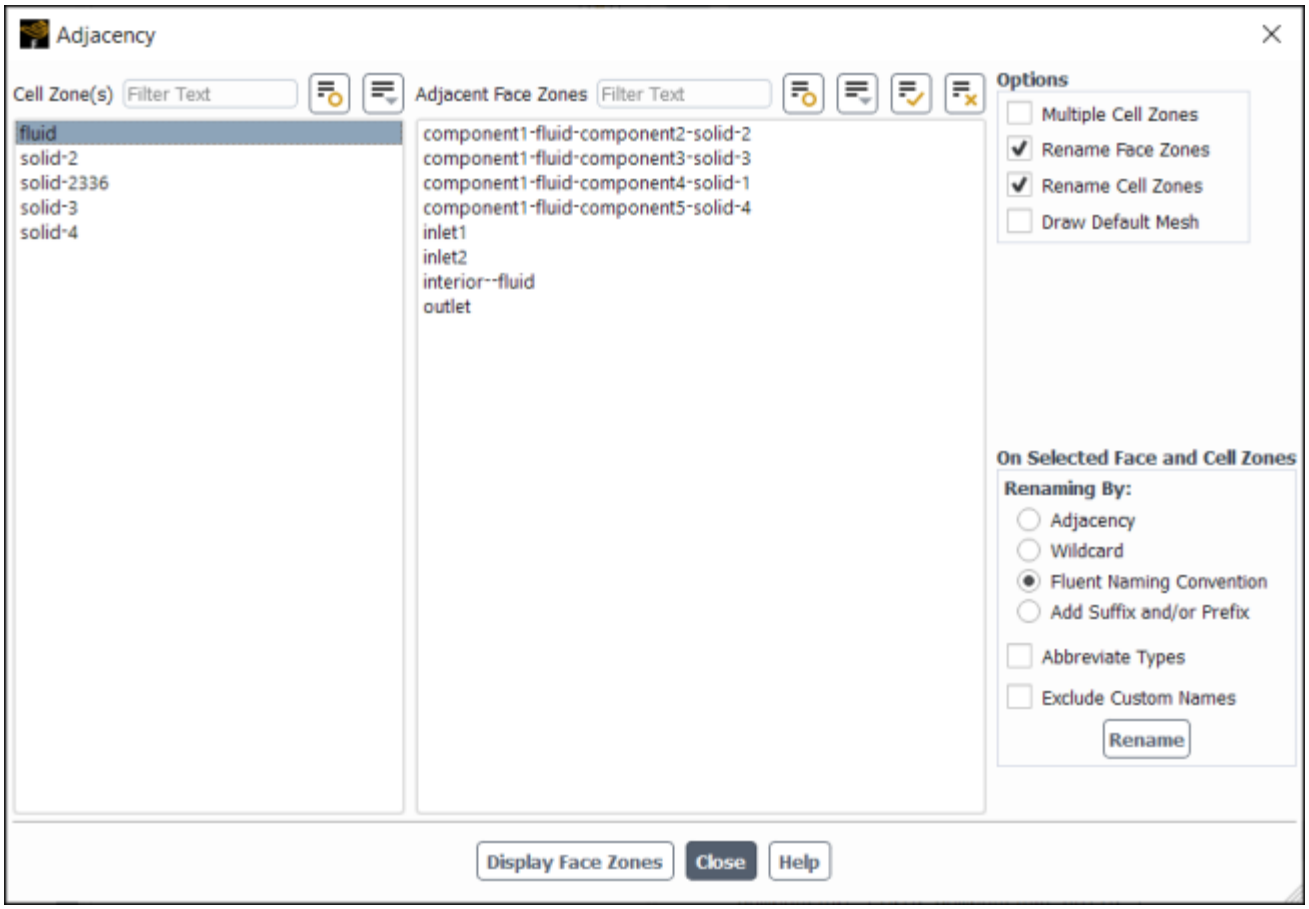
6.12.12. Managing Adjacent Zones

In some cases you may want to identify and display the face zones which are adjacent to a cell zone. You can do this using the **Adjacency** dialog box.

Domain → **Zones** → **Adjacency...**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.100: The Adjacency Dialog Box



Using the **Adjacency** dialog box (Figure 6.100: The Adjacency Dialog Box (p. 1259)) you can also optionally rename zones based on their adjacency or with default names based on zone type. The steps to use the **Adjacency** dialog box are:

1. Open the **Adjacency** dialog box by clicking **Adjacency...** in the **Domain** ribbon tab (**Zones** group box).

2. Select a zone under **Cell Zone(s)** to populate the **Adjacent Face Zones** list. You can use the 'Toggle Tree View' icon ( ) to group the cell zones by type. If the **Multiple Cell Zones** option is disabled, only one cell zone can be selected at a time.

3. Select the face zones you want to display in **Adjacent Face Zones** and click the **Display Face Zones** button.

4. Enable **Draw Default Mesh** to open the **Mesh Display** dialog box where you may choose to display mesh zones. These will be displayed permanently while others will be displayed as currently selected in the **Adjacent Face Zones** list. This is useful for finding your way through a new and complex mesh.

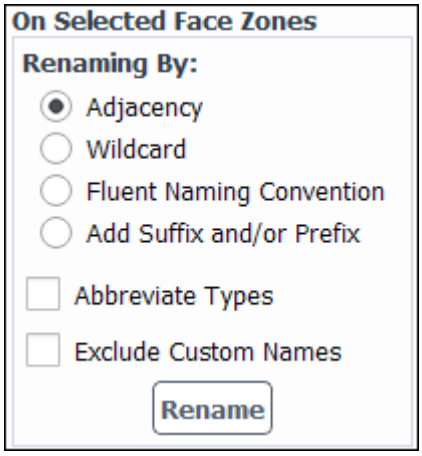
5. Enable **Rename Face Zones** if you want to rename or clean up some of the names that may cause confusion. See Renaming Zones Using the Adjacency Dialog Box (p. 1260) for more information.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.12.12.1. Renaming Zones Using the Adjacency Dialog Box

You can rename selected cell zones and/or face zones from the Adjacency dialog box after enabling **Rename Face Zones** and/or **Rename Cell Zones**. The following renaming methods are available:

Rename by Adjacency

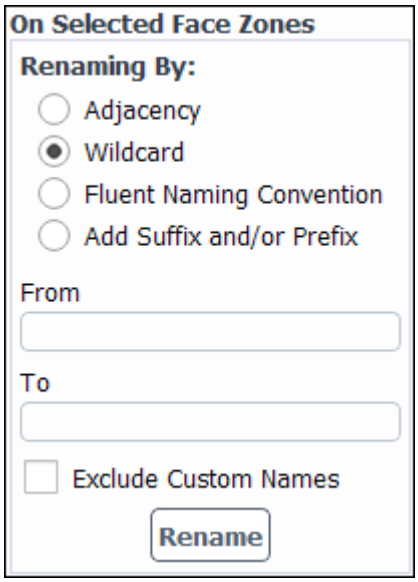


appends the name of the adjacent cell zone to the selected face zone(s). For example, if **fluid** is selected in the **Cell Zone(s)** and **interior** is selected in the **Adjacent Face Zones** list, then renaming by adjacency produces **interior-fluid**. If the name is already in use, the original zone ID is appended in addition in order to create a unique name. Note that it is best if you avoid using long cell zone names.

Note:

Renaming by adjacency is only available for face zones and is not available for renaming cell zones.

Rename by Wildcard



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

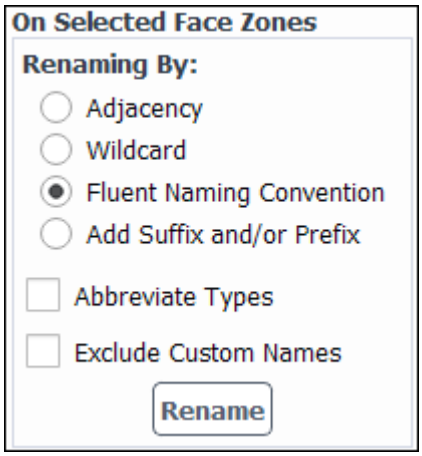
performs pattern matching of the selected zone names against the pattern in the **From** text box (with optional wildcards) and replaces a matching substring with the literal string in the **To** text box. Wildcard characters * and ? are interpreted as follows:

- A * at the beginning and/or end of the **From** pattern matches zero or more characters at the beginning and/or end of the zone name that are retained during renaming with the rest of the name replaced by the **To** string.

  A * used anywhere except at the beginning or end of the **From** pattern is not supported and may have unpredictable results.

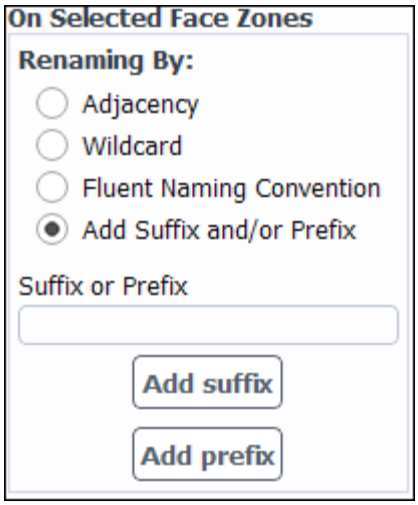
- A ? matches exactly one character and is considered part of the string to be replaced. Multiple ? characters can be used to match substrings of more than one character.

Fluent Naming Convention



renames the selected surface to be a combination of the surface type and the surface ID. In the case of cell zones, the zone is renamed to be a combination of the zone type and zone ID.

Add Suffix and/or Prefix



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

adds the provided text in the **Suffix or Prefix** field to either the beginning or end of the selected surface(s) name(s) or cell zone names. Click **Add Suffix** to add the provided text at the end of the name and click **Add Prefix** to add the provided text at the beginning of the name.

There are two additional options available for some renaming techniques:

- **Exclude Custom Names**—excludes customized names (those that do not conform to a recognized pattern or match any default names) from renaming. This is a protective measure so as not to accidentally destroy your desired naming. Disabling this option will unconditionally rename all selected zones according to the specified renaming method and customized names will be permanently lost.
- **Abbreviate Types**—abbreviates the zone type (for example, `vi` for velocity inlet, `int` for interior, `ifc` for interface, and so on).

6.12.13. Reordering the Domain

In a Fluent session that uses multiple processes, the mesh domain is automatically reordered when it is read, in order to increase memory access efficiency. The reordering uses the Reverse Cuthill-McKee algorithm [33] (p. 5656), and is applied to cells and faces.

A typical output produced during the domain reordering at read is shown below:

```
Building...
     mesh
 auto partitioning mesh by Metis (fast),
 distributing mesh
  parts...,
  faces...,
  nodes...,
  cells...,
        bandwidth reduction using Reverse Cuthill-McKee: 3875/150 = 25.8333
```

The bandwidth is the maximum difference between neighboring cells in the zone—that is, if you numbered each cell in the zone list sequentially and compared the differences between these indices.

6.12.14. Scaling the Mesh

Internally, Ansys Fluent stores the computational mesh in meters, the SI unit of length. When mesh information is read, it is assumed that the mesh was generated in units of meters. If your mesh was created using a different unit of length (inches, feet, centimeters, and so on), you must scale the mesh to meters. To do this, you can select from a list of common units to convert the mesh or you can supply your own custom scale factors. Each node coordinate will be multiplied by the corresponding scale factor.

Scaling can also be used to change the physical size of the mesh. For instance, you could stretch the mesh in the x direction by assigning a scale factor of 2 in the x direction and 1 in the y and z direc-

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

tions. This would double the extent of the mesh in the x direction. However, you should use anisotropic scaling with caution, since it will change the aspect ratios of the cells in your mesh.

Important:

- If you plan to scale the mesh in any way, you should do so before you compute the view factors (as part of an S2S radiation problem), initialize the flow, or begin calculations. Any data that exists when you scale the mesh will be invalid.
- It is a good practice to scale the mesh before setting up the case, especially when you plan to create mesh interfaces or shell conduction zones.
- Scaling the mesh makes the graphics window **[Out of Date]**. Right-click in the graphics window and select **Refresh Display** to update the window.

  You may have to click *to see the object in the graphics window after refreshing the display.*

  For the refresh of a mesh display, Fluent displays the surfaces that are currently selected in the global ***Mesh Display*** *dialog box (accessed by clicking* *in the toolbar). In some instances this may result in the refreshed display not matching what was originally displayed.*

You have the option of scaling the entire mesh, or individual cell zones. For details, see the following:

6.12.14.1. Scaling the Entire Mesh

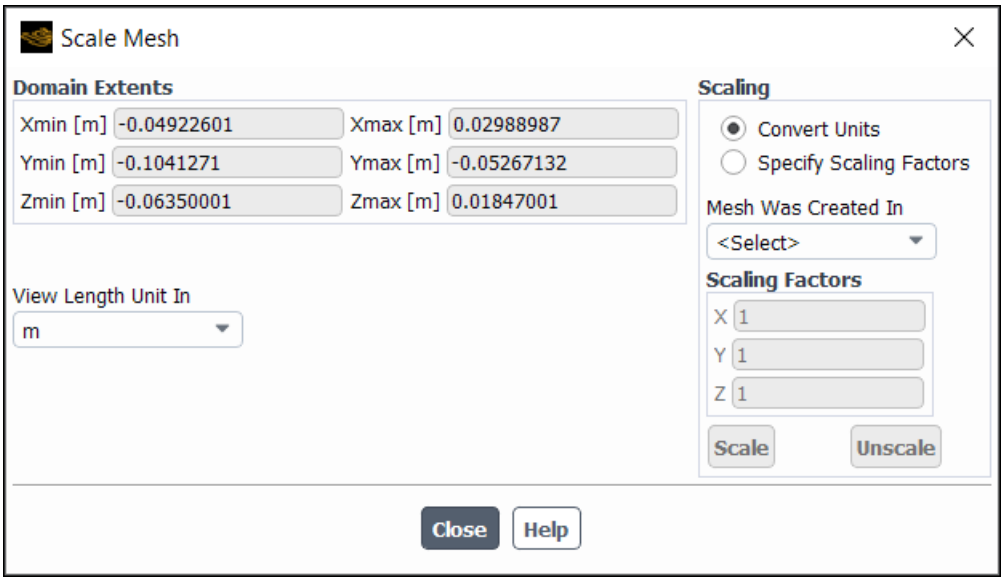
6.12.14.2. Scaling Individual Cell Zones

6.12.14.1. Scaling the Entire Mesh

You will use the Scale Mesh Dialog Box (p. 4634) (Figure 6.101: The Scale Mesh Dialog Box (p. 1264)) to scale the entire mesh, either to change the unit of measurement or to apply custom scaling factors.

Setup → **General** → **Mesh** → **Scale...**

Figure 6.101: The Scale Mesh Dialog Box



The procedure for scaling the mesh is as follows:

1. Use the conversion factors provided by Ansys Fluent by selecting **Convert Units** in the **Scaling** group box. Then indicate the units used when creating the mesh by selecting the appropriate abbreviation for meters, centimeters, millimeters, inches, or feet from the **Mesh Was Created In** drop-down list. The **Scaling Factors** will automatically be set to the correct values (for example, 0.0254 meters/inch).

   If you created your mesh using units other than those in the **Mesh Was Created In** drop-down list, you can select **Specify Scaling Factors** and enter values for **X**, **Y**, and **Z** manually in the **Scaling Factors** group box (for example, the number of meters per yard).

2. Click the **Scale** button. The **Domain Extents** will be updated to show the correct range in meters. If you prefer to use your original unit of length during the Ansys Fluent session, you can follow the procedure described below to change the unit.

6.12.14.1.1. Changing the Unit of Length

As mentioned in Step 2. of the previous section, when you scale the mesh you do not change the units; you just convert the original dimensions of your mesh points from your original units to meters by multiplying each node coordinate by the specified **Scaling Factors**. If you want to work in your original units, instead of in meters, you can make a selection from the **View Length Unit In** drop-down list. This updates the **Domain Extents** to show the range in your original units and automatically changes the length unit in the Set Units Dialog Box (p. 4641) (see Customizing Units (p. 1011)). Note that this unit will be used for all future inputs of length quantities.

6.12.14.1.2. Unscaling the Mesh

If you use the wrong scale factor, accidentally click the **Scale** button twice, or want to undo the scaling for any other reason, you can click the **Unscale** button. "Unscaling" simply divides each of the node coordinates by the specified **Scale Factors**. (Selecting **m** in the **Mesh Was Created In** list and clicking on **Scale** will *not* unscale the mesh.)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6.12.14.1.3. Changing the Physical Size of the Mesh

You can also use the Scale Mesh Dialog Box (p. 4634) to change the physical size of the mesh. For example, if your 2D mesh is 5 feet by 8 feet, and you want to model the same geometry with dimensions twice as big (10 feet by 16 feet), you can enter 2 for **X** and **Y** in the **Scaling Factors** group box and click **Scale**. The **Domain Extents** will be updated to show the new range.

6.12.14.2. Scaling Individual Cell Zones

You have the ability to scale one or more individual cell zones. This could be useful, for example, if you append a case file to a mesh that is of a different scale. To scale zones, use the following text command:

`mesh` → `modify-zones` → `scale-zone`

You will be prompted to specify one or more cell zones, as well as the scaling factors in the coordinate directions.

Note:

You cannot scale a zone that is conformally connected to a zone that is not being scaled.

6.12.15. Translating the Mesh

You can "move" the mesh by applying prescribed offsets to the Cartesian coordinates of all the nodes in the mesh. This would be necessary for a rotating problem if the mesh were set up with the axis of rotation not passing through the origin, or for an axisymmetric problem if the mesh were set up with the axis of rotation not coinciding with the x axis. It is also useful if, for example, you want to move the origin to a particular point on an object (such as the leading edge of a flat plate) to make an XY plot have the desired distances on the x axis.

You have the option of translating the entire mesh, or individual cell zones. For details, see the following:

6.12.15.1. Translating the Entire Mesh

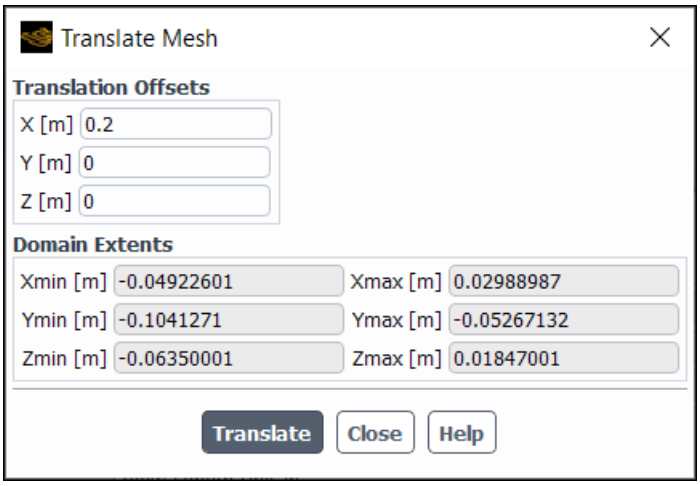
6.12.15.2. Translating Individual Cell Zones

6.12.15.1. Translating the Entire Mesh

You can translate the entire mesh using the Translate Mesh Dialog Box (p. 5576) (Figure 6.102: The Translate Mesh Dialog Box (p. 1266)).

Domain → **Mesh** → **Transform** → **Translate...**

Figure 6.102: The Translate Mesh Dialog Box



The procedure for translating the mesh is as follows:

1. Enter the desired translations in the x, y, and (for 3D) z directions (that is, the desired delta in the axes) in the **X**, **Y**, and **Z** text-entry boxes in the **Translation Offsets** group box. You can specify positive or negative real numbers in the current unit of length.

2. Click the **Translate** button and redisplay the mesh. The **Domain Extents** will be updated to display the new extents of the translated mesh. (Note that the **Domain Extents** are purely informational; you cannot edit them manually.)

6.12.15.2. Translating Individual Cell Zones

You have the ability to translate one or more individual cell zones. This could be useful, for example, if you append a case file to a mesh and they are not properly located relative to each other. To translate zones, use the following text command:

`mesh` → `modify-zones` → `translate-zone`

You will be prompted to specify one or more cell zones, as well as the offsets in the coordinate directions.

Note:

You cannot translate a zone that is conformally connected to a zone that is not being translated.

6.12.16. Rotating the Mesh

The ability to rotate the mesh is analogous to the ability to translate the mesh in Ansys Fluent. You can rotate the mesh about the x, y, or (for 3D) z axis and also specify the rotation origin. This option is useful in the cases where the structural mesh and the CFD mesh are offset by a small angle.

You have the option of rotating the entire mesh, or individual cell zones. For details, see the following:

6.12.16.1. Rotating the Entire Mesh

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

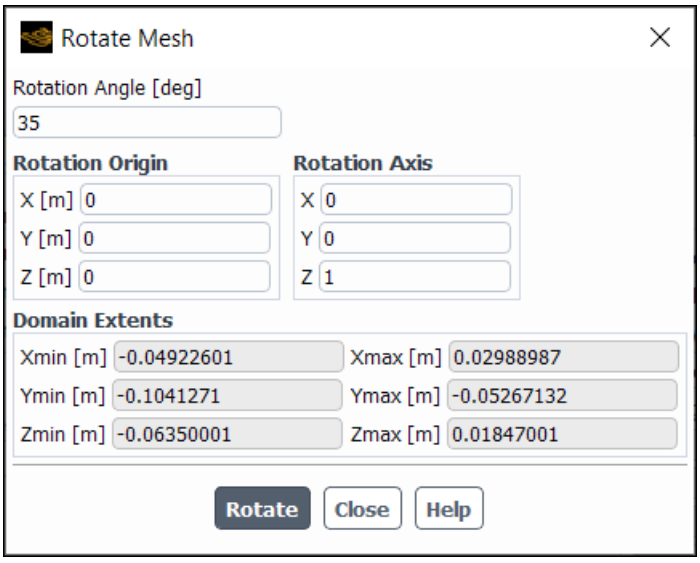
6.12.16.2. Rotating Individual Cell Zones

6.12.16.1. Rotating the Entire Mesh

You can rotate the entire mesh using the Rotate Mesh Dialog Box (p. 5544) (Figure 6.103: The Rotate Mesh Dialog Box (p. 1267)).

Domain → Mesh → Transform → Rotate...

Figure 6.103: The Rotate Mesh Dialog Box



The procedure for rotating the mesh is as follows:

1. Specify the required **Rotation Angle** for the mesh. You can specify any positive or negative real number in the correct unit of angle.

2. In the **Rotation Origin** group box, enter **X**, **Y**, and (for 3D) **Z** coordinates to specify a new origin for the axis of rotation.

3. In the **Rotation Axis** group box, enter values for the **X**, **Y**, and (for 3D) **Z** axes to specify the vector for the axis of rotation.

4. Click the **Rotate** button and redisplay the mesh.

   The Domain Extents will be updated to display the new extents of the rotated mesh. (Note that the Domain Extents are purely informational; you cannot edit them manually.)

6.12.16.2. Rotating Individual Cell Zones

You have the ability to rotate one or more individual cell zones. This could be useful, for example, if you append a case file to a mesh and they are not properly oriented relative to each other. To rotate zones, use the following text command:

`mesh → modify-zones → rotate-zone`

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You will be prompted to specify one or more cell zones, as well as the rotation angle, origin, and axis components.

Note:

You cannot rotate a zone that is conformally connected to a zone that is not being rotated.

6.12.17. Improving the Mesh by Smoothing and Swapping

Smoothing and face swapping are tools that complement mesh adaption by increasing the quality of the final numerical mesh. Smoothing repositions the nodes, and face swapping modifies the cell connectivity to achieve these improvements in quality.

Important:

Only smoothing that is based on quality is recommended; face swapping and smoothing based on skewness or a Laplacian operator have more limitations, and support for them may be removed in a future release.

Important:

Face swapping is applicable only to meshes with triangular or tetrahedral cells.

Important:

Face swapping and smoothing based on skewness or a Laplacian operator are available only for serial cases; only quality-based smoothing can be used for parallel cases.

For additional information, see the following sections:

6.12.17.1. Smoothing

6.12.17.2. Face Swapping

6.12.17.3. Combining Skewness-Based Smoothing and Face Swapping

6.12.17.1. Smoothing

The three smoothing methods that are available in Ansys Fluent are:

- quality-based smoothing

  This method is the only recommended method, and is available for all types of meshes in serial and parallel.

- Laplacian smoothing

  This method is not recommended, though it is available for all types of meshes in serial (and is best suited for quadrilateral and hexahedral meshes).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- skewness-based smoothing

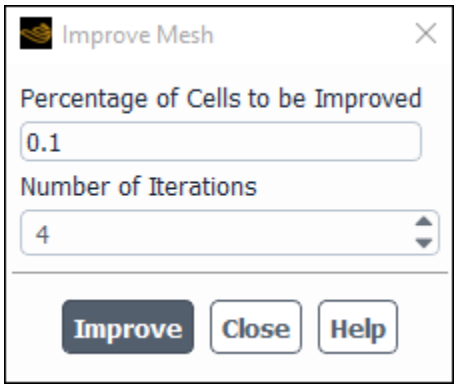
  This method is not recommended, though it is available for triangular and tetrahedral meshes in serial; it can be used alternatively with face swapping (see Combining Skewness-Based Smoothing and Face Swapping (p. 1274)).

6.12.17.1.1. Quality-Based Smoothing

Smoothing that is based on quality is performed using the Improve Mesh Dialog Box (p. 5439) (Figure 6.104: The Improve Mesh Dialog Box (p. 1269)).

Domain → Mesh → Quality → Improve Mesh Quality...

Figure 6.104: The Improve Mesh Dialog Box



Ansys Fluent divides the mesh into a number of "bins", each of which contain a certain number of cells. Improvements are attempted on the cells in those bins that exhibit the lowest orthogonal quality (as defined in Mesh Quality (p. 1120)). As part of this method, you specify the percentage of the total number of cells, in order to determine how many bins are modified.

Note that this smoothing is similar to when you use the `mesh/repair-improve/improve` text command. The advantage of using the **Improve Mesh** dialog box rather than the text command is that you can control the percentage of the cells that Ansys Fluent attempts to improve.

To perform quality-based smoothing, do the following steps:

1. In the Improve Mesh Dialog Box (p. 5439) (Figure 6.104: The Improve Mesh Dialog Box (p. 1269)), enter the **Percentage of Cells to be Improved**.

   Important:

   Quality-based smoothing will be CPU intensive if you specify a large value for the **Percentage of Cells to be Improved**. It is recommended that you enter a small value initially, and then perform the smoothing process multiple times, if necessary. Note that the maximum percentage allowed is 10%.

2. Specify the number of successive smoothing sweeps to be performed on the mesh in the **Number of Iterations** number-entry box. The default value is 4.

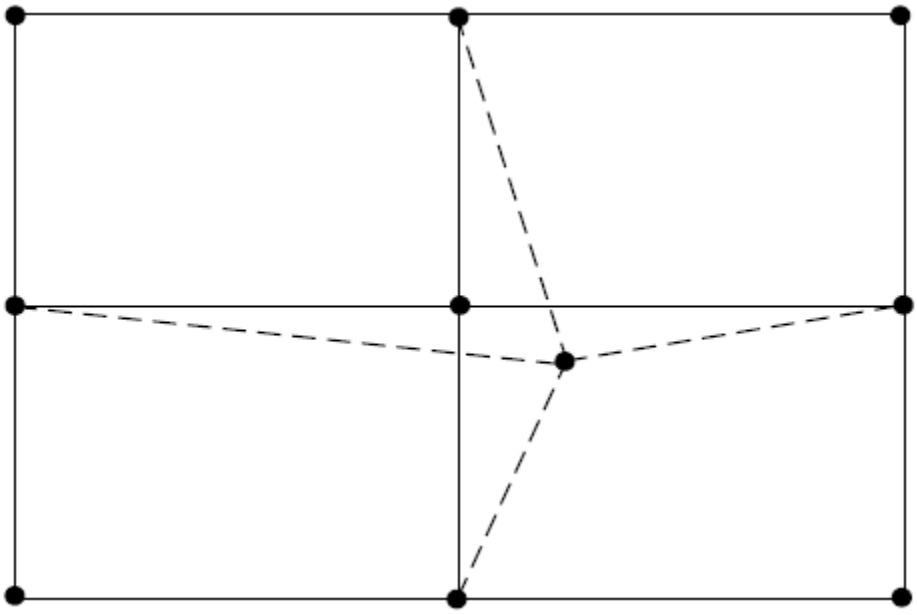
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Click the **Improve** button.

6.12.17.1.2. Laplacian Smoothing

When you use this method, a Laplacian smoothing operator is applied to the unstructured mesh to reposition nodes. The new node position is the average of the positions of its node neighbors. The computed node position increment is multiplied by the relaxation factor (which is set to a value between 0.0 and 1.0). A value of zero for the relaxation factor results in no movement of the node, and a value of unity results in movement equivalent to the entire computed increment. Figure 6.105: Result of Smoothing Operator on Node Position (p. 1270) illustrates the new node position for a typical configuration of quadrilateral cells. The dashed line is the original mesh and the solid line is the final mesh.

Figure 6.105: Result of Smoothing Operator on Node Position



This repositioning strategy improves the skewness of the mesh, but relaxes the clustering of node points. In extreme circumstances, the present operator may create mesh lines that cross over the boundary, creating negative cell volumes. This is most likely to occur near sharp or coarsely resolved convex corners, especially if you perform multiple smoothing operations with a large relaxation factor. Figure 6.106: Initial Mesh Before Smoothing Operation (p. 1271) illustrates an initial tetrahedral mesh before one unrelaxed smoothing iteration creates mesh lines that cross over each other (Figure 6.107: Mesh Smoothing Causing Mesh-Line Crossing (p. 1271)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 6.106: Initial Mesh Before Smoothing Operation

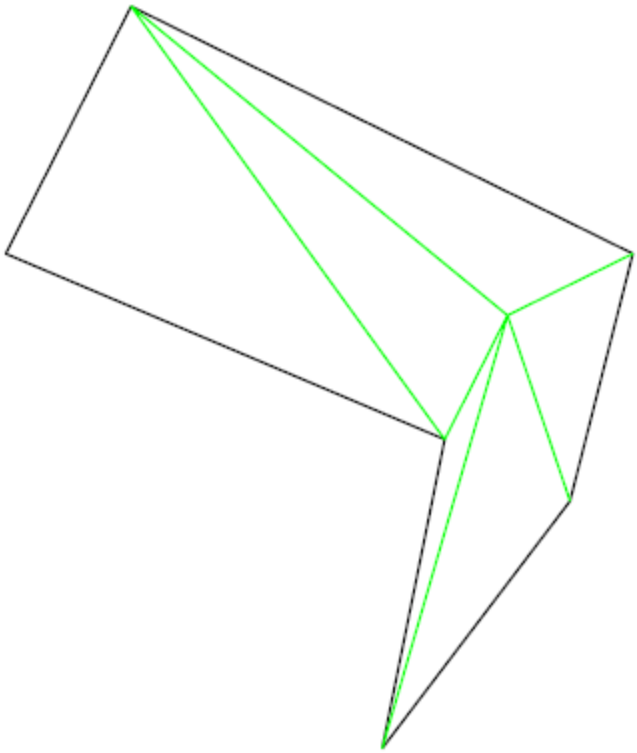


Figure 6.107: Mesh Smoothing Causing Mesh-Line Crossing

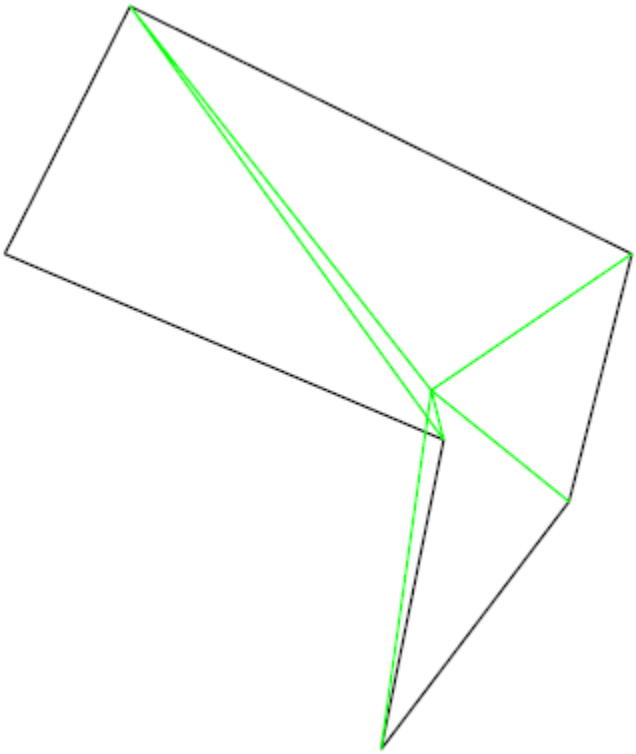

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The default smoothing parameters are designed to improve mesh quality with minimal adverse effects, but it is recommended that you save a case file before smoothing the mesh. If you apply a conservative relaxation factor and start with a good quality initial mesh, the frequency of failure due to smoothing is extremely low in two dimensions. However, corruption of the mesh topology occurs much more frequently in three dimensions, particularly with tetrahedral meshes.

The smoothing operator can also be applied repeatedly, but as the number of smoothing sweeps increase, the node points have a tendency to pull away from boundaries and the mesh tends to lose any clustering characteristics.

To perform Laplacian smoothing, enter the `mesh/smooth-mesh` text command in the console and respond to the prompts as follows:

1. Enter `"laplace"` for the `type of smoothing`.
2. Specify the number of successive smoothing sweeps to be performed on the mesh in response to the `number of iterations` prompt. The default value is 4.
3. Specify the factor by which to multiply the computed position increment for the node in response to the `relaxation factor` prompt. The lower the factor, the more reduction in node movement.

6.12.17.1.3. Skewness-Based Smoothing

When you use skewness-based smoothing, Ansys Fluent applies a smoothing operator to the mesh, repositioning interior nodes to lower the maximum skewness of the mesh. Ansys Fluent will try to move interior nodes to improve the skewness of cells with skewness greater than the specified "skewness threshold". This process can be very time consuming, so perform smoothing only on cells with high skewness.

Improved results can be obtained by smoothing the nodes several times. There are internal checks that will prevent a node from being moved if moving it causes the maximum skewness to increase, but it is common for the skewness of some cells to increase when a cell with a higher skewness is being improved. Thus, you may see the average skewness increase while the maximum skewness is decreasing.

Important:

Carefully consider whether the improvements to the mesh due to a decrease in the maximum skewness are worth the potential increase in the average skewness. Performing smoothing only on cells with very high skewness (for example, 0.8 or 0.9) may reduce the adverse effects on the average skewness.

To perform skewness-based smoothing, enter the `mesh/smooth-mesh` text command in the console and respond to the prompts as follows:

1. Enter `"skewness"` for the `type of smoothing`.
2. Specify the number of successive smoothing sweeps to be performed on the mesh in response to the `number of iterations` prompt. The default value is 4.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Specify the minimum cell skewness value for which node smoothing will be attempted in response to the `skewness threshold` prompt. Ansys Fluent will try to move interior nodes to improve the skewness of cells with skewness greater than this value. By default, skewness threshold is set to 0.4 for 2D cases and 0.8 for 3D cases.

6.12.17.2. Face Swapping

While it is not recommended over smoothing (and support for it may be removed in future releases), face swapping can be used to improve the quality of a triangular or tetrahedral mesh in the serial version of Ansys Fluent.

To perform face swapping, enter the `mesh/swap-mesh-faces` text command repeatedly until the console report declares that 0 faces were swapped out. The console report will display the total number of faces that were visited and tested for possible face swapping.

6.12.17.2.1. Triangular Meshes

The approach for triangular meshes is to use the Delaunay circle test to decide if a face shared by two triangular cells should be swapped. A pair of cells sharing a face satisfies the circle test if the circumcircle of one cell does not contain the unshared node of the second cell. Figure 6.108: Examples of Cell Configurations in the Circle Test (p. 1273) illustrates cell neighbors in the circle test. In cases where the circle test is not satisfied, the diagonal or face is swapped, as illustrated in Figure 6.109: Swapped Faces to Satisfy the Delaunay Circle Test (p. 1273).

Figure 6.108: Examples of Cell Configurations in the Circle Test

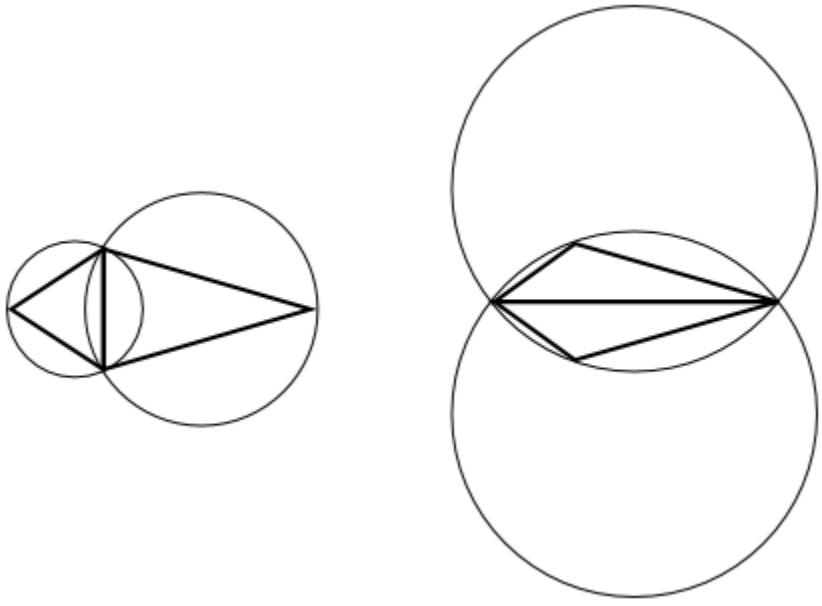

Figure 6.109: Swapped Faces to Satisfy the Delaunay Circle Test

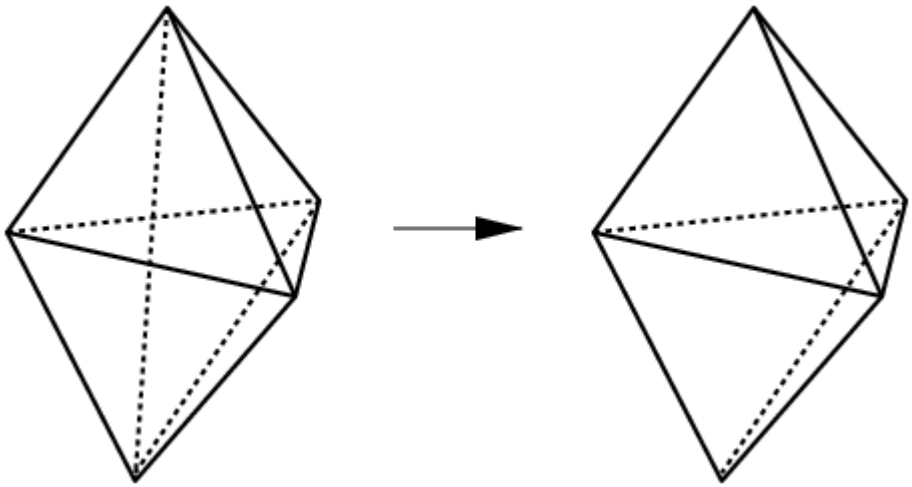
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Repeated application of the face-swapping technique will produce a constrained Delaunay mesh. If you have a Delaunay mesh, it is a unique triangulation that maximizes the minimum angles in the mesh. Thus, the triangulation tends toward equilateral cells, providing the most equilateral mesh for the given node distribution. For more information on Delaunay mesh generation, see Generating Tetrahedral Meshes (p. 758) in the Fluent Meshing section of the User's Guide.

6.12.17.2.2. Tetrahedral Meshes

For tetrahedral meshes, face swapping consists of searching for configurations of three cells sharing an edge and converting them into two cells sharing a face to decrease skewness and the cell count (see Figure 6.110: 3D Face Swapping (p. 1274)).

Figure 6.110: 3D Face Swapping



6.12.17.3. Combining Skewness-Based Smoothing and Face Swapping

As mentioned in Skewness-Based Smoothing (p. 1272), skewness-based smoothing should usually be alternated with face swapping. Guidelines for this procedure are presented here.

- Perform four smoothing iterations using a `skewness threshold` of 0.8 for 3D cases, or 0.4 for 2D cases.
- Swap until the number of faces swapped decreases to 0.
- For 3D meshes, decrease the `skewness threshold` to 0.6 and repeat the smoothing/swapping procedure.

6.12.18. Boundary Layer Redistribution

After performing mesh operations, the boundary layer zone may not satisfy the original growth rate. When the boundary layer is composed of hex and/or wedge cells, you can restore the desired growth rate by using the `mesh/redistribute-boundary-layer` text command. You will be prompted to enter a face zone and the desired growth rate. The face zone you specify must be adjacent to the boundary layer zone that you want to redistribute.

```
>  mesh redistribute-boundary-layer
face zone id/name [] wall-fluid
growth rate [1.1] 1.2
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Fluent will redistribute the nodes in a boundary region that extends into the mesh from the face zone you specify until one of the following criteria is encountered:

- the edge of the domain
- a change in zone
- a change in element type

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

of ANSYS, Inc. and its subsidiaries and affiliates.

Chapter 7: Cell Zone and Boundary Conditions

This chapter describes the cell zone and boundary condition options available in Ansys Fluent. Details regarding the cell zone and boundary condition inputs and the internal treatment at boundaries are provided.

The information in this chapter is divided into the following sections:

7.1. Overview
7.2. Cell Zone Conditions
7.3. Operating Conditions
7.4. Boundary Conditions
7.5. Editing Multiple Boundary Conditions at Once
7.6. Transient Cell Zone and Boundary Conditions
7.7. Boundary Acoustic Wave Models
7.8. User-Defined Fan Model
7.9. Profiles
7.10. Coupling Boundary Conditions with GT-POWER
7.11. Coupling Boundary Conditions with WAVE

7.1. Overview

Cell zone and boundary conditions specify the flow and thermal variables on the boundaries of your physical model. They are, therefore, a critical component of your Ansys Fluent simulations and it is important that they are specified appropriately.

In this chapter, most of the cell zones and boundary conditions will be described in detail, and an explanation of how to set them and where they are most appropriately used will be provided.

7.1.1. Available Cell Zone and Boundary Types
7.1.2. The Cell Zone and Boundary Conditions Task Pages
7.1.3. Changing Cell and Boundary Zone Types
7.1.4. Setting Cell Zone and Boundary Conditions
7.1.5. Copying Cell Zone and Boundary Conditions
7.1.6. Exporting Boundary Zones in CSV Format
7.1.7. Changing Cell or Boundary Zone Names
7.1.8. Defining Non-Uniform Cell Zone and Boundary Conditions
7.1.9. Defining and Viewing Parameters
7.1.10. Selecting Cell or Boundary Zones in the Graphics Display
7.1.11. Operating and Periodic Conditions

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.1.12. Saving and Reusing Cell Zone and Boundary Conditions

7.1.1. Available Cell Zone and Boundary Types

The cell zone and boundary zone types available in Ansys Fluent are classified as follows:

Table 7.1: Zone Types by Category

Category	Zone Types
External	axis, degassing, exhaust fan, inlet vent, intake fan, interface, mass-flow inlet, mass-flow outlet, outflow, outlet vent, overset, pressure far-field, pressure inlet, pressure outlet, symmetry, velocity inlet, and wall (one-sided only)
Internal	fan, interior, porous jump, radiator, RANS/LES interface, and wall (two-sided only)
Periodic	periodic
Cells	fluid, solid (porous media and 3D fans are a type of fluid cell)

Note that internal boundary zones are connected with the cells on both sides, whereas external boundary zones are connected with the cells on only one side.

7.1.2. The Cell Zone and Boundary Conditions Task Pages

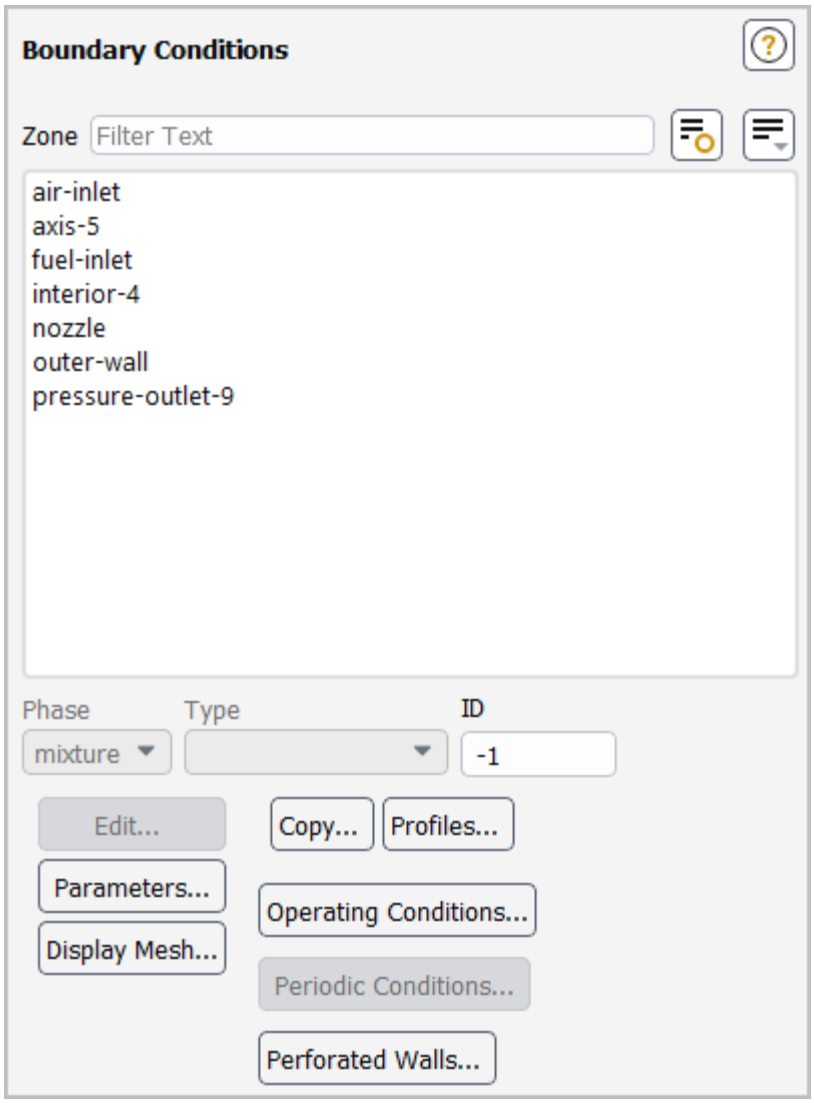
The **Cell Zone Conditions** and **Boundary Conditions** task pages (Figure 7.1: The Boundary Conditions Task Page (p. 1279)) display lists of the zones (which can be grouped by name or zone type), and allow you to revise their settings and perform other related actions. They provide an alternate setup method to working directly in the Outline View tree.

Setup → **Cell Zone Conditions**

Setup → **Boundary Conditions**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.1: The Boundary Conditions Task Page



The sections that follow explain how to perform operations, mostly using the Outline View tree, however these same operations can also be completed using the **Cell Zone Conditions** or **Boundary Conditions** task page. The sections also explain how to use the mouse and the graphics display in conjunction with the dialog box.

Note — You can modify individual boundary conditions and cell zones by expanding the **Cell Zones** and **Boundary Conditions** branches in the tree, and right-clicking the boundary condition or cell zone you want to modify.

7.1.3. Changing Cell and Boundary Zone Types

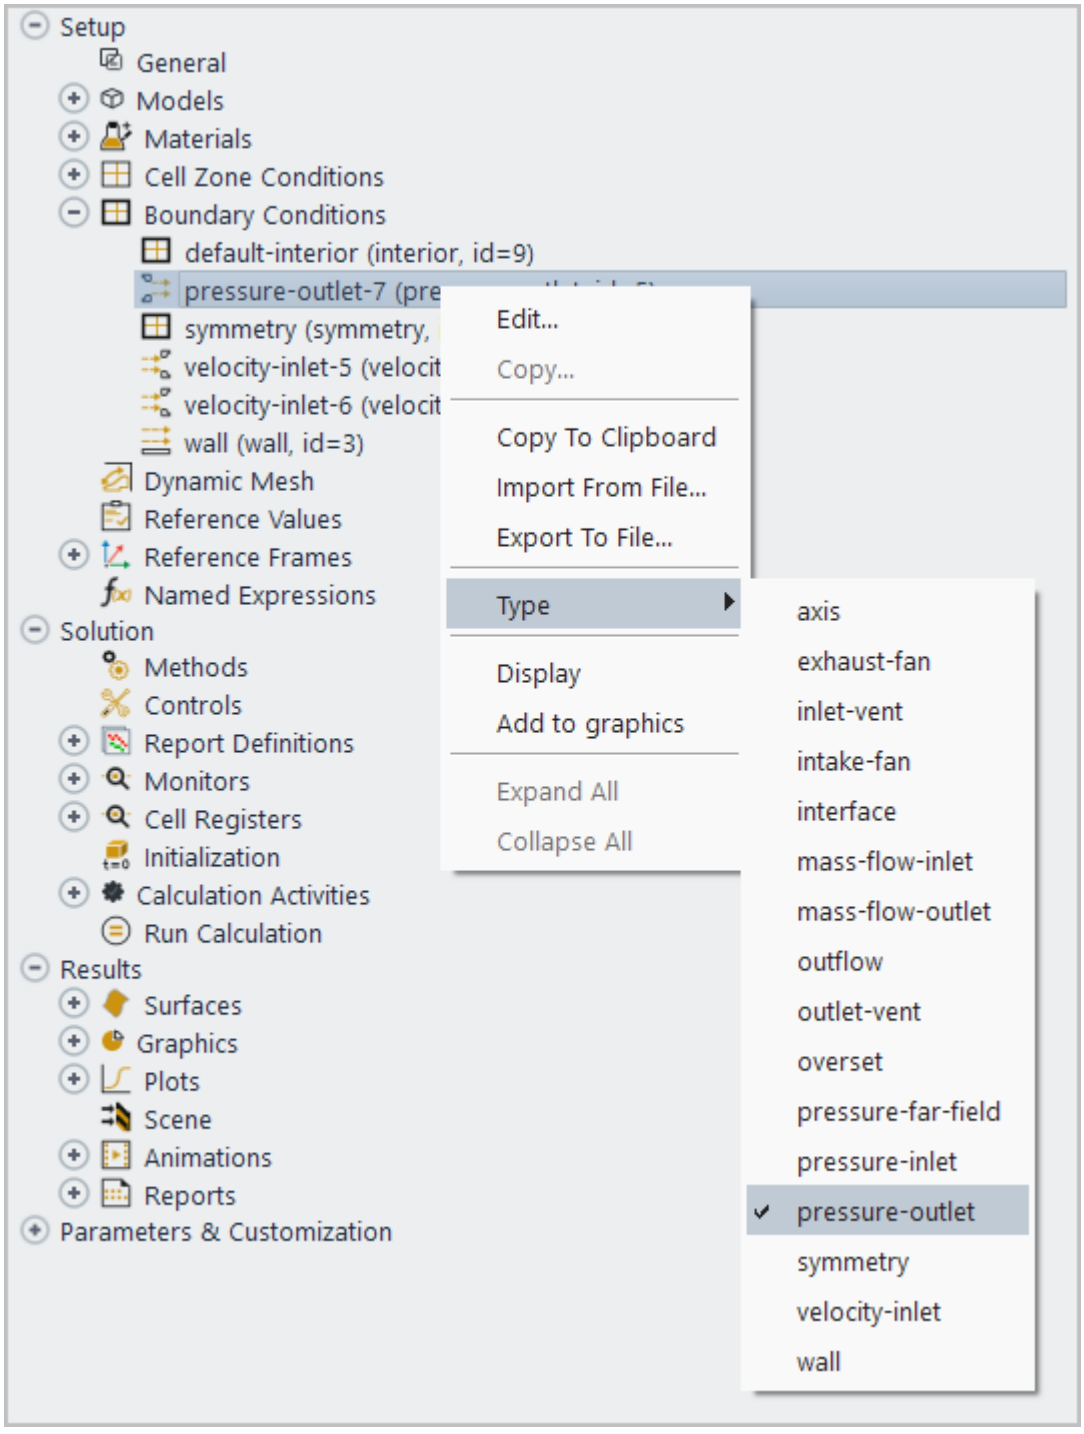
Before you set any cell zone or boundary conditions, you should check the zone types of all boundary zones and change any if necessary. For example, if your mesh includes a pressure inlet, but you want to use a velocity inlet instead, you will need to change the pressure-inlet zone to a velocity-inlet zone. Note that external and internal boundary zones (as listed in Table 7.1: Zone Types by Category (p. 1278)) can only be changed to a zone of the same category.

The steps for changing a zone type using the graphical user interface are as follows:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Select the boundary or cell zone in the tree (under **Setup**/**Boundary Conditions** or **Setup**/**Cell Zone Conditions**). Note that you can select multiple zones by holding the **Shift** or **Ctrl** keys when selecting, though you must ensure that all of the selections are of the same category.

2. Right-click a selected boundary or cell zone, and select the correct zone type from the **Type** sub-menu.



You can also change the zone type using either the `define/boundary-conditions/zone-type` or the `define/boundary-conditions/modify-zones/zone-type` text command. To

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

change the type for multiple zones of the same category through a single action, you can enter a list of names or IDs contained within a pair of parentheses at the prompt, as shown in the following example (which changes zone 4 and 9 to be pressure inlets):

```
>
define/boundary-conditions/zone-type
zone id/name/list []
(4 9)
external-type>
pressure-inlet
```

When changing the cell or boundary zone type, note the following:

- For zones that have a default name (that is, <*type*>-<*ID*>, <*type*>_<*ID*>, or <*type*>.<*ID*>), the <*type*> in the name will be changed automatically to match the new type.
- When you have a large number of internal boundary zones that you want to change to or from a wall / shadow pair, it is recommended that you change their type with a single action (either by multi-selecting in the tree or by using parentheses at the text command prompt); this will greatly reduce the processing time associated with the change.
- When changing a wall / shadow pair to one of the other internal types (fan, interior, porous jump, radiator, or RANS/LES interface), you can select either the wall or the wall-shadow to change. In either case, the resulting zone will retain the ID and orientation of the wall zone and the wall-shadow zone will be deleted.
- Note that you cannot use this method to change zone types to or from the periodic type, since additional restrictions exist for this boundary type. For details on creating or decoupling periodic zones, see Creating Periodic Zones and Interfaces (p. 1246) or Decoupling Periodic Zones (p. 1249), respectively.
- If you are using one of the general multiphase models (VOF, mixture, or Eulerian), the procedure for changing types is slightly different. See Steps for Setting Boundary Conditions (p. 2953) for details.

7.1.4. Setting Cell Zone and Boundary Conditions

In Ansys Fluent, boundary conditions are associated with zones, not with individual faces or cells. If you want to combine two or more zones that will have the same boundary conditions, see Merging Zones (p. 1238) for information about merging zones.

To set cell zone and boundary conditions for a particular zone, perform one of the following sequences:

1. Right-click the name of zone in the tree (under **Setup**/**Boundary Conditions** or **Setup**/**Cell Zone Conditions**).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Select **Edit...**.

Note:

You can group **Boundary Conditions** based on adjacency, allowing you to see which boundaries belong to the same cell zone. To do this, right-click the **Boundary Conditions** branch in the **Outline View** tree and select **Group By**/**Adjacency**.

Setup → **Boundary Conditions** **Group By** → **Adjacency**

---

or

1. Select the zone from the **Zone** list in the **Cell Zone Conditions** or **Boundary Conditions** task page.

2. Click the **Edit...** button.

The dialog box for the selected cell or boundary zone will open, and you can specify the appropriate conditions.

Important:

If you are using one of the general multiphase models (VOF, mixture, or Eulerian), the procedure for setting conditions is slightly different from that described above. See Steps for Setting Boundary Conditions (p. 2953) for details.

You can use the text command: `define/boundary-conditions/set/` to define one or more settings at a single or multiple boundaries/cell zones of a given type. This facilitates quick and efficient setup of cell/boundary conditions for cases with large numbers of zones.

To edit multiple boundaries you can either provide a list of boundary names / IDs enclosed in parenthesis:

```
                /define/boundary-conditions/set>
                wall
                (rotor-hub rotor-shroud rotor-blade-1 rotor-blade-2 stator-hub stator-shroud stator-blade-1 stato
zone(s) to set boundary conditions(1) [rotor-hub]
                (rotor-blade-1 rotor-blade-2)
```

or you can use a wildcard pattern for the boundary names:

```
                /define/boundary-conditions/set>
                wall
                (rotor-hub rotor-shroud rotor-blade-1 rotor-blade-2 stator-hub stator-shroud stator-blade-1 stato
zone(s) to set boundary conditions(1) [rotor-hub]
                (rotor-blade-*)
```

For additional information on formatting lists in the console, see Lists.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

After entering the zone(s) you want to change you will be prompted for what setting to change. Pressing **Enter** will list the available settings.

When you have changed all of the desired settings, press **q** to exit the `define/boundary-conditions/set/<type>` command. Note that some settings will not take effect until after you have exited the command, by pressing **q**.

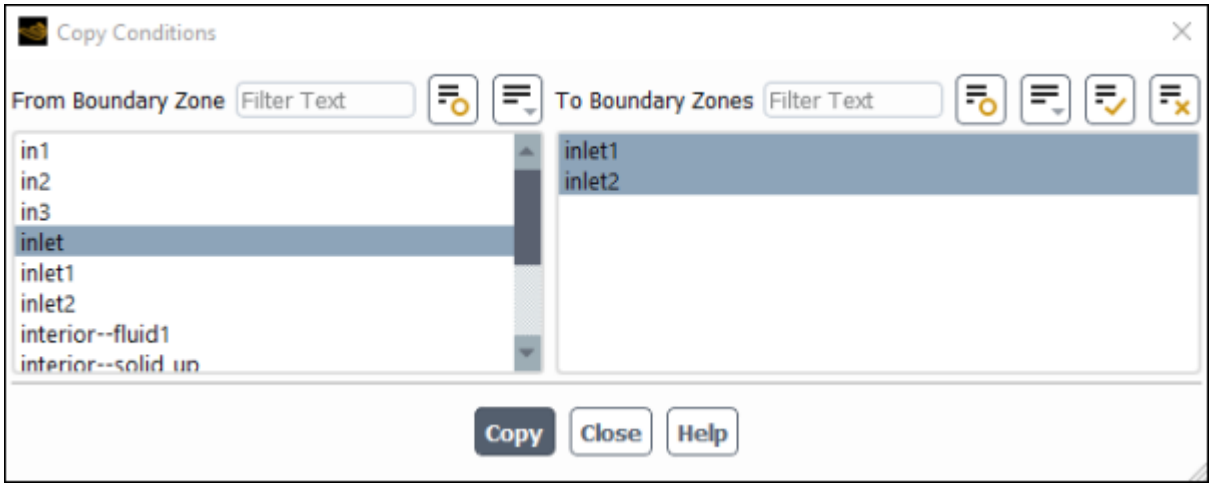
7.1.5. Copying Cell Zone and Boundary Conditions

You can copy cell zones and boundary conditions from one zone to other zones of the same type. If, for example, you have several wall zones in your model and they all have the same boundary conditions, you can set the conditions for one wall, and then simply copy them to the others.

The procedure for copying cell zone or boundary conditions is as follows:

1. Right-click the name of zone in the tree that you want to copy (under **Setup**/**Boundary Conditions** or **Setup** / **Cell Zone Conditions**) and select **Copy...**. This will open the **Copy Conditions** dialog box (Figure 7.2: The Copy Conditions Dialog Box (p. 1283)).

   Figure 7.2: The Copy Conditions Dialog Box



2. In the **From Cell Zone** or **From Boundary Zone** list, confirm that the zone that has the conditions you want to copy is selected.

3. In the **To Cell Zones** or **To Boundary Zones** list, select the zone or zones to which you want to copy the conditions.

4. Click **Copy**. Ansys Fluent will set *all* of the cell zones or boundary conditions for the zones selected in the **To Cell Zones** or **To Boundary Zones** list to be the same as the conditions for the zone selected in the **From Cell Zone** or **From Boundary Zone** list. (You cannot copy a subset of the conditions, such as only the thermal conditions.)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

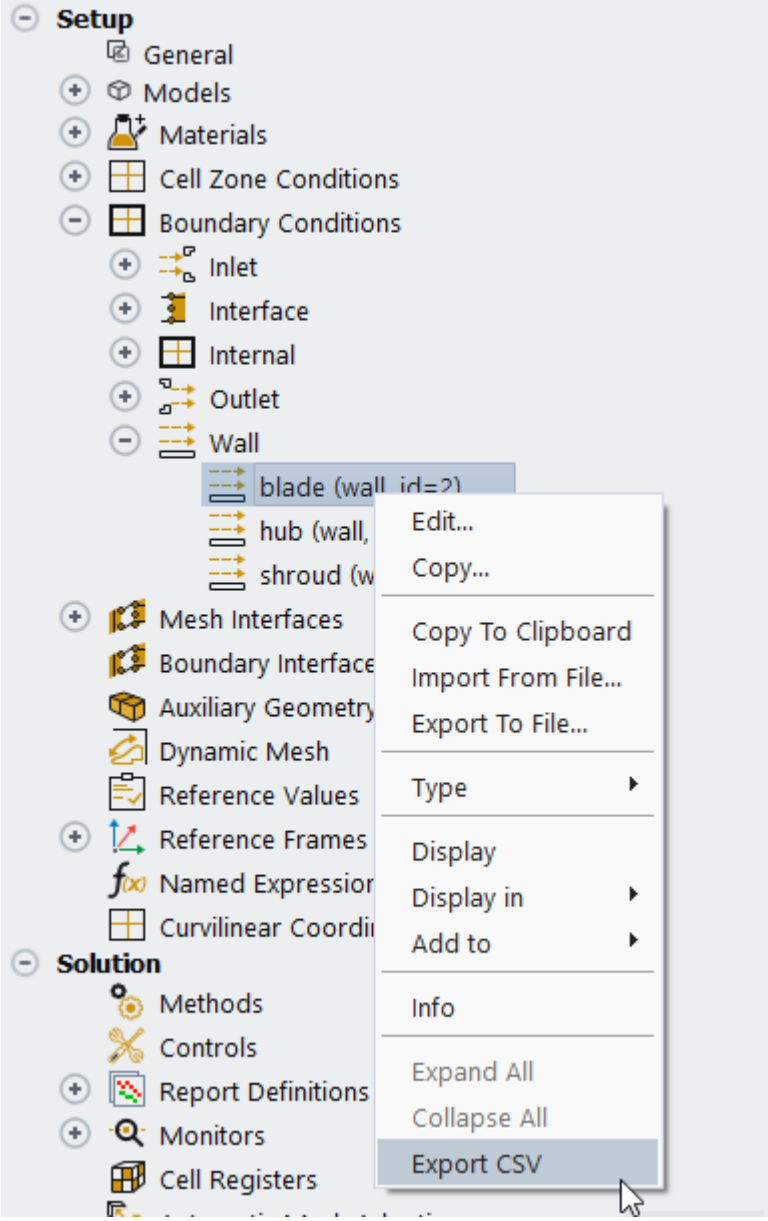
Note that you cannot copy conditions from external walls to internal (that is, two-sided) walls, or vice versa, if the energy equation is being solved, since the thermal conditions for external and internal walls are different.

Important:

If you are using one of the general multiphase models (VOF, mixture, or Eulerian), the procedure for copying boundary conditions is slightly different. See Steps for Copying Cell Zone and Boundary Conditions (p. 2970) for details.

7.1.6. Exporting Boundary Zones in CSV Format

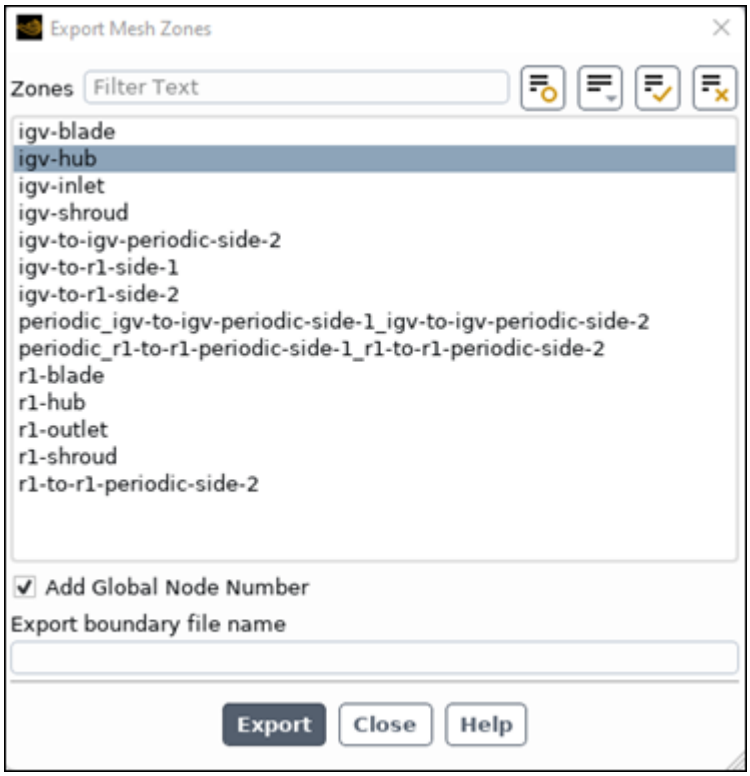
You can export a `.csv` file containing data from one or more boundaries by right-clicking one or more boundaries and selecting **Export CSV**.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Clicking **Export CSV** for one or more boundaries opens the **Export Mesh Zones** dialog box as shown in Figure 7.3: Export Mesh Zones Dialog Box (p. 1285).

Figure 7.3: Export Mesh Zones Dialog Box



1. Under **Zones**. select the boundary zone(s) from which you would like to export mesh data.

2. Optionally select **Add Global Node Number**.

   Adds the "`Global Node Number`" column to the exported data. Doing so can help with the identification of shared nodes, for example, nodes shared among multiple exported surfaces. In particular, if you want the System Coupling Service to be able to identify which nodes are shared between multiple surfaces in the exported CSV data, you should select **Add Global Node Number**. For additional information, see System Coupling's Mapping Capabilities in the *System Coupling User's Guide*.

3. Under **Export boundary file name**, provide a file name for the exported mesh data. Note that `.csv` is appended to the name you provide.

4. Click **Export** to write the `.csv` to your working directory.

The same functionality is provided by entering the following command in the console and following the prompts:

```
/define/turbo-model/export-boundary-mesh
```

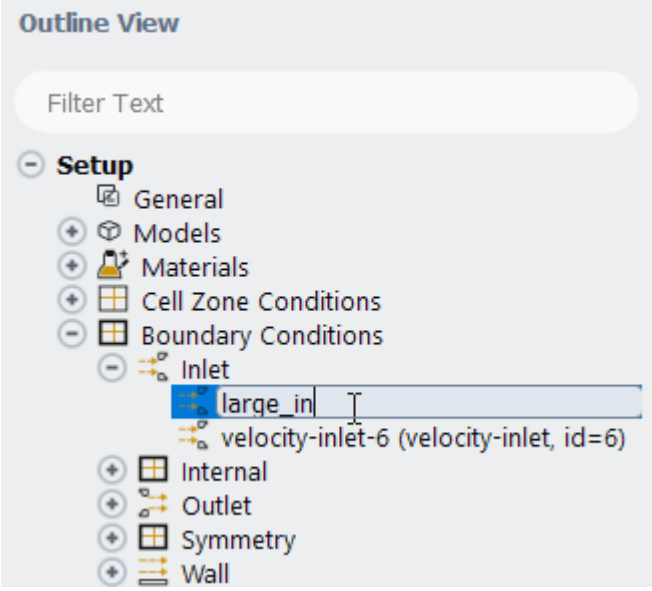
When exporting CSV data, the resulting `.csv` file contains surface meshes in a form that can be imported into CFX-Pre or CFD-Post as a user surface, or used in System Coupling mapping (see Aerodynamic Damping Analysis in the *System Coupling User's Guide*).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.1.7. Changing Cell or Boundary Zone Names

The default name for a zone is *<type>* **-** *<ID>* (for example, **pressure-inlet-7**). In some cases, you may want to assign more descriptive names to the boundary zones. If you have two pressure-inlet zones, for example, you might want to rename them **small-inlet** and **large-inlet**. (Changing the name of a zone will *not* change its type. Instructions for changing a zone's type are provided in Changing Cell and Boundary Zone Types (p. 1279).)

You can rename boundaries and cell zones directly within the tree, by selecting the zone that you want to rename, then clicking the name (slow double-click).



Alternatively, you can rename a zone by following these steps:

1. Right-click the name of zone in the tree (under **Setup**/**Boundary Conditions** or **Setup**/**Cell Zone Conditions**).
2. Select **Edit...** to open the dialog box for the selected zone.
3. Enter a new name under **Zone Name**.
4. Click the **OK** button.

Note:

If you specify a non-default name for a zone and then change its type, the name you specified will be retained; the automatic name change that accompanies a change in type occurs only for those with the default name.

7.1.8. Defining Non-Uniform Cell Zone and Boundary Conditions

Most conditions at each type of boundary zone can be defined as profile functions instead of constant values. You can use a profile contained in an externally generated profile file, or a function that you

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

create using a user-defined function (UDF). Profiles are described in Profiles (p. 1540), and user-defined functions are described in the separate Fluent Customization Manual.

7.1.9. Defining and Viewing Parameters

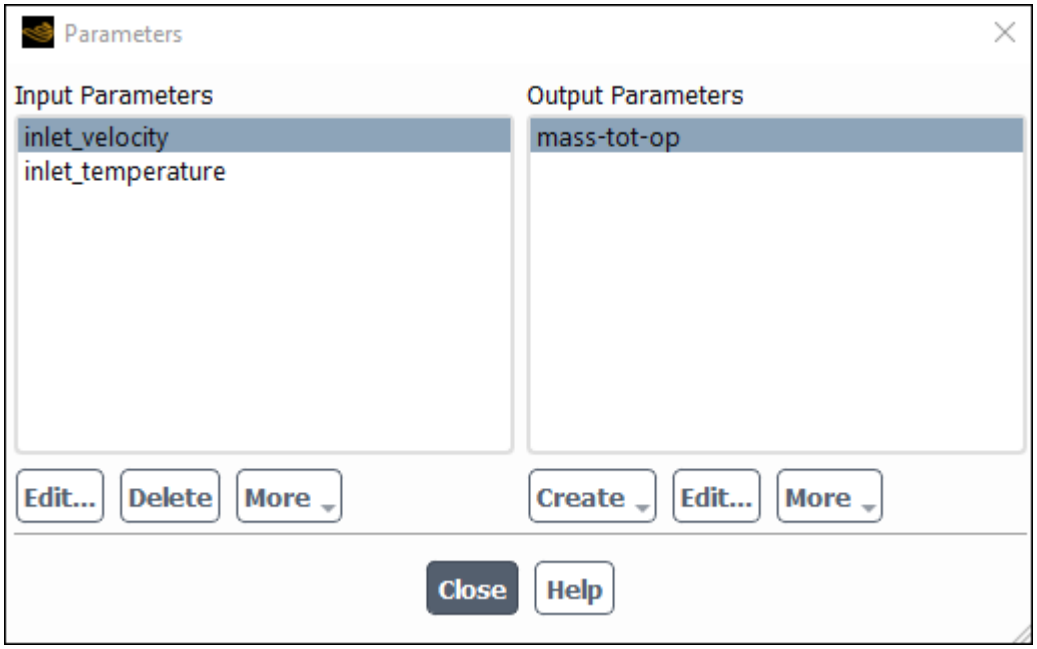
You can define a series of cases based on a set of parametric values. These parameters may be defined for numeric cell zone and boundary condition settings. This is especially useful if you are using Workbench and performing parametric studies (optimization), comparing cases with different boundary settings; information about such usage can be found in see Working with Parameters and Design Points in the Workbench User's Guide. If you are not running Ansys Fluent through Workbench, then you can use the parameter settings to define the same boundary condition value to different boundaries having the same units, or to use the **Gradient-Based Optimizer** to optimize a geometry for multiple objectives at multiple operating conditions (see Using the Gradient-Based Optimizer (p. 4531)).

Note:

For more information about using parameters with Ansys Fluent in Ansys Workbench, see Working With Input and Output Parameters in Workbench in the separate Fluent in Workbench User's Guide.

The parameters that you have defined in the various boundary condition dialog boxes are accessed by clicking the **Parameters...** button in the **Cell Zone Conditions** or **Boundary Conditions** task page. The **Parameters** dialog box will open, as shown in Figure 7.4: The Parameters Dialog Box (p. 1287), listing all of the input parameters that you have created in the various boundary condition dialog boxes.

Figure 7.4: The Parameters Dialog Box



In the **Parameters** dialog box, under the **Input Parameters** list, you can

- Edit the input properties using the **Parameter Expression** dialog box, which is the same dialog box used to create parameters. This dialog box can also be accessed by selecting **New Input Parameter...** from the drop-down lists in the boundary conditions dialog boxes, as described later in this section.

  Important:

  If you are using Ansys Fluent in Ansys Workbench, you cannot edit the input parameters, you can only view them. For more information, see the separate Ansys Fluent in Ansys Workbench User's Guide.

- Delete input parameters that are not assigned to a setting.
- More options exist under the **More** drop-down list (see Working With Advanced Parameter Options (p. 1291)):

  Use in Scheme Procedure

  displays the Use Input Parameter in Scheme Procedure Dialog Box (p. 5287) where you can apply an input parameter using a Scheme procedure.

  Use in UDF

  displays the Use Input Parameter for UDF Dialog Box (p. 5288) where you can make an input parameter available in a user-defined function.

In the **Parameters** dialog box, under the **Output Parameters** list, you can also

- Create output parameters. These are single values generated by existing reports or monitors. You can generate the output parameters from report definitions (surface, volume, lift, drag, and so on). These output parameters are discussed in greater detail in Creating Output Parameters (p. 4099).
- Edit existing output parameters.
- More options exist under the **More** drop-down list:

  Delete

  removes the selected output parameter from the list of **Output Parameters**.

  Rename

  allows you to edit the name of the output parameter through the **Rename** dialog box.

  Print to Console

  will output values to the console window. If you select multiple output parameters, then the output includes values from multiple output parameters.

  Print All to Console

  outputs the values from all output parameters to the console window.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Write...

allows you to store the output to a file. A dialog box is displayed allowing you to provide a file name.

Write All...

prompts you for a file name and then writes the values for all of the output parameters to a file.

Important:

Changing the units for a quantity changes the value for any input parameter using that quantity.

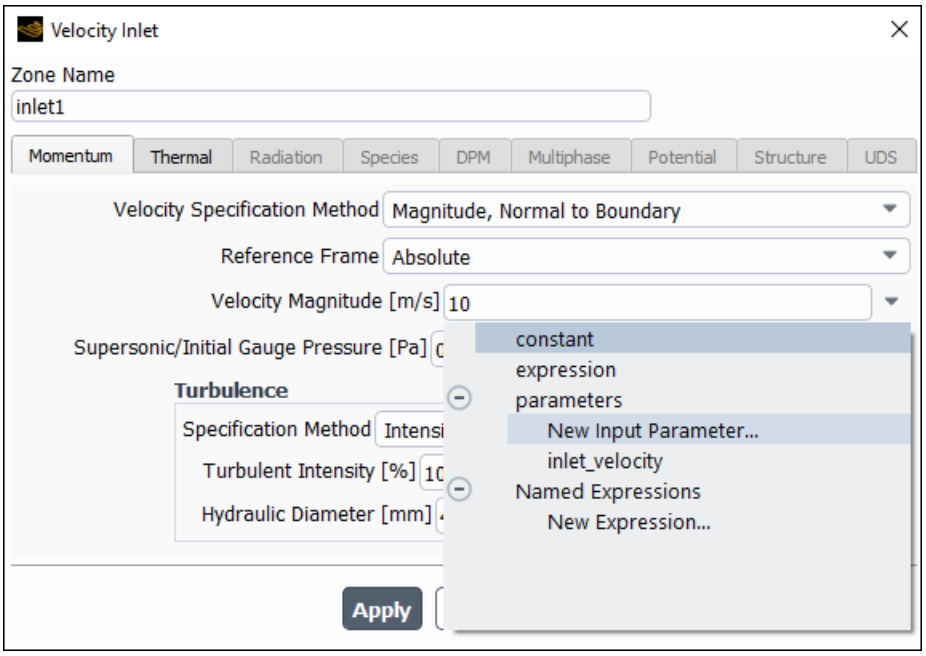
Note:

Various Ansys Fluent setup-related input quantities (of type real and profile) can be assigned to an input parameter (indicated by the **New Input Parameter...** option in the corresponding drop-down list or menu next to the field). Clicking this option opens the Figure 7.6: The Parameter Expression Dialog Box (p. 1290) where you can create the input parameter.

7.1.9.1. Creating a New Parameter

You can create a new cell zone or boundary condition parameter, as shown in Figure 7.5: The New Input Parameter... Selection (p. 1289).

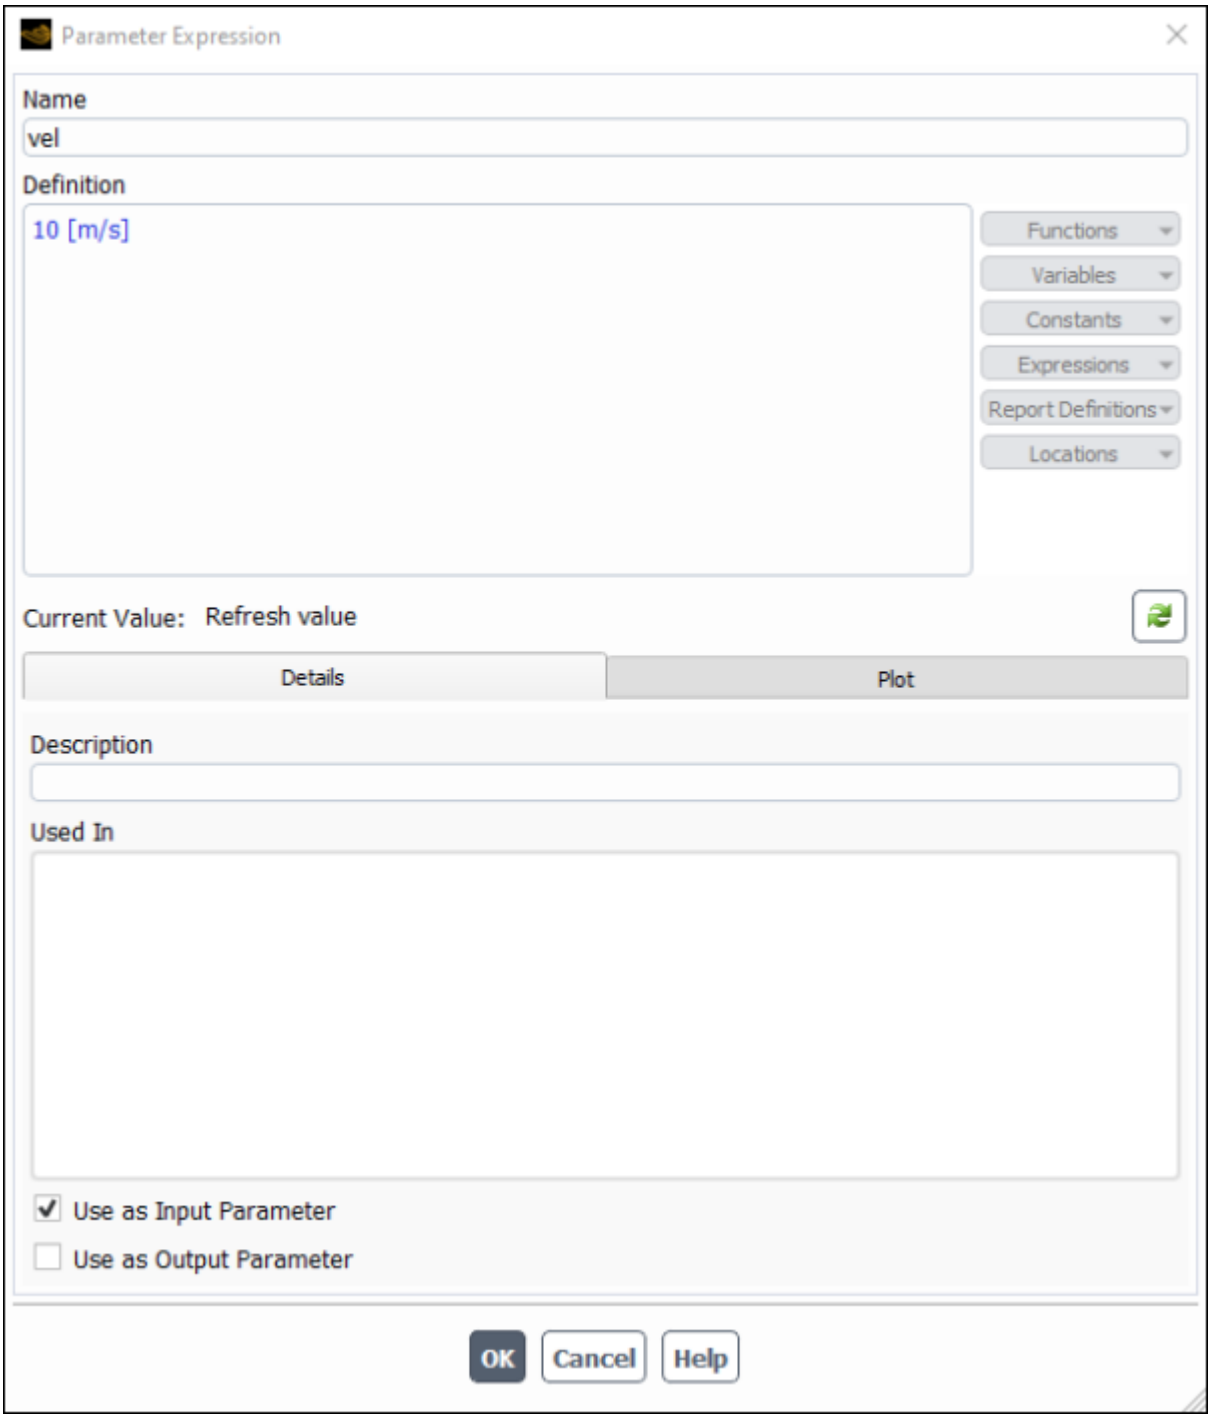
Figure 7.5: The New Input Parameter... Selection



When you select **New Input Parameter...** from the drop-down list, the **Parameter Expression** dialog box (Figure 7.6: The Parameter Expression Dialog Box (p. 1290)) will open where you will

- Enter the **Name** of the parameter expression.
- Specify the **Definition** as a constant.
- The **Used In** field displays information about where the parameter is utilized. Note that this field will be populated after you create an input parameter.

Figure 7.6: The Parameter Expression Dialog Box



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Once the parameter is defined in the **Parameter Expression** dialog box, the name of the parameter will appear in the drop-down list of the property you are defining, as seen in Figure 7.5: The New Input Parameter... Selection (p. 1289).

Important:

Input parameter expressions must be directly defined as a constant value including appropriate units; it may not reference another expression.

Note:

Ansys Fluent automatically creates generic default names for new input and output parameters (for example, `parameter_1`, `parameter_2`, `parameter_3`, and so on) If a parameter is deleted, the default name is not reused. For example, if you have `parameter_1`, `parameter_2`, and `parameter_3`, then delete `parameter_2` and create a new parameter, the default name for the new parameter will be `parameter_4`.

7.1.9.2. Working With Advanced Parameter Options

Various Ansys Fluent setup related input quantities can be assigned to an input parameter. You can define a series of simulations based on a set of parametric values that are managed both in Ansys Fluent and in Workbench. These parameters may be defined for numeric cell zone and boundary condition settings using the **New Input Parameter…** option in the corresponding drop-down list or menu adjacent to a specific input setting. However, various Ansys Fluent settings are not supported by these methods.

You can mitigate this limitation using input parameters through Scheme procedures and user-defined functions (UDFs), and define input parameters for various Ansys Fluent simulation related settings.

7.1.9.2.1. Defining Scheme Procedures With Input Parameters

7.1.9.2.2. Defining UDFs With Input Parameters

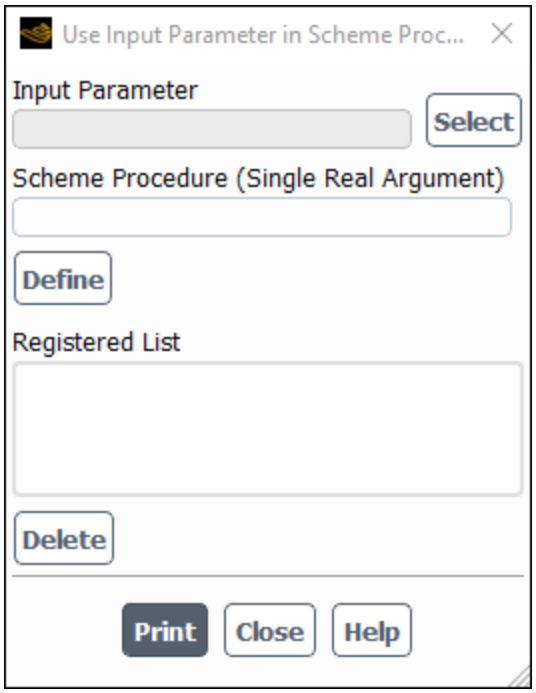
7.1.9.2.3. Using the Text User Interface to Define UDFs and Scheme Procedures With Input Parameters

7.1.9.2.1. Defining Scheme Procedures With Input Parameters

To use a Scheme procedure with input parameters, in the **Parameters** dialog box under **Input Parameters**, select **More**, then choose **Use in Scheme Procedure** to display the Use Input Parameter in Scheme Procedure Dialog Box (p. 5287) where you can register the input parameters that can be used in Scheme procedures during calculations. A text user interface command is also available, described in Using the Text User Interface to Define UDFs and Scheme Procedures With Input Parameters (p. 1294).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.7: Use Input Parameter in Scheme Procedure Dialog Box



Use the **Select** button to open the Select Input Parameter Dialog Box (p. 4928) where an input parameter can be chosen. Enter a **Scheme Procedure** name or body starting with `lambda` that should receive a real argument (the value of the selected input parameter). For example, if the following Scheme procedure called `my-funct` is defined as a Scheme file that gets loaded into the current session,

```
(define my-funct
 (lambda (value )
  (ti-menu-load-string (format #f "/solve/set/under-relaxation/pressure ~g" value))))
```

then enter `my-funct` for the **Scheme Procedure**. Otherwise, you can directly enter the following code for the **Scheme Procedure**:

```
(lambda (value)(ti-menu-load-string (args->string '/solve/set/under-relaxation/pressure value)))
```

Click **Define** to populate the **Registered List**. Use **Delete** to delete the use of the selected input variable, but not the associated input parameter (the input parameter has to be deleted separately in the **Parameters** dialog box). Use **Print** to print out details of the registered input parameters.

Important:

While writing Scheme procedures, you should use the "args->string" help procedure instead of using double quotes. For example:

```
(lambda ( value1)
 (display (args->string 'Changing-Theta-Divisions-value=   value1))
 (ti-menu-load-string
    (args->string '/define/models/radiation/discrete-ordinates? 'yes value1  '_  '_  '_)) )
```

Alternatively, you could also write:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
(lambda ( value1)
 (display (args->string 'Changing-Theta-Divisions-value=  value1))
 (ti-menu-load-string
   (apply args->string `(/define/models/radiation/discrete-ordinates? yes ,value1  _  _  _) )) )
```

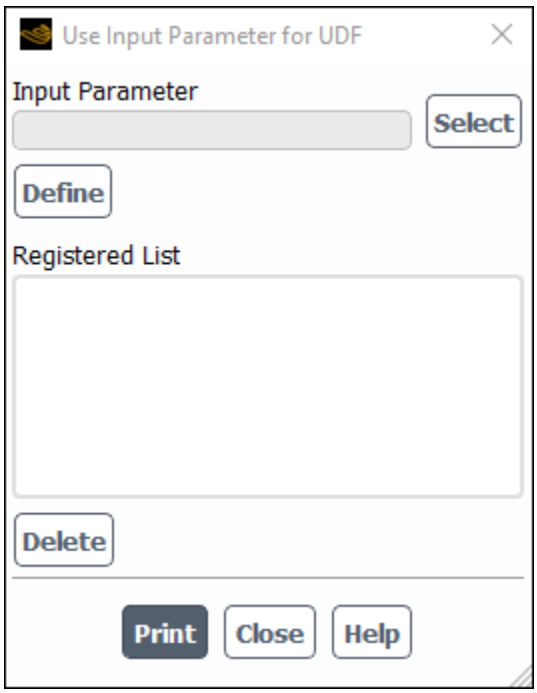
where the ` character after `args->string` is the grave accent character (not a single quote) and the _ character stores the default value of the current text user interface prompt. Note that the first occurrence of `value1` is the Scheme variable, while the second occurrence of `value1` will be replaced by the value stored in the variable. This method eliminates the need to specify a single quote for all arguments.

Also note that if you enter a scheme procedure body in the **Use Input Parameter in Scheme Procedure** dialog box, you should combine the scheme procedure lines into one single line.

7.1.9.2.2. Defining UDFs With Input Parameters

To use a UDF with input parameters, in the **Parameters** dialog box under **Input Parameters**, select **More**, then choose **Use in UDF** to display the Use Input Parameter for UDF Dialog Box (p. 5288) where you can register the input parameters that can be used in UDF functions during calculations. A text user interface command is also available, described in Using the Text User Interface to Define UDFs and Scheme Procedures With Input Parameters (p. 1294).

Figure 7.8: Use Input Parameter for UDF Dialog Box



Use the **Select** button to open the Select Input Parameter Dialog Box (p. 4928) where an input parameter can be chosen. Click **Define** to populate the **Registered List**. Use **Delete** to delete the use of the selected input variable, but not the associated input parameter (the input parameter has to be deleted separately in the **Parameters** dialog box). Click **Print** to print out the parameter ID of the registered input parameter. This ID should be used to access the value of the parameter in UDF.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

By registering the input parameter, Ansys Fluent knows that this input parameter is being used by a UDF. In the UDF C function, you can access the registered input parameter value using the `RP_Get_Input_Parameter` macro. For example,

```
real value = RP_Get_Input_Parameter(“real-4”),
```

where `real-4` is an input parameter ID obtained using the **Print** feature.

7.1.9.2.3. Using the Text User Interface to Define UDFs and Scheme Procedures With Input Parameters

The `/define/parameters/input-parameters/advance/use-in` text interface command can also be used to define input parameters and Scheme procedures and user-defined functions.

The Scheme procedures can use other text user interface (TUI) commands in Ansys Fluent to change the desired simulation settings in a parametric manner. Each numerical component of the TUI command string can be marked and treated as a parameter. Setting up advanced input parameters requires using Scheme functions that use text interface commands to apply new values. Once defined, these input parameters are displayed in the **Parameters** dialog box alongside other input parameters. The input parameter passes a constant numeric value to the registered/provided Scheme function. Therefore, the associated Scheme function (and corresponding Ansys Fluent text command) uses the constant parameter values using the units that were already defined for the designated text command quantity.

`/define/parameters/input-parameters/advance`

Enter the advanced input parameters menu.

`use-in/`

Allows you to use an input parameter in a Scheme procedure or in a UDF. The following examples demonstrates how to use an input parameter using a Scheme procedure. The Scheme procedure body can be written at the prompt itself:

```
                                                /define/parameters/input-parameters/advance>
                                                use-in
                                                Select type:>
                                                scheme-proc
                                                Name of parameter ["parameter-1"]
parameter-1 value [0]
                                                0.3
                                                Enter the name/body of apply-function [()]
                                                (lambda (value )
        (ti-menu-load-string (format #f "/solve/set/under-relaxation/pressure ~g" value)))
```

or it can be written in a Scheme file (for example, `my-funct`)

```
                                                /define/parameters/custom-input-parameters>
                                                use-in
                                                Select type:>
                                                scheme-proc
                                                Name of parameter ["parameter-1"]
parameter-1 value [0]
                                                0.3
                                                Enter the name/body of apply-function [()]
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
                                                  my-funct
```

where the `my-funct` Scheme file contents are:

```
(define my-funct
    (lambda (value )
        (ti-menu-load-string (format #f "/solve/set/under-relaxation/pressure ~g" value))))
```

The following example demonstrates how to use an input parameter using a UDF:

```
                                                  /define/parameters/input-parameters/advance>
                                                  use-in
                                                  Select type:>
                                                  udf-side
                                                  Name of parameter ["parameter-1"]
parameter-1 value [0]
                                                  0.3
```

delete

Deletes the use of the selected input variable, but not the associated input parameter (the input parameter has to be deleted separately). Using the wildcard '*' allows you to delete all custom input variable at once.

list

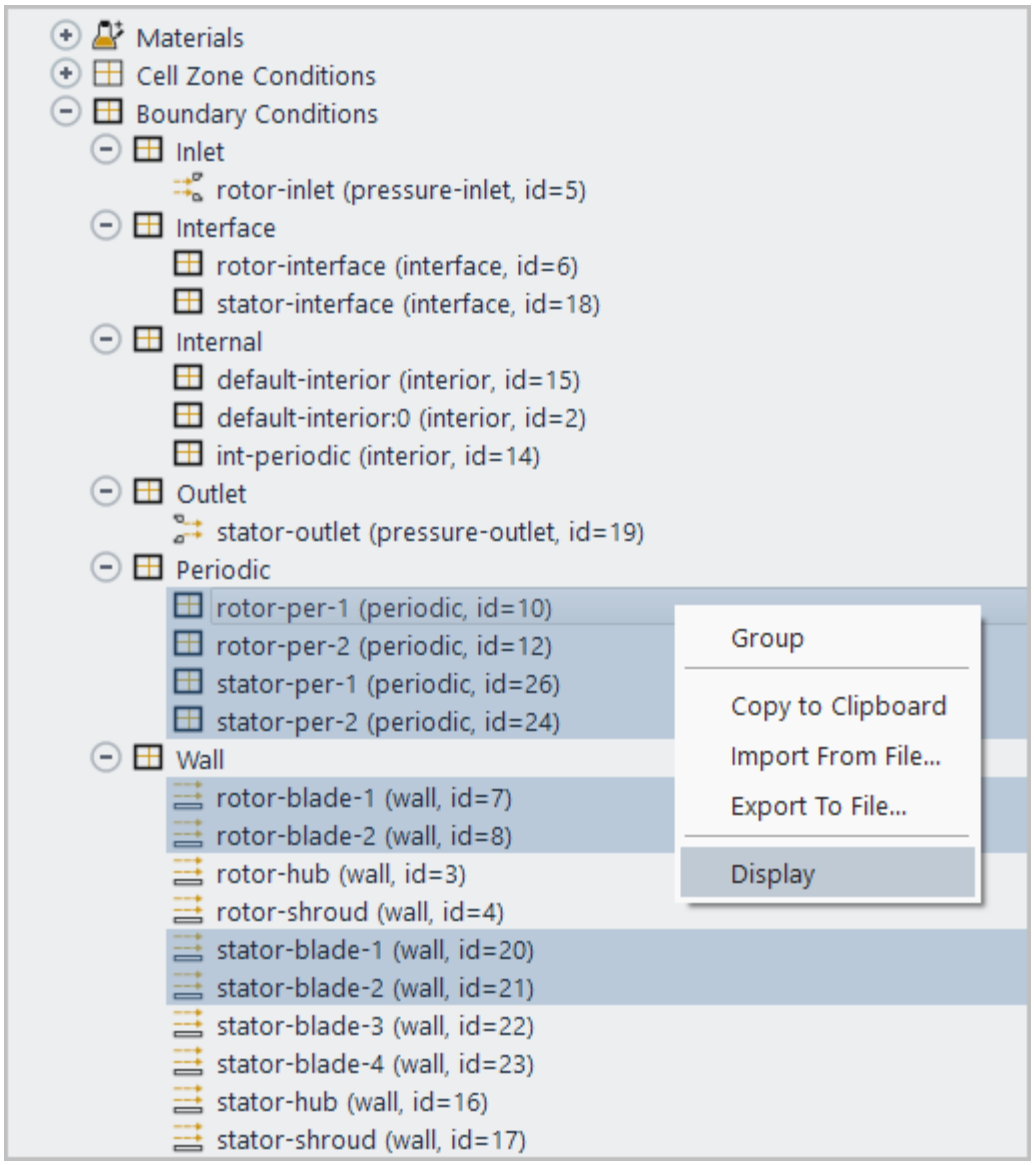
Shows usage of input parameters for Scheme procedures and for UDFs

7.1.10. Selecting Cell or Boundary Zones in the Graphics Display

During setup you will want to display boundary conditions, which can be accomplished using the Mesh Display Dialog Box (p. 4636). You also have the option to highlight boundaries in the tree, right-click them, and select **Display**, **Display in** or **Add to**. This feature is particularly useful if you are setting up a problem for the first time or if you want to visually confirm the location of a particular boundary condition.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

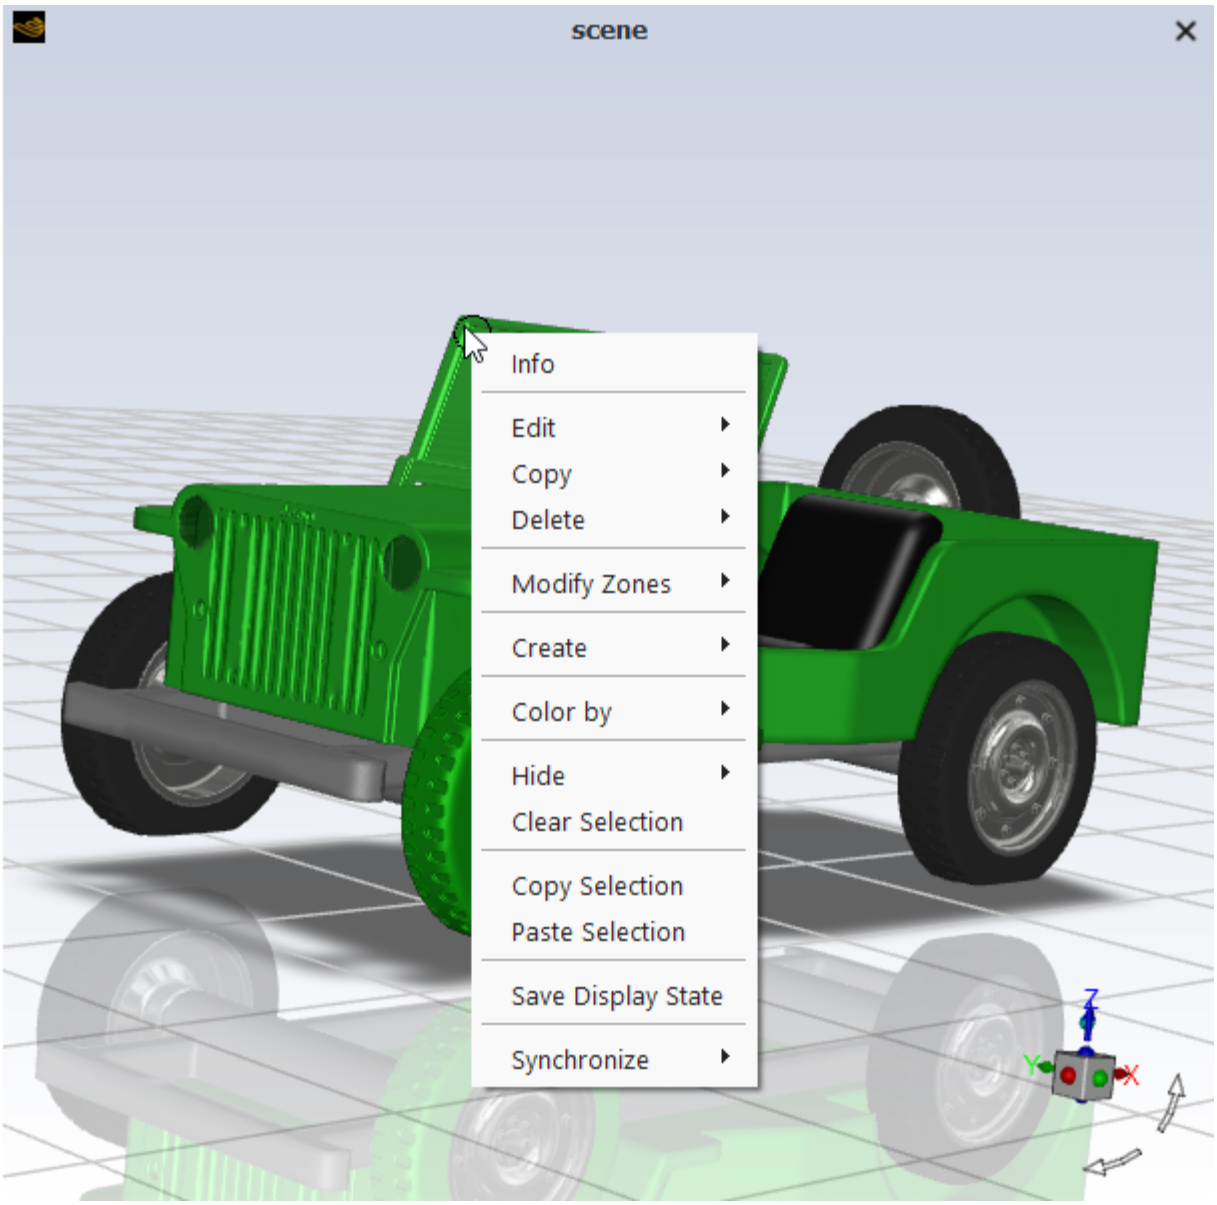
Figure 7.9: Selecting Multiple Boundaries for Display in the Graphics Window



The boundary description in the tree includes the zone IDs, which can help you differentiate the zones. You can also right-click selected boundaries in the graphics window to perform a number of options including printing information about the boundaries (surface IDs, zone IDs, surface groups, and so on), fusing zones, and creating graphics objects. For example, refer to Figure 7.10: Example Operations for Multiple Selected Surfaces in the Graphics Window (p. 1297), which shows some operations that are available for the selected surfaces (highlighted in light green).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.10: Example Operations for Multiple Selected Surfaces in the Graphics Window



7.1.11. Operating and Periodic Conditions

The **Cell Zone Conditions** and **Boundary Conditions** task pages allow you to access the **Operating Conditions** dialog box, where you can set the operating pressure, reference pressure location, include the effects of gravity, and specify other operating variables, as discussed in Modeling Basic Fluid Flow (p. 1709).

Setup → **Cell Zone Conditions** → **Operating Conditions...**

Setup → **Boundary Conditions** → **Operating Conditions...**

The **Periodic Conditions** dialog box can be accessed from the **Boundary Conditions** task page. For a detailed description of this dialog box's inputs, refer to Periodic Flows (p. 1719).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setup → **Boundary Conditions** → **Periodic Conditions...**

7.1.12. Saving and Reusing Cell Zone and Boundary Conditions

You can save cell zone and boundary conditions to a file so that you can use them to specify the same conditions for a different case, as described in Reading and Writing Boundary Conditions (p. 946).

7.2. Cell Zone Conditions

Cell zones consist of fluids and solids. Porous zones and 3D fans in Ansys Fluent are treated as fluid zones. A detailed description of the various cell zones is given in the sections that follow.

7.2.1. Fluid Conditions
7.2.2. Solid Conditions
7.2.3. Porous Media Conditions
7.2.4. 3D Fan Zones
7.2.5. Fixing the Values of Variables
7.2.6. Locking the Temperature for Solid and Shell Zones
7.2.7. Defining Mass, Momentum, Energy, and Other Sources

7.2.1. Fluid Conditions

A fluid zone is a group of cells for which all active equations are solved. The only required input for a fluid zone is the type of fluid material. You must indicate which material the fluid zone contains so that the appropriate material properties will be used.

Important:

If you are modeling multiphase flow, you will not specify the materials here; you will choose the phase material when you define the phases, as described in Defining the Phases for the VOF Model (p. 3005).

Important:

If you are modeling species transport and/or combustion, you can specify the material as either a mixture or a fluid. The mixture material has to be the same as that specified in the **Species Model** dialog box when you enable the model. The fluid zones, being of different material types, must not be contiguous.

Optional inputs allow you to set sources or fixed values of mass, momentum, heat (temperature), turbulence, species, and other scalar quantities. You can also define motion for the fluid zone. If there are rotationally periodic boundaries adjacent to the fluid zone, you must specify the rotation axis. If you are modeling turbulence using one of the k - ε models, the k - ω model, or the Spalart-Allmaras

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

model, you can choose to define the fluid zone as a laminar flow region. If you are modeling radiation using the DO model, you can specify whether or not the fluid participates in radiation.

Warning:

In general, disabling **Participates in Radiation** for fluid zones is not recommended, as it can produce erroneous results. There are rare cases when it is acceptable: for example, if the domain contains multiple fluid zones, disabling this option for zones where radiation is negligible may save computational time without affecting the results.

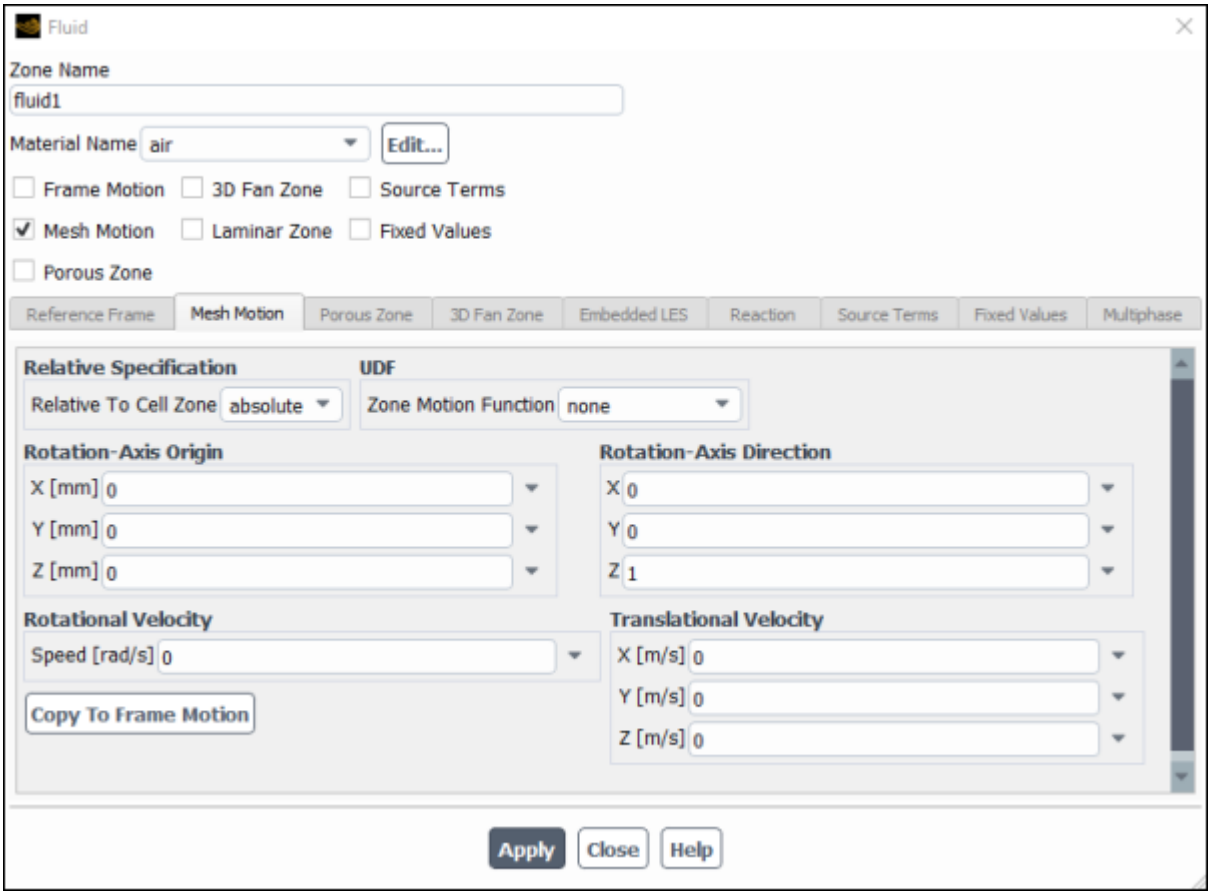
Important:

For information about porous zones and 3D fan zones, see Porous Media Conditions (p. 1311) and 3D Fan Zones (p. 1350), respectively.

7.2.1.1. Inputs for Fluid Zones

You will set all fluid conditions in the Fluid Dialog Box (p. 4909) (Figure 7.11: The Fluid Dialog Box (p. 1299)), which is accessed from the **Cell Zone Conditions** task page (as described in Setting Cell Zone and Boundary Conditions (p. 1281)).

Figure 7.11: The Fluid Dialog Box



7.2.1.1.1. Defining the Fluid Material

To define the material contained in the fluid zone, select the appropriate item in the **Material Name** drop-down list. This list will contain all fluid materials database) in the Create/Edit Materials Dialog Box (p. 4833). If you want to check or modify the properties of the selected material, you can click **Edit...** to open the **Edit Material** dialog box; this dialog box contains just the properties of the selected material, not the full contents of the standard **Create/Edit Materials** dialog box.

Important:

If you are modeling species transport or multiphase flow, the **Material Name** list will not appear in the **Fluid** dialog box. For species calculations, the mixture material for all fluid zones will be the material you specified in the Species Model Dialog Box (p. 4716). For multiphase flows, the materials are specified when you define the phases, as described in Defining the Phases for the VOF Model (p. 3005).

7.2.1.1.2. Defining Sources

If you want to define a source of heat, mass, momentum, turbulence, species, or other scalar quantity within the fluid zone, you can do so by enabling the **Source Terms** option. See Defining Mass, Momentum, Energy, and Other Sources (p. 1360) for details.

7.2.1.1.3. Defining Fixed Values

If you want to fix the value of one or more variables in the fluid zone, rather than computing them during the calculation, you can do so by enabling the **Fixed Values** option. See Fixing the Values of Variables (p. 1355) for details.

7.2.1.1.4. Specifying a Laminar Zone

When you are calculating a turbulent flow, it is possible to "turn off" turbulence modeling in a specific fluid zone. To disable turbulence modeling, turn on the **Laminar Zone** option in the **Fluid** dialog box. This is useful if you know that the flow in a certain region is laminar. For example, if you know the location of the transition point on an airfoil, you can create a laminar/turbulent transition boundary where the laminar cell zone borders the turbulent cell zone. This feature allows you to model turbulent transition on the airfoil.

By default, the **Laminar Zone** option will set the turbulent viscosity, μ_t, to zero and disable turbulence production in the fluid zone. Turbulent quantities will still be transported through the zone, but effects on fluid mixing and momentum will be ignored. If you want to keep the turbulent viscosity, you can do so using the text command `define/ boundary-conditions/fluid`. You will be asked if you want to `Set Turbulent Viscosity to zero within laminar zone?`. If your response is `no`, Ansys Fluent will set the production term in the turbulence transport equation to zero, but will retain a nonzero μ_t.

Disabling turbulence modeling in a fluid zone can be applied to all the turbulence models except the Large Eddy Simulation (LES) model.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.2.1.1.5. Specifying a Reaction Mechanism

If you are modeling species transport with reactions, you can enable a reaction mechanism in a fluid zone by turning on the **Reaction** option and selecting an available mechanism from the **Reaction Mechanism** drop-down list. See Defining Zone-Based Reaction Mechanisms (p. 2385) for more information about defining reaction mechanisms.

7.2.1.1.6. Specifying the Rotation Axis

If there are rotationally periodic boundaries adjacent to the fluid zone or if the zone is rotating, either the mesh or its reference frame, you must specify the rotation axis. To define the axis for a moving reference frame problem, set the **Rotation-Axis Direction** and **Rotation-Axis Origin** under the **Reference Frame** tab. To define the axis for a moving mesh problem, set the **Rotation-Axis Direction** and **Rotation-Axis Origin** under the **Mesh Motion** tab.

Note:

If a frame motion and a mesh motion are specified at the same zone and this zone has rotationally periodic boundaries adjacent to it, then both axes have to be coaxial. Otherwise, the periodicity assumption is not valid and you will receive a warning message. In addition, the mesh check will fail.

The cell zone axis is independent of the axis of rotation used by any adjacent wall zones or any other cell zones. For 3D problems, the axis of rotation is the vector from the **Rotation-Axis Origin** in the direction of the vector given by your **Rotation-Axis Direction** inputs for the frame of reference and the mesh motion. For 2D non-axisymmetric problems, you will specify only the **Rotation-Axis Origin**; the axis of rotation is the z -direction vector passing through the specified point. (The z direction is normal to the plane of your geometry so that rotation occurs in the plane.) For 2D axisymmetric problems, you will not define the axis: the rotation will always be about the x axis, with the origin at (0,0).

7.2.1.1.7. Defining Zone Motion

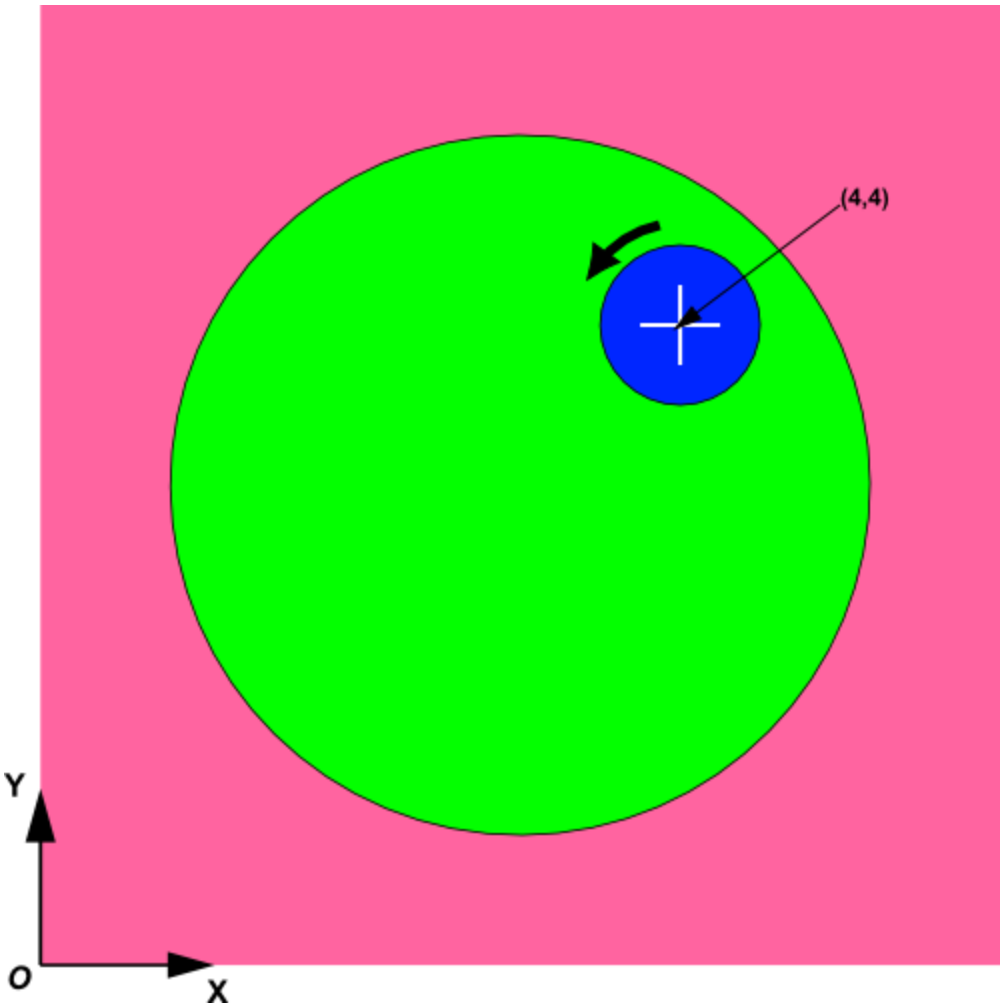
To define zone motion for a moving reference frame (MRF), enable the **Frame Motion** option in the **Fluid** dialog box. Set the appropriate parameters in the expanded portion of the dialog box, under the **Reference Frame** tab.

To define zone motion for a moving (sliding) mesh, enable the **Mesh Motion** option in the **Fluid** dialog box. Set the appropriate parameters in the expanded portion of the dialog box, under the **Mesh Motion** tab. See Setting Up the Sliding Mesh Problem (p. 1773) for details.

For cases that do not contain zones with motion specified in a relative frame to another zone, select **absolute** from the **Relative To Cell Zone** drop-down list. Here, the velocity and rotation components are specified in an **absolute** reference frame, which is the default setting, as shown in Figure 7.12: Rotation Specified in the Absolute Reference Frame (p. 1302). If no moving zones are present in the simulation, then **absolute** will be the only available selection. See The Multiple Reference Frame Model for more information.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.12: Rotation Specified in the Absolute Reference Frame

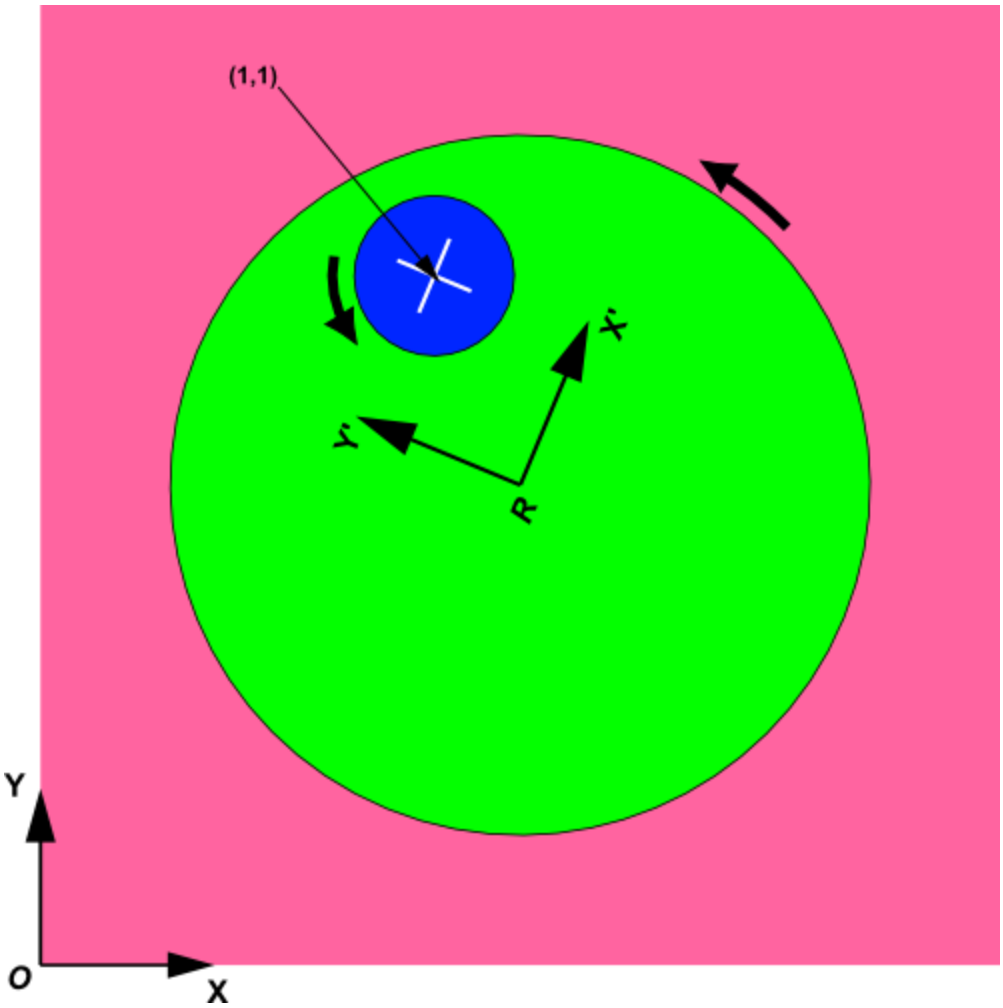


For cases where you have a moving zone specified relative to another moving zone, select the cell zone carrying the primary motion from the **Relative To Cell Zone** drop-down list under the **Reference Frame** tab or the **Mesh Motion** tab. Note that for such cases, **Rotation-Axis Origin (Relative)** will appear in the interface, signifying coordinates relative to the zone selected from the **Relative To Cell Zone** drop-down list.

Figure 7.13: Rotation Specified Relative to a Moving Zone (p. 1303) illustrates that the rotational axis origin of the small rotating zone is specified relative to the cell zone carrying the primary motion (having local coordinate system R).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.13: Rotation Specified Relative to a Moving Zone



Note:

The **Relative To Cell Zone** list will consist of all moving cell zones with an absolute motion specification (that is zones that are moving, but their motion is not relative to some other zone), excluding the current cell zone.

For problems that include linear, translational motion of the fluid zone, specify the **Translational Velocity** by setting the **X**, **Y**, and **Z** components under the **Mesh Motion** tab. For problems that include rotational motion, specify the rotational **Speed** under **Rotational Velocity**. The rotation axis is defined as described above. Note that the speed can be specified as a constant value or a transient profile. The transient profile may be in a file format, as described in Transient Cell Zone and Boundary Conditions (p. 1499), or a UDF macro (DEFINE_TRANSIENT_PROFILE). Specifying the individual velocities as either a profile or a UDF allows you to specify a single component of the frame motion individually. However, you can also specify the frame motion using a user-defined function. This may prove to be quite convenient if you are modeling a more complicated

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

motion of the moving reference frame, where the hooking of many different user-defined functions or profiles can be cumbersome.

Important:

If you need to switch between the MRF and moving mesh models, simply click the **Copy To Mesh Motion** for zones with a moving frame of reference and **Copy to Frame Motion** for zones with moving meshes to transfer motion variables, such as the axes, frame origin, and velocity components between the two models. The variables used for the origin, axis, and velocity components, as well as for the UDF `DEFINE_ZONE_MOTION` will be copied. This is particularly useful if you are doing a steady-state MRF simulation to obtain an initial solution for a transient Moving Mesh simulation in a turbomachine.

Note that when a fluid zone undergoes normal zone motion relative to an adjacent solid zone, energy transfer at that boundary (that is, the total heat transfer rate) includes pressure work when the absolute velocity formulation is used. This pressure work is on the fluid side only, not on the solid side. For details on reporting the total heat transfer rate and/or pressure work rate, see Generating a Flux Report (p. 4102).

See Modeling Flows with Moving Reference Frames (p. 1741) for details about modeling flows in moving reference frames. Details about the frame motion UDF can be found in `DEFINE_ZONE_MOTION` in the Fluent Customization Manual.

7.2.1.1.8. Defining Radiation Parameters

If you are using the DO radiation model, you can specify whether or not the fluid zone participates in radiation using the **Participates in Radiation** option. See Defining Boundary Conditions for Radiation (p. 2181) for details.

7.2.2. Solid Conditions

A "solid" zone is a group of cells for which no flow equations are solved: in a fluid simulation, only a heat conduction problem is solved; in an intrinsic fluid-structure interaction (FSI) simulation, displacement and stress tensor components are calculated. The material being treated as a solid may actually be a fluid, but it is assumed that no convection is taking place. The only required input for a solid zone is the type of solid material. You must indicate which material the solid zone contains so that the appropriate material properties will be used. Optional inputs allow you to set a volumetric heat generation rate (heat source) or a fixed value of temperature. You can also define motion for the solid zone. If there are rotationally periodic boundaries adjacent to the solid zone, you must specify the rotation axis. If you are modeling radiation using the DO model, you can specify whether or not the solid material participates in radiation.t.

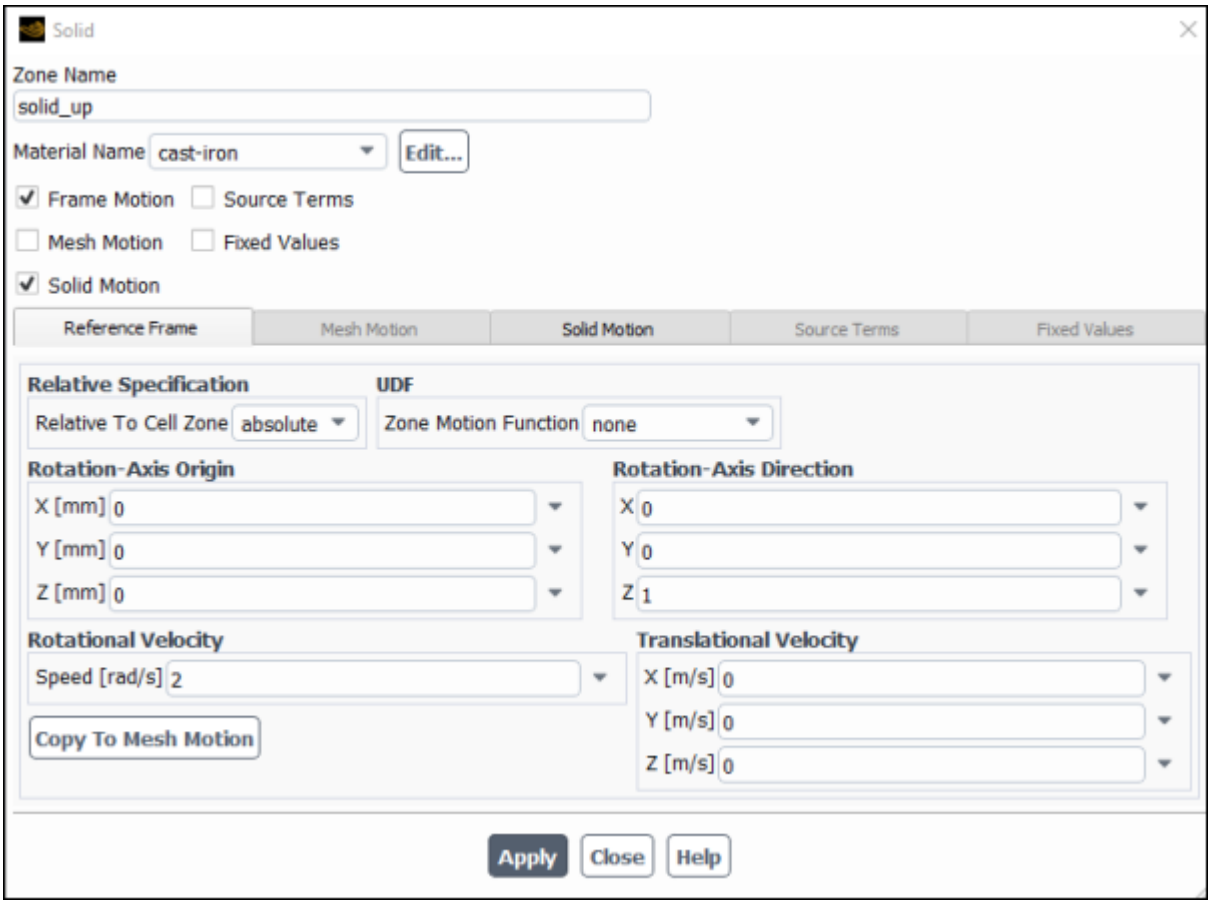
Note that the solver will always visit the active equations, including flow and possibly turbulence equations, during solver iterations. This will happen even if all the cell zones existing in the domain are solid and there is no fluid zone in the domain. In order to improve the solver performance, you may want to deactivate the flow, and turbulence equations manually when there is only solid cell zones in the domain and fluid properties are not important.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.2.2.1. Inputs for Solid Zones

You will set all solid conditions in the Solid Dialog Box (p. 4921) (Figure 7.14: The Solid Dialog Box (p. 1305)), which is opened from the **Cell Zone Conditions** task page (as described in Setting Cell Zone and Boundary Conditions (p. 1281)).

Figure 7.14: The Solid Dialog Box



7.2.2.1.1. Defining the Solid Material

To define the material contained in the solid zone, select the appropriate item in the **Material Name** drop-down list. This list will contain all solid materials database) in the Create/Edit Materials Dialog Box (p. 4833). If you want to check or modify the properties of the selected material, you can click **Edit...** to open the **Edit Material** dialog box; this dialog box contains just the properties of the selected material, not the full contents of the standard **Create/Edit Materials** dialog box.

7.2.2.1.2. Defining a Heat Source

If you want to define a source of heat within the solid zone, you can do so by enabling the **Source Terms** option. See Defining Mass, Momentum, Energy, and Other Sources (p. 1360) for details.

7.2.2.1.3. Defining a Fixed Temperature

If you want to fix the value of temperature in the solid zone, rather than computing it during the calculation, you can do so by enabling the **Fixed Values** option. See Fixing the Values of Variables (p. 1355) for details.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.2.2.1.4. Specifying the Rotation Axis for Boundary Zones

If there are rotationally periodic boundaries adjacent to the solid zone and you are not defining zone motion (as described in Defining Zone Motion (p. 1306)), you must specify the cell zone axis by defining the **Rotation-Axis Origin** and **Rotation-Axis Direction** in the **Reference Frame** tab.

The cell zone axis is independent of the axis of rotation used by any adjacent wall zones or any other cell zones. For 3D problems, the axis of rotation is the vector from the **Rotation-Axis Origin** in the direction of the vector given by your **Rotation-Axis Direction**. For 2D non-axisymmetric problems, you will specify only the **Rotation-Axis Origin**; the axis of rotation is the z -direction vector passing through the specified point. (The z direction is normal to the plane of your geometry so that rotation occurs in the plane.) For 2D axisymmetric problems, you will not define the axis: the rotation will always be about the x axis, with the origin at (0,0).

7.2.2.1.5. Defining Zone Motion

When defining motion for a solid zone, you have the following options:

- You can enable the **Frame Motion** option for a moving reference frame (MRF) simulation only If the solid zone is not moving relative to an adjacent solid zone. Then define the settings in the **Reference Frame** tab. For further details on such simulations, see Modeling Flows with Moving Reference Frames (p. 1741).
- You can enable the **Solid Motion** option If the solid zone is moving relative to an adjacent solid zone. Then define the settings in the **Solid Motion** tab.

  To complete the setup for such a simulation, you must also define the velocity boundary conditions at coupled walls between the solid zone and any adjacent fluid zones; note that this is not necessary for the walls between the solid zone and any adjacent solid zones. For the fluid zone wall, you can choose to define the wall velocity based on the solid zone motion either as an absolute velocity or relative to the adjacent fluid zone. Details about these inputs are presented in Velocity Conditions for Moving Walls (p. 1440).
- You can enable the **Mesh Motion** option for a moving (sliding) mesh, whether or not the solid zone is moving relative to an adjacent solid zone. Then define the settings in the **Mesh Motion** tab. For further details on such simulations, see Setting Up the Sliding Mesh Problem (p. 1773).

When defining the settings in the **Reference Frame** tab, **Moving Mesh** tab, and/or **Solid Mesh** tab, perform the following steps:

1. Make a selection from the **Relative To Cell Zone** drop-down list, in a manner similar to that described for fluid zones in Defining Zone Motion (p. 1301).
2. Define the **Rotation-Axis Origin** and **Rotation-Axis Direction** for the motion.

Note:

If mesh motion is specified in the same zone as frame motion and/or solid motion and this zone has rotationally periodic boundaries adjacent to it, then both axes have to be coaxial. Otherwise, the periodicity assumption is not valid and you will receive a warning message. In addition, the mesh check will fail.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The only time it is possible to have separate axes defined is when combining solid motion with frame motion. For example, you could simulate an automotive disc brake assembly where a spinning rotor that is in contact with a brake pad is modeled using solid motion, while the rotation of the assembly about the vertical axis (due to input from the steering wheel) is modeled using frame motion (see Figure 7.19: Two solids in contact where one is stationary and the other is rotating. The rotational motion of the moving solid should be described in the Solid Motion tab. Both solids may also have rotation about the y-axis described in the Frame Motion tab. (p. 1310)).

The cell zone axis is independent of the axis used by any adjacent wall zones or any other cell zones. For 3D problems, the axis is the vector from the **Rotation-Axis Origin** in the direction of the vector given by your **Rotation-Axis Direction**. For 2D non-axisymmetric problems, you will specify only the **Rotation-Axis Origin**; the axis of rotation is the z -direction vector passing through the specified point. (The z direction is normal to the plane of your geometry so that rotation occurs in the plane.) For 2D axisymmetric problems, you will not define the axis: the rotation will always be about the x axis, with the origin at (0,0).

3. For problems that include linear, translational motion of the solid zone, specify the **Translational Velocity** by setting the **X**, **Y**, and **Z** components. For problems that include rotational motion, specify the rotational **Speed** under **Rotational Velocity**. The rotation axis is defined as described above. Note that the speed can be specified as a constant value or a transient profile. The transient profile may be in a file format, as described in Transient Cell Zone and Boundary Conditions (p. 1499), or a UDF macro (`DEFINE_TRANSIENT_PROFILE`). Specifying the individual velocities as either a profile or a UDF allows you to specify a single component of the motion individually. However, you can also specify the motion using a user-defined function that uses the UDF macro `DEFINE_ZONE_MOTION`. This may prove to be quite convenient if you are modeling a more complicated motion, where the hooking of many different user-defined functions or profiles can be cumbersome.

   Important:

   Note that simultaneous translation and rotation can be modeled only if the rotation axis and the translation direction are the same (that is, the origin is fixed).

4. Note that if you decide to switch between the motion options for a solid zone, the user interface makes it easy to transfer motion variables, such as the axes, frame origin, and velocity components between the models:

   - If you need to switch from frame motion or solid motion to mesh motion, click the **Copy To Mesh Motion** button. This is particularly useful if you are doing a steady-state MRF simulation to obtain an initial solution for a transient moving mesh simulation in a turbomachine.
   - If you need to switch from mesh motion to frame motion, simply click the **Copy to Frame Motion** button.
   - If you need to switch from frame motion to solid motion, enter the following text command:

     `mesh` → `modify-zones` → `convert-all-solid-mrf-to-solid-motion`

Note that this text command applies to all solid zones with frame motion enabled. It can be useful if you are updating a frame motion simulation that was set up in a previous release before solid motion was available.

For frame motion and/or solid motion, the velocity must be divergence-free, which requires that the specified motion be tangential to the boundaries. If the motion has a normal component, the solver cannot achieve energy conservation. The only exception, for which normal motion is permitted, is a coupled wall or mesh interface between two solid zones having the same material and motion. The solver will print a warning to the solver transcript the first time it encounters a solid velocity having a significant normal component at any other boundary type. The following examples illustrate valid solid zone motion definitions:

Figure 7.15: Single Rotating Solid Zone

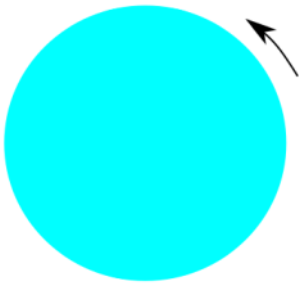


Figure 7.16: Rotating solid zone separated from another fluid or solid zone separated by a surface of revolution.

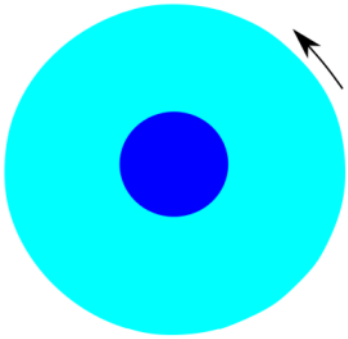

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.17: Multiple rotating solid zones having the same material and motion specifications, separated by mesh interfaces or coupled walls.

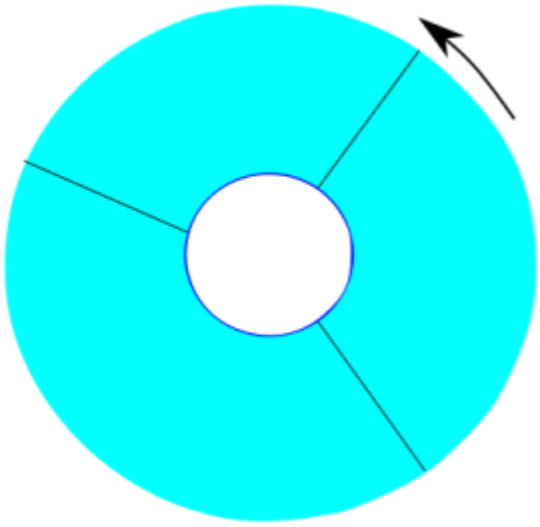

Figure 7.18: Two solids in contact where one is stationary and the other is moving with translational motion. The translational motion of the moving solid should be described in the Solid Motion tab.

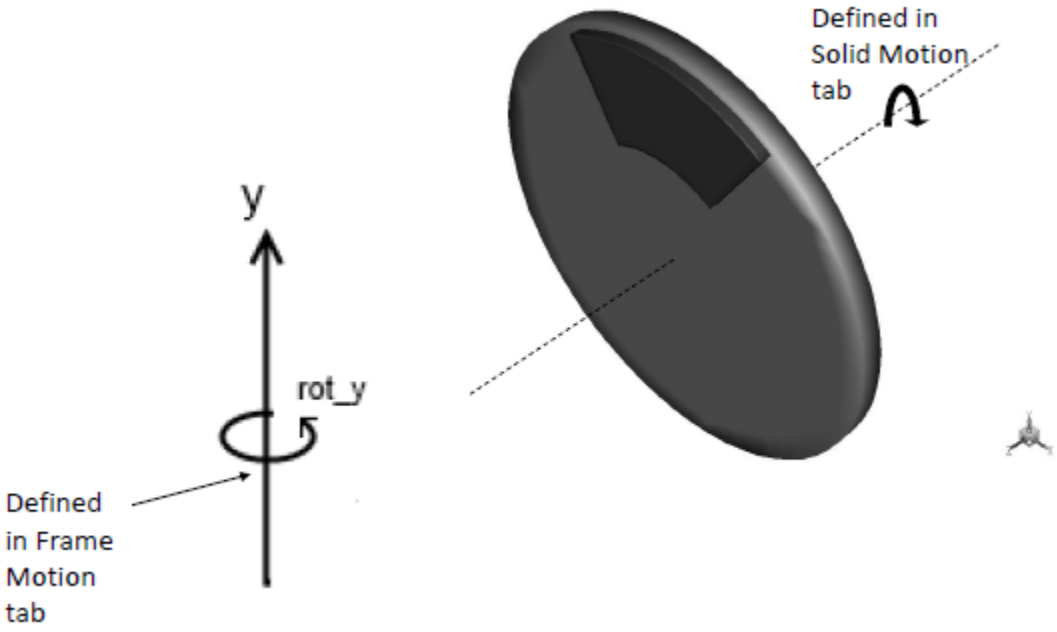
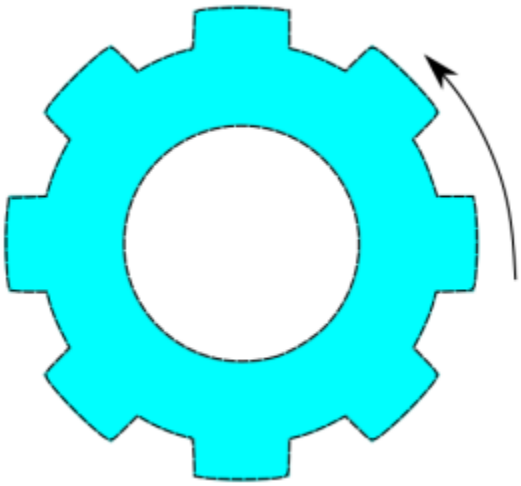
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.19: Two solids in contact where one is stationary and the other is rotating. The rotational motion of the moving solid should be described in the Solid Motion tab. Both solids may also have rotation about the y-axis described in the Frame Motion tab.



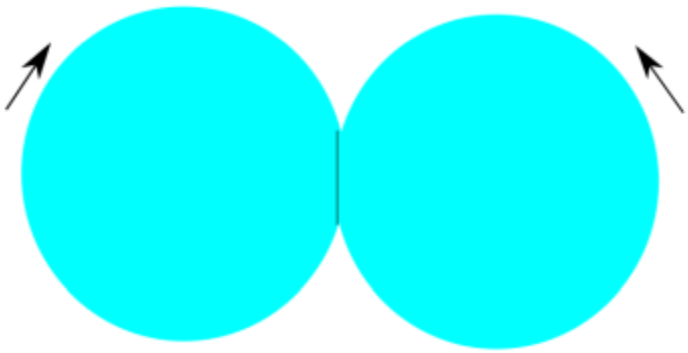
The following examples illustrate invalid frame motion or solid motion definitions for solid zones:

Figure 7.20: Rotating solid with boundaries which are not tangential to the motion.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information
of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.21: Two solids in contact with some squish. At the contact, the rotational motion has some normal component, so the solver will not achieve global energy conservation. However, the temperature field might still be acceptable for engineering purposes.



Limitations:

- The effects of motion on the solid zone are applied only to the energy equation and the structural model calculations. User-defined scalars do not include the effects of motion.
- Motion through a boundary zone adjacent to the solid zone is not permitted, though you can define a wall boundary with specified temperature condition; that is, there is no support for a 'solid inlet' or 'solid outlet'.
- The **Solid Motion** option must not be enabled in a cell zone that has dynamic smoothing and/or layering enabled.

7.2.2.1.6. Defining Radiation Parameters

If you are using the DO radiation model, you can specify whether or not the solid material participates in radiation using the **Participates in Radiation** option. See Defining Boundary Conditions for Radiation (p. 2181) for details.

7.2.3. Porous Media Conditions

The porous media model can be used for a wide variety of single phase and multiphase problems, including flow through packed beds, filter papers, perforated plates, flow distributors, and tube banks. When you use this model, you define a cell zone in which the porous media model is applied and the pressure loss in the flow is determined via your inputs as described in Momentum Equations for Porous Media (p. 1313). Heat transfer through the medium can also be represented, with or without the assumption of thermal equilibrium between the medium and the fluid flow (as described in Treatment of the Energy Equation in Porous Media (p. 1315)).

A 1D simplification of the porous media model, termed the "porous jump," can be used to model a thin membrane with known velocity/pressure-drop characteristics. The porous jump model is applied to a face zone, not to a cell zone, and should be used (instead of the full porous media model) whenever possible because it is more robust and yields better convergence. See Porous Jump Boundary Conditions (p. 1495) for details.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.2.3.1. Limitations and Assumptions of the Porous Media Model

The porous media model incorporates an empirically determined flow resistance in a region of your model defined as "porous". In essence, the porous media model adds a momentum sink in the governing momentum equations. Consequently, the following modeling assumptions and limitations should be readily recognized:

- Since the volume blockage that is physically present is not represented in the model, by default Ansys Fluent uses and reports a superficial velocity inside the porous medium, based on the volumetric flow rate, to ensure continuity of the velocity vectors across the porous medium interface. This superficial velocity formulation does not take porosity into account when calculating the convection and diffusion terms of the transport equations. You can choose to use a more accurate alternative, in which the true (physical) velocity is calculated inside the porous medium and porosity is included in the differential terms of the transport equations. See Modeling Porous Media Based on Physical Velocity (p. 1317) for details. In a multiphase flow system, all phases share the same porosity.

- The effect of the porous medium on the turbulence field is only approximated. See Treatment of Turbulence in Porous Media (p. 1317) for details.

- In general, the Ansys Fluent porous medium model, for both single phase and multiphase, assumes the porosity is isotropic, and it can vary with space and time.

- The Superficial Velocity Formulation and the Physical Velocity Formulation are available for multiphase porous media. See User Inputs for Porous Media (p. 1320) for details.

- The porous media momentum resistance and heat source terms are calculated separately on each phase. See Momentum Equations for Porous Media (p. 1313) for details.

- A unique pressure interpolation scheme is always used inside porous media zones regardless of the pressure scheme selected in the **Solution Methods** task page.

- The interactions between a porous medium and shock waves are not considered.

- When applying the porous media model in a moving reference frame, Ansys Fluent will either apply the relative reference frame or the absolute reference frame when you enable the **Relative Velocity Resistance Formulation**. This allows for the correct prediction of the source terms.

- **Standard Initialization** is the recommended initialization method for porous media simulations. The default **Hybrid Initialization** method does not account for the porous media properties, and depending on boundary conditions, may produce an unrealistic initial velocity field. For porous media simulations, the **Hybrid Initialization** method can only be used if the **Maintain Constant Velocity Magnitude** option is selected in the **Hybrid Initialization** dialog box.

- The physical velocity porous formulation may produce non-physical flow fields and poor convergence when porous resistance (Inertial or Viscous) values are less than or comparable to the change in the dynamic pressure across the porous interface (interior face zone separating the porous and non-porous cell zone). Switching the porous interface zone to a porous jump boundary is an effective way to overcome this issue.

- Solid motion is not supported in a solid zone that is coincident with a porous fluid zone that uses the non-equilibrium thermal model.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.2.3.2. Momentum Equations for Porous Media

The porous media models for single phase flows and multiphase flows use the **Superficial Velocity Porous Formulation** as the default. Ansys Fluent calculates the superficial phase or mixture velocities based on the volumetric flow rate in a porous region. The porous media model is described in the following sections for single phase flow, however, it is important to note the following for multiphase flow:

- In the Eulerian multiphase model (Eulerian Model Theory in the Theory Guide), the general porous media modeling approach, physical laws, and equations described below are applied to the corresponding phase for mass continuity, momentum, energy, and all the other scalar equations.
- The **Superficial Velocity Porous Formulation** generally gives good representations of the bulk pressure loss through a porous region. However, since the superficial velocity values within a porous region remain the same as those outside the porous region, it cannot predict the velocity increase in porous zones and therefore limits the accuracy of the model.

Porous media are modeled by the addition of a momentum source term to the standard fluid flow equations. The source term is composed of two parts: a viscous loss term (Darcy, the first term on the right-hand side of Equation 7.1 (p. 1313), and an inertial loss term (the second term on the right-hand side of Equation 7.1 (p. 1313))

$$S_i = -\left(\sum_{j=1}^{3} D_{ij} \mu v_j + \sum_{j=1}^{3} C_{ij} \frac{1}{2} \rho |v| v_j \right) \tag{7.1}$$

where S_i is the source term for the i th (x, y, or z) momentum equation, $|v|$ is the magnitude of the velocity and D and C are prescribed matrices. This momentum sink contributes to the pressure gradient in the porous cell, creating a pressure drop that is proportional to the fluid velocity (or velocity squared) in the cell.

Computation of forces on porous zones is based on viscous and inertial loss terms. The definition of these terms is in Equation 7.1 (p. 1313). Forces in simple homogenous porous media are defined in Equation 7.2 (p. 1313). Setting viscous and inertial resistance coefficients will determine the properties of the momentum sink, and subsequently the forces.

To recover the case of simple homogeneous porous media

$$S_i = -\left(\frac{\mu}{\alpha} v_i + C_2 \frac{1}{2} \rho |v| v_i \right) \tag{7.2}$$

where α is the permeability and C_2 is the inertial resistance factor, simply specify D and C as diagonal matrices with $1/\alpha$ and C_2, respectively, on the diagonals (and zero for the other elements).

Ansys Fluent also allows the source term to be modeled as a power law of the velocity magnitude:

$$S_i = -C_0 |v|^{C_1} = -C_0 |v|^{(C_1 - 1)} v_i \tag{7.3}$$

where C_0 and C_1 are user-defined empirical coefficients.

Important:

In the power-law model, the pressure drop is isotropic and the units for C_0 are SI.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.2.3.2.1. Darcy's Law in Porous Media

In laminar flows through porous media, the pressure drop is typically proportional to velocity and the constant C_2 can be considered to be zero. Ignoring convective acceleration and diffusion, the porous media model then reduces to Darcy's Law:

$$\nabla p = -\frac{\mu}{\alpha}\vec{v} \tag{7.4}$$

The pressure drop that Ansys Fluent computes in each of the three (x, y, z) coordinate directions within the porous region is then

$$\begin{aligned} \Delta p_x &= \sum_{j=1}^{3} \frac{\mu}{\alpha_{xj}} v_j \Delta n_x \\ \Delta p_y &= \sum_{j=1}^{3} \frac{\mu}{\alpha_{yj}} v_j \Delta n_y \\ \Delta p_z &= \sum_{j=1}^{3} \frac{\mu}{\alpha_{zj}} v_j \Delta n_z \end{aligned} \tag{7.5}$$

where $1/\ \alpha_{ij}$ are the entries in the matrix D in Equation 7.1 (p. 1313), v_j are the velocity components in the x, y, and z directions, and Δn_x, Δn_y, and Δn_z are the thicknesses of the medium in the x, y, and z directions.

Here, the thickness of the medium (Δn_x, Δn_y, or Δn_z) is the *actual* thickness of the porous region in your model. Therefore if the thicknesses used in your model differ from the actual thicknesses, you must make the adjustments in your inputs for $1/\ \alpha_{ij}$.

7.2.3.2.2. Inertial Losses in Porous Media

At high flow velocities, the constant C_2 in Equation 7.1 (p. 1313) provides a correction for inertial losses in the porous medium. This constant can be viewed as a loss coefficient per unit length along the flow direction, thereby allowing the pressure drop to be specified as a function of dynamic head.

If you are modeling a perforated plate or tube bank, you can sometimes eliminate the permeability term and use the inertial loss term alone, yielding the following simplified form of the porous media equation:

$$\nabla p = -\sum_{j=1}^{3} C_{2_{ij}} \left(\frac{1}{2} \rho v_j |v| \right) \tag{7.6}$$

or when written in terms of the pressure drop in the x, y, z directions:

$$\begin{aligned} \Delta p_x &\approx \sum_{j=1}^{3} C_{2_{xj}} \Delta n_x \frac{1}{2} \rho v_j |v| \\ \Delta p_y &\approx \sum_{j=1}^{3} C_{2_{yj}} \Delta n_y \frac{1}{2} \rho v_j |v| \\ \Delta p_z &\approx \sum_{j=1}^{3} C_{2_{zj}} \Delta n_z \frac{1}{2} \rho v_j |v| \end{aligned} \tag{7.7}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Again, the thickness of the medium (Δn_x, Δn_y, or Δn_z) is the thickness you have defined in your model.

7.2.3.3. Relative Viscosity in Porous Media

For viscous flows, an effective viscosity, μ_e, is introduced to account for the effect of the porous medium on the diffusion term in the momentum equations:

$$\mu_e = \mu_r \mu \tag{7.8}$$

where μ is the fluid viscosity and μ_r is the relative viscosity. In Fluent the following sub-models are implemented to calculate the relative viscosity. The effective viscosity is then calculated from Equation 7.8 (p. 1315).

Brinkman Correction [24] (p. 5656)

$$\mu_r = \left(1-\gamma\right)^{-2.5} \tag{7.9}$$

Einstein Formula [23] (p. 5656)

$$\mu_r = 1 + 2.5\left(1-\gamma\right) \tag{7.10}$$

Breugem Correlation [22] (p. 5656)

$$\mu_r = \begin{cases} \frac{1}{2}\left(\gamma - \frac{3}{7}\right) & \gamma \geq \frac{3}{7} \\ 0 & \gamma < \frac{3}{7} \end{cases} \tag{7.11}$$

7.2.3.4. Treatment of the Energy Equation in Porous Media

Ansys Fluent solves the standard energy transport equation (Equation 5.1 in the Theory Guide) in porous media regions with modifications to the conduction flux and the transient terms only.

7.2.3.4.1. Equilibrium Thermal Model Equations

For simulations in which the porous medium and fluid flow are assumed to be in thermal equilibrium, the conduction flux in the porous medium uses an effective conductivity and the transient term includes the thermal inertia of the solid region on the medium:

$$\begin{aligned} \frac{\partial}{\partial t}\left(\gamma \rho_{\mathrm{f}} E_{\mathrm{f}} + (1-\gamma)\rho_{\mathrm{s}} E_{\mathrm{s}}\right) &+ \nabla \cdot \left(\vec{v}\left(\rho_{\mathrm{f}} E_{\mathrm{f}} + p\right)\right) \\ &= S_{\mathrm{f}}^{h} + \nabla \cdot \left[k_{\mathrm{eff}} \nabla T - \left(\sum_i h_i J_i \right) + \left(\overline{\overline{\tau}} \cdot \vec{v} \right) \right] \end{aligned} \tag{7.12}$$

where

E_{f} = total fluid energy

E_{s} = total solid medium energy

ρ_{f} = fluid density

ρ_{s} = solid medium density

γ = porosity of the medium

k_{eff} = effective thermal conductivity of the medium

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

S_{f}^{h} = fluid enthalpy source term

The effective thermal conductivity in the porous medium, k_{eff}, is computed by Ansys Fluent as the volume average of the fluid conductivity and the solid conductivity:

$$k_{\mathrm{eff}}=\gamma k_{\mathrm{f}}+(1-\gamma)k_{\mathrm{s}} \tag{7.13}$$

where

k_{f} = fluid phase thermal conductivity (including the turbulent contribution, k_t)

k_{s} = solid medium thermal conductivity

The fluid thermal conductivity k_{f} and the solid thermal conductivity k_{s} can be computed via user-defined functions.

The anisotropic effective thermal conductivity can also be specified via user-defined functions. In this case, the isotropic contributions from the fluid, γk_{f}, are added to the diagonal elements of the solid anisotropic thermal conductivity matrix.

7.2.3.4.2. Non-Equilibrium Thermal Model Equations

For simulations in which the porous medium and fluid flow are not assumed to be in thermal equilibrium, a dual cell approach is used. In such an approach, a solid zone that is spatially coincident with the porous fluid zone is defined, and this solid zone only interacts with the fluid with regard to heat transfer. The conservation equations for energy are solved separately for the fluid and solid zones. The conservation equation solved for the fluid zone is

$$\frac{\partial}{\partial t}\left(\gamma\rho_{\mathrm{f}}E_{\mathrm{f}}\right)+\nabla\cdot\left(\vec{v}\left(\rho_{\mathrm{f}}E_{\mathrm{f}}+p\right)\right)=\nabla\cdot\left(\gamma k_{\mathrm{f}}\nabla T_{\mathrm{f}}-\left(\sum_{i}h_{i}J_{i}\right)+\left(\bar{\bar{\tau}}\cdot\vec{v}\right)\right)+S_{\mathrm{f}}^{h}+h_{\mathrm{fs}}A_{\mathrm{fs}}\left(T_{\mathrm{s}}-T_{\mathrm{f}}\right) \tag{7.14}$$

and the conservation equation solved for the solid zone is

$$\frac{\partial}{\partial t}\left((1-\gamma)\rho_{\mathrm{s}}E_{\mathrm{s}}\right)=\nabla\cdot\left((1-\gamma)k_{\mathrm{s}}\nabla T_{\mathrm{s}}\right)+S_{\mathrm{s}}^{h}+h_{\mathrm{fs}}A_{\mathrm{fs}}\left(T_{\mathrm{f}}-T_{\mathrm{s}}\right) \tag{7.15}$$

where

E_{f} = total fluid energy

E_{s} = total solid medium energy

ρ_{f} = fluid density

ρ_{s} = solid medium density

γ = porosity of the medium

k_{f} = fluid phase thermal conductivity (including the turbulent contribution, k_t)

k_{s} = solid medium thermal conductivity

h_{fs} = heat transfer coefficient for the fluid / solid interface

A_{fs} = interfacial area density, that is, the ratio of the area of the fluid / solid interface and the volume of the porous zone

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

T_f = temperature of the fluid

T_s = temperature of the solid medium

S_f^h = fluid enthalpy source term

S_s^h = solid enthalpy source term

The fluid thermal conductivity k_f and the solid thermal conductivity k_s can be computed via user-defined functions.

The source term due to the non-equilibrium thermal model is represented in Equation 7.14 (p. 1316) and Equation 7.15 (p. 1316) by $h_{fs}A_{fs}(T_f - T_s)$ and $h_{fs}A_{fs}(T_s - T_f)$, respectively.

7.2.3.5. Treatment of Turbulence in Porous Media

Ansys Fluent will, by default, solve the standard conservation equations for turbulence quantities in the porous medium. In this default approach, turbulence in the medium is treated as though the solid medium has no effect on the turbulence generation or dissipation rates. This assumption may be reasonable if the medium's permeability is quite large and the geometric scale of the medium does not interact with the scale of the turbulent eddies. In other instances, however, you may want to suppress the effect of turbulence in the medium.

If you are using one of the turbulence models (with the exception of the Large Eddy Simulation (LES) model), you can suppress the effect of turbulence in a porous region by enabling the **Laminar Zone** option in the Fluid Dialog Box (p. 4909). Refer to Specifying a Laminar Zone (p. 1300) for details about using the **Laminar Zone** option.

7.2.3.6. Effect of Porosity on Transient Scalar Equations

For transient porous media calculations, the effect of porosity on the time-derivative terms is accounted for in all scalar transport equations and the continuity equation. When the effect of porosity is taken into account, the time-derivative term becomes $\frac{\partial}{\partial t}(\gamma\rho\phi)$, where ϕ is the scalar quantity (k, ε, and so on) and γ is the porosity.

The effect of porosity is enabled automatically for transient calculations, and the porosity is set to 1 by default.

7.2.3.7. Modeling Porous Media Based on Physical Velocity

As stated in Limitations and Assumptions of the Porous Media Model (p. 1312), by default Ansys Fluent calculates the superficial velocity based on volumetric flow rate. The superficial velocity in the governing equations can be represented as

$$\vec{v}_{superficial} = \gamma \vec{v}_{physical} \tag{7.16}$$

where γ is the porosity of the media defined as the ratio of the volume occupied by the fluid to the total volume.

The superficial velocity values within the porous region remain the same as those outside of the porous region, and porosity is not taken into account in the differential terms of the transport equations. This limits the accuracy of the porous model in cases where there should be an increase

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

in velocity throughout the porous region, and does not yield accurate results when velocity values and gradients are important. For more accurate simulations of porous media flows, it becomes necessary to solve for the true, or physical, velocity throughout the flowfield rather than the superficial velocity, as well as to include porosity in all terms of the transport equations.

Ansys Fluent allows the calculation of the physical velocity using the **Porous Formulation**, available in the **Cell Zone Conditions** task page. By default, the **Superficial Velocity** option is turned on.

7.2.3.7.1. Single Phase Porous Media

Using the physical velocity formulation, and assuming a general scalar ϕ, the governing equation in an isotropic porous media has the following form:

$$\frac{\partial(\gamma\rho\phi)}{\partial t}+\nabla\cdot(\gamma\rho\vec{v}\phi)=\nabla\cdot(\gamma\Gamma\nabla\phi)+S_{\phi} \tag{7.17}$$

Assuming isotropic porosity and single phase flow, the volume-averaged mass and momentum conservation equations are as follows:

$$\frac{\partial(\gamma\rho)}{\partial t}+\nabla\cdot(\gamma\rho\vec{v})=0 \tag{7.18}$$

$$\frac{\partial(\gamma\rho\vec{v})}{\partial t}+\nabla\cdot(\gamma\rho\vec{v}\vec{v})=-\gamma\nabla p+\nabla\cdot(\gamma\vec{\tau})+\gamma\vec{B}_f-\left(\frac{\gamma^2\mu}{K}\vec{v}+\frac{\gamma^3 C_2}{2}\rho|\vec{v}|\vec{v}\right) \tag{7.19}$$

The last term in Equation 7.19 (p. 1318) represents the viscous and inertial drag forces imposed by the pore walls on the fluid.

Important:

Note that even when you solve for the physical velocity in Equation 7.19 (p. 1318), the two resistance coefficients can still be derived using the superficial velocity as given in Defining the Viscous and Inertial Resistance Coefficients (p. 1324). Ansys Fluent assumes that the inputs for these resistance coefficients are based upon well-established empirical correlations that are usually based on superficial velocity. Therefore, Ansys Fluent automatically converts the inputs for the resistance coefficients into those that are compatible with the physical velocity formulation.

Important:

Note that the inlet mass flow is also calculated from the superficial velocity. Therefore, for the same mass flow rate at the inlet and the same resistance coefficients, for either the physical or superficial velocity formulation you should obtain the same pressure drop across the porous media zone.

Important:

The effect of porosity is not applied in Ansys Fluent's treatment of user defined sources. If porosity effects need to be included, they should be incorporated in the definition of the source terms. This applies to all user defined sources in Ansys Fluent.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.2.3.7.2. Multiphase Porous Media

You can simulate porous media multiphase flows using the **Physical Velocity Porous Formulation** to solve the true or physical velocity field throughout the entire flow field, including both porous and non-porous regions. In this approach, assuming a general scalar in the q^{th} phase, ϕ_q, the governing equation in an isotropic porous medium takes on the following form:

$$\frac{\partial\left(\gamma\alpha_q\rho_q\phi_q\right)}{\partial t}+\nabla\cdot\left(\gamma\alpha_q\rho_q\vec{v}_q\phi_q\right)=\nabla\cdot\left(\gamma\Gamma_q\nabla\phi_q\right)+S_{\phi,q} \tag{7.20}$$

Here γ is the porosity, which may vary with time and space; ρ_q is the phase density; α_q is the volume fraction; $\vec{v}_q$ is the phase velocity vector; $S_{\phi,q}$ is the source term; and Γ_q is the diffusion coefficient.

Important:

The effect of porosity is not applied in Ansys Fluent's treatment of user defined sources. If porosity effects need to be included, they should be incorporated in the definition of the source terms. This applies to all user defined sources in Ansys Fluent.

The general scalar equation Equation 7.20 (p. 1319) applies to all other transport equations in the Eulerian multiphase model, such as the granular phase momentum and energy equations, turbulence modeling equations, and the species transport equations.

Assuming isotropic porosity and multiphase flows, the governing equations in the q^{th} phase, Equation 14.193, Equation 14.194, and Equation 14.197 in the Theory Guide take the general forms described below.

7.2.3.7.2.1. The Continuity Equation

$$\frac{\partial}{\partial t}\left(\gamma\alpha_q\rho_q\right)+\nabla\cdot\left(\gamma\alpha_q\rho_q\vec{v}_q\right)=\gamma\sum_{\substack{p=1\\p\neq q}}^{n}\left(\dot{m}_{pq}-\dot{m}_{qp}\right)+S_q \tag{7.21}$$

7.2.3.7.2.2. The Momentum Equation

$$\begin{aligned}\frac{\partial}{\partial t}\left(\gamma\alpha_q\rho_q\vec{v}_q\right)+\nabla\cdot\left(\gamma\alpha_q\rho_q\vec{v}_q\vec{v}_q\right)= \; & -\gamma\alpha_q\nabla\left(p-p_c\right)+\nabla\cdot\left(\gamma\bar{\bar{\tau}}_q\right)+\gamma\alpha_q\rho_q\vec{B}_f \\ & -\left(\alpha_q^2\gamma^2\frac{\mu_q\vec{v}_q}{KK_{r,q}}+\alpha_q^3\gamma^3\frac{C_2\rho_q|\vec{v}_q|\vec{v}_q}{2}\right) \\ & +\gamma\sum_{p=1}^{n}\left(\vec{F}_{pq}^{\,D}+\vec{F}_{pq}^{\,TD}+\dot{m}_{pq}\vec{v}_{pq}-\dot{m}_{qp}\vec{v}_{qp}\right) \\ & +\gamma\left(\vec{F}_q+\vec{F}_q^{\,L}+\vec{F}_q^{\,vm}\right)\end{aligned} \tag{7.22}$$

where p_c is capillary pressure for the wetting phase, $\bar{\bar{\tau}}_q$ is phase shear stress, $\vec{B}_f$ is the body force, $\dot{m}_{pq}$ and $\dot{m}_{qp}$ are the mass transfers from phase p to phase q and vice versa, K is the absolute permeability, and $K_{r,q}$ is the relative permeability. The term in the brackets is the porous sink, having zero value in non-porous flows/regions. The last two terms includes the

general interphase momentum exchange forces: $\vec{F}_{pq}^{D}$ is the drag force for non-porous flows/regions, $\vec{F}_{pq}^{TD}$ is the turbulent dispersed force, $\vec{v}_{pq}$ and $\vec{v}_{qp}$ are the relative velocity vectors, and $\vec{F}_q$, $\vec{F}_q^{L}$, and $\vec{F}_q^{vm}$ are the external body, lift and virtual mass exchange forces. If the capillary pressure model is not enabled, $K_{r,q}$ =1.

Details about the user inputs related to the momentum resistance sources can be found in User Inputs for Porous Media (p. 1320).

7.2.3.7.2.3. The Energy Equation

$$\frac{\partial}{\partial t}\left(\alpha_q\left(\gamma\rho_q h_q+\left(1-\gamma\right)\rho_s h_s\right)\right)+\nabla\cdot\left(\gamma\alpha_q\rho_q\vec{v}_q h_q\right)= -\gamma\alpha_q\frac{\partial p_q}{\partial t}+\gamma\bar{\bar{\tau}}_q:\nabla\vec{v}_q-\nabla\cdot\left(\alpha_q\left(\gamma k_q+\left(1-\gamma\right)k_s\right)\nabla T_q\right) +S_q+\gamma\sum_n^{p=1}\left(Q_{pq}+\dot{m}_{pq}h_{pq}-\dot{m}_{qp}h_{qp}\right) \tag{7.23}$$

where:

Subscripts q, p, and s denote phase q, phase p, and the solid material, respectively

h is the total enthalpy

k is the thermal conductivity

Q_{pq} is the heat transfer between phase p and phase q

ρ is the density

S is the heat source

α is the phase volume fraction

$\vec{v}$ is the phase velocity

h_{pq} and h_{qp} are the total enthalpy differences between phases p and q and vice versa

7.2.3.8. User Inputs for Porous Media

When you are modeling a porous region, the additional inputs for the problem setup are as follows. Optional inputs are indicated as such.

1. Define the porous zone (as described in Defining the Porous Zone (p. 1322)).
2. (optional) Define the porous velocity formulation in the **Cell Zone Conditions** task page (as described in Defining the Porous Velocity Formulation (p. 1322)).
3. Identify the fluid material flowing through the porous medium (as described in Defining the Fluid Passing Through the Porous Medium (p. 1323)).
4. Enable reactions for the porous zone, if appropriate, and select the reaction mechanism (as described in Enabling Reactions in a Porous Zone (p. 1323)).
5. Enable the **Relative Velocity Resistance Formulation**. By default, this option is already enabled and takes the moving porous media into consideration (as described in Including the Relative Velocity Resistance Formulation (p. 1323)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. Set the viscous resistance coefficients (D_{ij} in Equation 7.1 (p. 1313), or $1/\alpha$ in Equation 7.2 (p. 1313)) and the inertial resistance coefficients (C_{ij} in Equation 7.1 (p. 1313), or C_2 in Equation 7.2 (p. 1313)), and define the direction vectors for which they apply. Alternatively, specify the coefficients for the power-law model. (See Defining the Viscous and Inertial Resistance Coefficients (p. 1324) for more details.)

7. Specify the porosity of the porous medium (as described in Defining Porosity (p. 1332)).

8. (optional) Specify the settings for heat transfer (as described in Specifying the Heat Transfer Settings (p. 1332)).

9. (optional) Specify a model for relative viscosity (as described in Specifying the Relative Viscosity (p. 1336)).

10. (optional, Eulerian multiphase models only) Specify relative permeability (as described in Specifying the Relative Permeability (p. 1336).

11. (optional) Set the volumetric heat generation rates in the porous medium (or any other sources, such as mass or momentum). (See Defining Sources (p. 1348) for more details.)

12. (optional) Set any fixed values for solution variables in the fluid region (as described in Defining Fixed Values (p. 1348).

13. Suppress the turbulent viscosity in the porous region, if appropriate. (See Suppressing the Turbulent Viscosity in the Porous Region (p. 1348) for more details.)

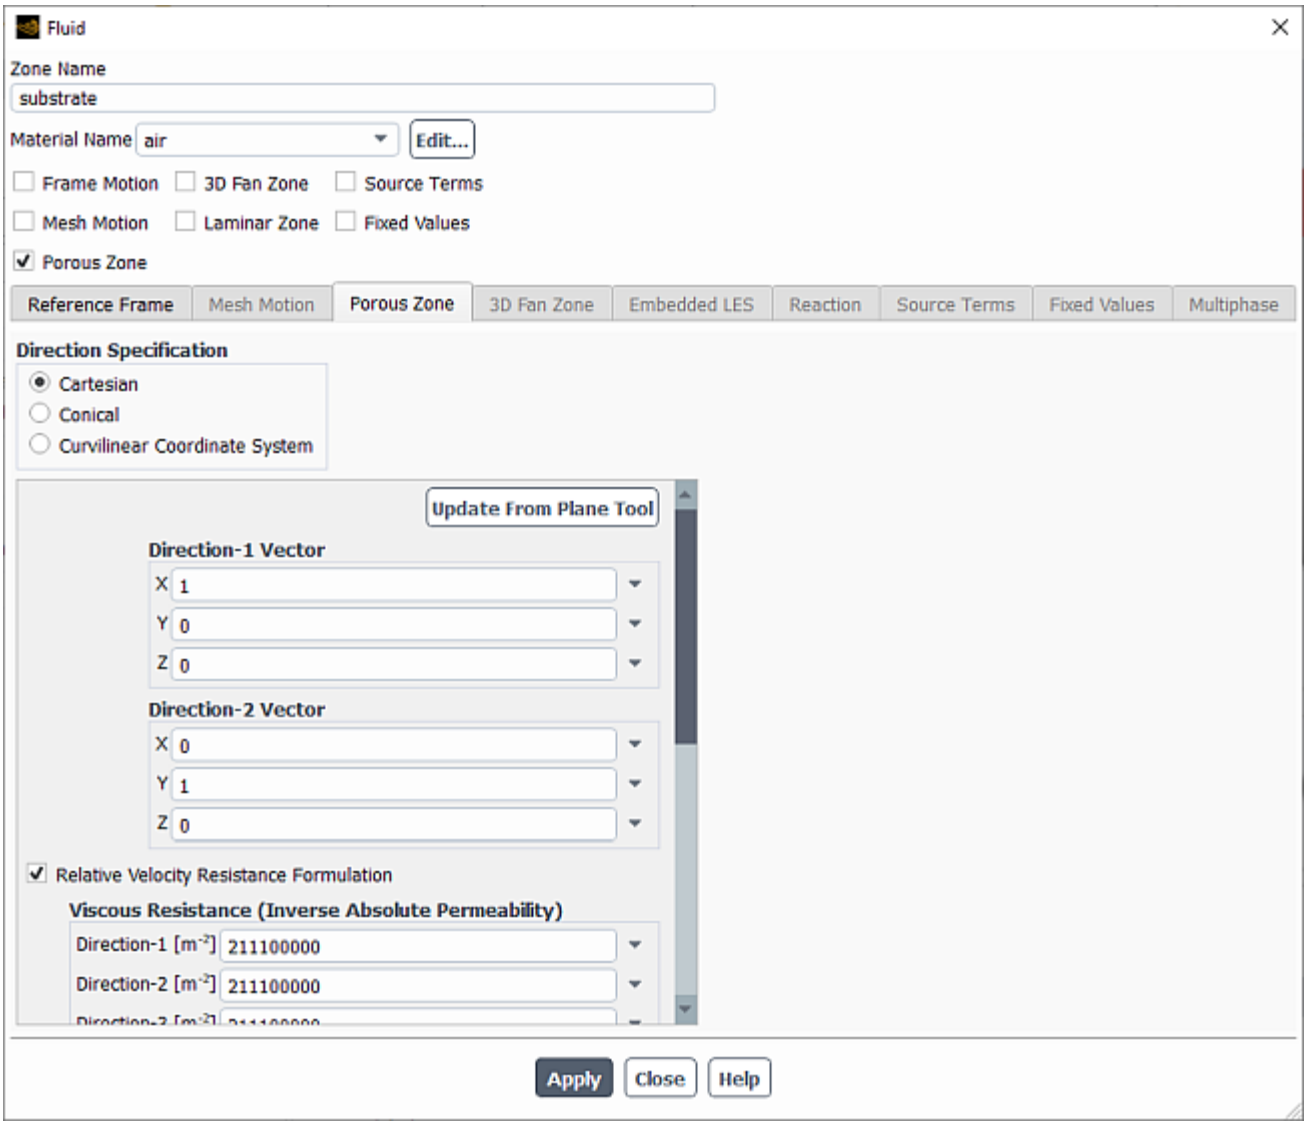
14. Specify the rotation axis and/or zone motion, if relevant. (See Specifying the Rotation Axis and Defining Zone Motion (p. 1348) for more details.)

Methods for determining the resistance coefficients and/or permeability are presented below. If you choose to use the power-law approximation of the porous-media momentum source term, you will enter the coefficients C_0 and C_1 in Equation 7.3 (p. 1313) instead of the resistance coefficients and flow direction.

You will set all parameters for the porous medium in the Fluid Dialog Box (p. 4909) (Figure 7.22: The Fluid Dialog Box for a Porous Zone (p. 1322)), which is opened from the **Cell Zone Conditions** task page (as described in Setting Cell Zone and Boundary Conditions (p. 1281)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.22: The Fluid Dialog Box for a Porous Zone



7.2.3.8.1. Defining the Porous Zone

As mentioned in Overview (p. 1277), a porous zone is modeled as a special type of fluid zone. To indicate that the fluid zone is a porous region, enable the **Porous Zone** option in the **Fluid** dialog box. The dialog box will expand to show the porous media inputs (as shown in Figure 7.22: The Fluid Dialog Box for a Porous Zone (p. 1322)).

In a coupled analysis involving Fluent and System Coupling, a porous jump boundary of zero-thickness next to the porous zone can be used to transfer data between the porous zone and the System Coupling system. For more about System Coupling and the variable transferred from a porous jump boundary, see Performing System Coupling Simulations Using Fluent (p. 4595).

7.2.3.8.2. Defining the Porous Velocity Formulation

The **Cell Zone Conditions** task page contains a **Porous Formulation** region where you can instruct Ansys Fluent to use either a superficial or physical velocity in the porous medium simulation. By

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

default, the velocity is set to **Superficial Velocity**. For details about using the **Physical Velocity** formulation, see Modeling Porous Media Based on Physical Velocity (p. 1317).

7.2.3.8.3. Defining the Fluid Passing Through the Porous Medium

To define the fluid that passes through the porous medium, select the appropriate fluid in the **Material Name** drop-down list in the Fluid Dialog Box (p. 4909). If you want to check or modify the properties of the selected material, you can click **Edit...** to open the **Edit Material** dialog box; this dialog box contains just the properties of the selected material, not the full contents of the standard **Create/Edit Materials** dialog box.

Important:

If you are modeling species transport or multiphase flow, the **Material Name** list will not appear in the **Fluid** dialog box. For species calculations, the mixture material for all fluid/porous zones will be the material you specified in the Species Model Dialog Box (p. 4716). For multiphase flows, the materials are specified when you define the phases, as described in Defining the Phases for the VOF Model (p. 3005).

7.2.3.8.4. Enabling Reactions in a Porous Zone

If you are modeling species transport with reactions, you can enable reactions in a porous zone by turning on the **Reaction** option in the **Fluid** dialog box and selecting a mechanism in the **Reaction Mechanism** drop-down list.

If your mechanism contains wall surface reactions, you also must specify a value for the **Surface-to-Volume Ratio**. This value is the surface area of the pore walls per unit volume ($\frac{A}{V}$), and can be thought of as a measure of catalyst loading. With this value, Ansys Fluent can calculate the total surface area on which the reaction takes place in each cell by multiplying $\frac{A}{V}$ by the volume of the cell and the porosity. See Defining Zone-Based Reaction Mechanisms (p. 2385) for details about defining reaction mechanisms. See Wall Surface Reactions and Chemical Vapor Deposition (p. 2397) for details about wall surface reactions.

Note:

The wall surface reactions in porous medium are allowed only for the pressure-based solver.

7.2.3.8.5. Including the Relative Velocity Resistance Formulation

For cases involving moving meshes, dynamic meshes or moving reference frames (MRF), the **Relative Velocity Resistance Formulation** option allows you to better predict porous media sources. The porous media source terms are calculated using relative velocities in the porous zone. For more information, see Momentum Equations for Porous Media (p. 1313). The **Relative Velocity Resistance Formulation** option works well for cases with moving and stationary porous media. It is turned on by default.

Note the following limitation when using the **Relative Velocity Resistance Formulation** option:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The relative velocity resistance formulation is not supported with axisymmetric-swirl when there are non-zero swirl resistances.

Note:

In Ansys Fluent 6.3, this option was only supported for moving mesh and MRF (with the exception of power law for modeling porous sources). Currently, this option also supports dynamic mesh and takes care of proper treatment of porous sources using power law.

7.2.3.8.6. Defining the Viscous and Inertial Resistance Coefficients

The viscous and inertial resistance coefficients are both defined in the same manner. The basic approach for defining the coefficients using a Cartesian coordinate system is to define one direction vector (**Direction-1 Vector**) in 2D or two direction vectors (**Direction-1 Vector** and **Direction-2 Vector**) in 3D, and then specify the viscous and/or inertial resistance coefficients in each direction. The **Direction-1 Vector** usually represents the primary flow direction (parallel to the porous zone axis), and the other two directions represent the transverse directions.

Ansys Fluent automatically determines the second direction vector in 2D or the third direction vector in 3D, which is not explicitly defined:

- In 2D, the second direction is normal to the plane defined by the **Direction-1 Vector** and the z-direction vector.
- In 3D, the third direction is normal to the plane defined by the **Direction-1 Vector** and **Direction-2 Vector**. Note that the **Direction-2 Vector** must be normal to the **Direction-1 Vector**. If you fail to specify two normal directions, the Ansys Fluent solver will orthogonalize the direction specification by removing the projection of the **Direction-2 Vector** on the **Direction-1 Vector** before computing the third mutually orthogonal direction. You should therefore be certain that the first direction is correctly specified.

If the porous zone faces are not aligned with the global Cartesian axis, you can use the plane tool in 3D or the line tool in 2D for the direction vector definitions as further described.

You can also define the viscous and/or inertial resistance coefficients in each direction using a user-defined function (UDF). The user-defined options become available in the corresponding drop-down list when the UDF has been created and loaded into Ansys Fluent. Note that the coefficients defined in the UDF must utilize the `DEFINE_PROFILE` macro. For more information on creating and using user-defined function, see the Fluent Customization Manual.

If you are modeling axisymmetric swirling flows, you can specify an additional direction component for the viscous and/or inertial resistance coefficients. This direction component is always tangential to the other two specified directions. This option is available for both density-based and pressure-based solvers.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In 3D, it is also possible to define the coefficients using a conical (or cylindrical) coordinate system, as described below.

Important:

Note that the viscous and inertial resistance coefficients are generally based on the superficial velocity of the fluid in the porous media.

The procedure for defining resistance coefficients is as follows:

1. Define the direction vectors.

   - To use a Cartesian coordinate system, simply specify the **Direction-1 Vector** and, for 3D, the **Direction-2 Vector**. The unspecified direction will be determined as described above. These direction vectors correspond to the principle axes of the porous media.

     Note:

     The units for the inertial resistance coefficients (**Direction-1 Vector** and **Direction-2 Vector**) is the inverse of length. Should you want to define different units, you can do so by opening the **Units** dialog box and selecting **resistance** from the **Quantities** list.

     For some problems in which the principal axes of the porous medium are not aligned with the coordinate axes of the domain, you may not know a priori the direction vectors of the porous medium. In such cases, the plane tool (available via the **Plane Surface** dialog box) in 3D or the line tool (available via the **Line/Rake Surface** dialog box) in 2D can help you to determine these direction vectors.

     a. Open the **Plane Surface** dialog box in 3D or the **Line/Rake Surface** dialog box in 2D to enable the plane or line tool.

     b. Rotate the axes of the tool appropriately until they are aligned with the porous medium. You may want to move the plane tool (or the line tool) onto the boundary of the porous region. (Follow the instructions in Using the Plane Tool (p. 3813) or Using the Line Tool (p. 3808) for initializing the tool to a position on an existing surface.)

     c. Once the axes are aligned, click the **Update From Plane Tool** or **Update From Line Tool** button in the **Fluid** dialog box. Ansys Fluent will automatically set the **Direction-1 Vector** to the direction of the red arrow of the tool, and (in 3D) the **Direction-2 Vector** to the direction of the green arrow.

     Important:

     The Plane Surface Dialog Box (p. 5523) or the Line/Rake Surface Dialog Box (p. 5458) must be open for the plane or line tool to be active.

   - To use a conical coordinate system (for example, for an annular, conical filter element), follow the steps below. This option is available only in 3D cases.

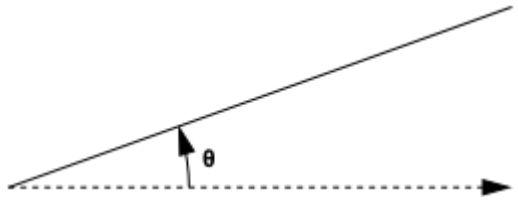
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

a. Turn on the **Conical** option.

b. Set the **Cone Half Angle** (the angle between the cone's axis and its surface, shown in Figure 7.23: Cone Half Angle (p. 1326)). To use a cylindrical coordinate system, set the **Cone Half Angle** to 0.

c. Specify the **Cone Axis Vector** and **Point on Cone Axis**. The cone axis is specified as being in the direction of the **Cone Axis Vector** (unit vector), and passing through the **Point on Cone Axis**. The cone axis may or may not pass through the origin of the coordinate system.

Figure 7.23: Cone Half Angle



For some problems in which the axis of the conical filter element is not aligned with the coordinate axes of the domain, you may not know a priori the direction vector of the cone axis and coordinates of a point on the cone axis. In such cases, the plane tool can help you to determine the cone axis vector and point coordinates. One method is as follows:

a. Select a boundary zone of the conical filter element that is normal to the cone axis vector in the drop-down list next to the **Snap to Zone** button.

b. Click the **Snap to Zone** button. Ansys Fluent will automatically "snap" the plane tool onto the boundary. It will also set the **Cone Axis Vector** and the **Point on Cone Axis**. (Note that you will still have to set the **Cone Half Angle** yourself.)

An alternate method is as follows:

a. Move the plane tool onto the boundary of the porous region. (Follow the instructions in Using the Plane Tool (p. 3813) for moving the tool to a position on an existing surface.) *Open the **Plane Surface** dialog box to enable the plane tool.*

b. Rotate and translate the axes of the tool appropriately until the red arrow of the tool is pointing in the direction of the cone axis vector and the origin of the tool is on the cone axis.

c. Once the axes and origin of the tool are aligned, click the **Update From Plane Tool** button in the **Fluid** dialog box. Ansys Fluent will automatically set the **Cone Axis Vector** and the **Point on Cone Axis**. (Note that you will still have to set the **Cone Half Angle** yourself.)

Open the Plane Surface Dialog Box (p. 5523) or the Line/Rake Surface Dialog Box (p. 5458) to make the plane or line tool appear.

- To use a curvilinear coordinate system (such as for a winding or coil), follow the steps below. This option is available only in 3D cases.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

a. Under **Direction Specification**, select **Curvilinear Coordinate System**.

b. For **Coordinate System**, select an already created curvilinear coordinate system or you can create a new one by clicking **New...**. For details on creating a curvilinear coordinate system, see Curvilinear Coordinate Systems (p. 1143).

c. For **Viscous Resistance** and **Inertial Resistance**, the direction components will correspond to the directions defined for the chosen curvilinear coordinate system.

2. Under **Viscous Resistance**, specify the viscous resistance coefficient $1/\alpha$ in each direction.

   Under **Inertial Resistance**, specify the inertial resistance coefficient C_2 in each direction. (You can scroll down with the scroll bar to view these inputs.)

   For porous media cases containing highly anisotropic inertial resistances, enable **Alternative Formulation** under **Inertial Resistance**. The **Alternative Formulation** option provides better stability to the calculation when your porous medium is anisotropic. The pressure loss through the medium depends on the magnitude of the velocity vector of the i th component in the medium. Using the formulation of Equation 7.6 (p. 1314) yields the expression below:

$$S_i = \frac{1}{2}\rho C_i |v_i| v_i \tag{7.24}$$

   Whether or not you use the **Alternative Formulation** option depends on how well you can fit your experimentally determined pressure drop data to the Ansys Fluent model. For example, if the flow through the medium is aligned with the mesh in your Ansys Fluent model, then it will not make a difference whether or not you use the formulation. In general, however, the default and the **Alternative Formulation** are not equivalent, and solution differences can occur when switching between the two options.

   Note:

   After you change the status of the **Alternative Formulation** option, you need to rerun the simulation to obtain consistent force reports and cumulative plots (Cumulative Force, Moment, and Coefficients Plots (p. 4061)) for lift, drag, moments, and corresponding coefficients computed on porous zones. This is because the porous force contribution is always obtained on demand by recomputing the porous sources used in the momentum equations, which can change with enabling or disabling the **Alternative Formulation** option.

   For more information about simulations involving highly anisotropic porous media, see Solution Strategies for Porous Media (p. 1349).

   Important:

   Note that the alternative formulation is compatible only with the pressure-based solver.

   If you are using the **Conical** specification method, **Direction-1** is the tangential direction of the cone, **Direction-2** is the normal to the cone surface (radial (r) direction for a cylinder), and **Direction-3** is the circumferential (θ) direction.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In 3D there are three possible categories of coefficients, and in 2D there are two:

- In the isotropic case, the resistance coefficients in all directions are the same (for example, a sponge). For an isotropic case, you must explicitly set the resistance coefficients in each direction to the same value.
- When (in 3D) the coefficients in two directions are the same and those in the third direction are different or (in 2D) the coefficients in the two directions are different, you must be careful to specify the coefficients properly for each direction. For example, if you had a porous region consisting of cylindrical straws with small holes in them positioned parallel to the flow direction, the flow would pass easily through the straws, but the flow in the other two directions (through the small holes) would be very little. If you had a plane of flat plates perpendicular to the flow direction, the flow would not pass through them at all; it would instead move in the other two directions.
- In 3D the third possible case is one in which all three coefficients are different. For example, if the porous region consisted of a plane of irregularly-spaced objects (for example, pins), the movement of flow between the blockages would be different in each direction. You would therefore need to specify different coefficients in each direction.

Methods for deriving viscous and inertial loss coefficients are described in the sections that follow.

7.2.3.8.7. Deriving Porous Media Inputs Based on Superficial Velocity, Using a Known Pressure Loss

When you use the porous media model, you must remember that the porous cells in Ansys Fluent are *100% open*, and that the values that you specify for $1/\ \alpha_{ij}$ and/or $C_{2_{ij}}$ must be based on this assumption. Suppose, however, that you know how the pressure drop varies with the velocity through the actual device, which is only partially open to flow. The following exercise is designed to show you how to compute a value for C_2 which is appropriate for the Ansys Fluent model.

Consider a perforated plate that has 25% area open to flow. The pressure drop through the plate is known to be 0.5 times the dynamic head in the plate. The loss factor, K_L, defined as

$$\Delta p = K_L\left(\frac{1}{2}\rho v^2_{25\%open}\right) \tag{7.25}$$

is therefore 0.5, based on the actual fluid velocity in the plate, that is, the velocity through the 25% open area. To compute an appropriate value for C_2, note that in the Ansys Fluent model:

1. The velocity through the perforated plate assumes that the plate is 100% open.
2. The loss coefficient must be converted into dynamic head loss per unit length of the porous region.

Noting item 1, the first step is to compute an adjusted loss factor, $K_L^{'}$, which would be based on the velocity of a 100% open area:

$$\Delta p = K_L^{'}\left(\frac{1}{2}\rho v^2_{100\%open}\right) \tag{7.26}$$

or, noting that for the same flow rate, $v_{25\%open} = 4 \times v_{100\%open}$,

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$K'_L = K_L \times \frac{v^2_{25\%open}}{v^2_{100\%open}} = 0.5 \times \left(\frac{4}{1}\right)^2 = 8 \tag{7.27}$$

The adjusted loss factor has a value of 8. Noting item 2, you must now convert this into a loss coefficient per unit thickness of the perforated plate. Assume that the plate has a thickness of 1.0 mm (10^{-3} m). The inertial loss factor would then be

$$C_2 = \frac{K_{K'_L}}{thickness} = \frac{8}{10^{-3}} = 8000 m^{-1} \tag{7.28}$$

Note that, for anisotropic media, this information must be computed for each of the 2 (or 3) coordinate directions.

7.2.3.8.8. Using the Ergun Equation to Derive Porous Media Inputs for a Packed Bed

As a second example, consider the modeling of a packed bed. In turbulent flows, packed beds are modeled using both a permeability and an inertial loss coefficient. One technique for deriving the appropriate constants involves the use of the Ergun equation [40] (p. 5657), a semi-empirical correlation applicable over a wide range of Reynolds numbers and for many types of packing:

$$\frac{|\Delta p|}{L} = \frac{150\mu}{D_p^2}\frac{\left(1-\varepsilon\right)^2}{\varepsilon^3} v_\infty + \frac{1.75\rho}{D_p}\frac{\left(1-\varepsilon\right)}{\varepsilon^3} v_\infty^2 \tag{7.29}$$

When modeling laminar flow through a packed bed, the second term in the above equation may be dropped, resulting in the Blake-Kozeny equation [40] (p. 5657):

$$\frac{|\Delta p|}{L} = \frac{150\mu}{D_p^2}\frac{\left(1-\varepsilon\right)^2}{\varepsilon^3} v_\infty \tag{7.30}$$

In these equations, μ is the viscosity, D_p is the mean particle diameter, L is the bed depth, and ε is the void fraction, defined as the volume of voids divided by the volume of the packed bed region. Comparing Equation 7.4 (p. 1314) and Equation 7.6 (p. 1314) with Equation 7.29 (p. 1329), the permeability and inertial loss coefficient in each component direction may be identified as

$$\alpha = \frac{D_p^2}{150}\frac{\varepsilon^3}{\left(1-\varepsilon\right)^2} \tag{7.31}$$

and

$$C_2 = \frac{3.5}{D_p}\frac{\left(1-\varepsilon\right)}{\varepsilon^3} \tag{7.32}$$

7.2.3.8.9. Using an Empirical Equation to Derive Porous Media Inputs for Turbulent Flow Through a Perforated Plate

As a third example we will take the equation of Van Winkle et al. [114] (p. 5661) [145] (p. 5663) and show how porous media inputs can be calculated for pressure loss through a perforated plate with square-edged holes.

The expression, which is claimed by the authors to apply for turbulent flow through square-edged holes on an equilateral triangular spacing, is

$$\dot{m}=CA_f\sqrt{\left(2\rho\Delta p\right)/\left(1-\left(A_f/A_p\right)^2\right)} \tag{7.33}$$

where

$\dot{m}$ = mass flow rate through the plate

A_f = the free area or total area of the holes

A_p = the area of the plate (solid and holes)

C = a coefficient that has been tabulated for various Reynolds-number ranges and for various D/t

D/t = the ratio of hole diameter to plate thickness

for $t/D>1.6$ and for $Re>4000$ the coefficient C takes a value of approximately 0.98, where the Reynolds number is based on hole diameter and velocity in the holes.

Rearranging Equation 7.33 (p. 1330), making use of the relationship

$$\dot{m}=\rho v A_p \tag{7.34}$$

and dividing by the plate thickness, $\Delta x=t$, we obtain

$$\frac{\Delta p}{\Delta x}=\left(\frac{1}{2}\rho v^2\right)\frac{1}{C^2}\frac{\left(A_p/A_f\right)^2-1}{t} \tag{7.35}$$

where v is the superficial velocity (not the velocity in the holes). Comparing with Equation 7.6 (p. 1314) is seen that, for the direction normal to the plate, the constant C_2 can be calculated from

$$C_2=\frac{1}{C^2}\frac{\left(A_p/A_f\right)^2-1}{t} \tag{7.36}$$

7.2.3.8.10. Using Tabulated Data to Derive Porous Media Inputs for Laminar Flow Through a Fibrous Mat

Consider the problem of laminar flow through a mat or filter pad which is made up of randomly-oriented fibers of glass wool. As an alternative to the Blake-Kozeny equation (Equation 7.30 (p. 1329)) we might choose to employ tabulated experimental data. Such data is available for many types of fiber [68] (p. 5659).

Volume Fraction of Solid Material	Dimensionless Permeability B of Glass Wool
0.262	0.25
0.258	0.26
0.221	0.40
0.218	0.41
0.172	0.80

where $B=\alpha/a^2$ and a is the fiber diameter. α, for use in Equation 7.4 (p. 1314), is easily computed for a given fiber diameter and volume fraction.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.2.3.8.11. Deriving the Porous Coefficients Based on Experimental Pressure and Velocity Data

Experimental data that is available in the form of pressure drop against velocity through the porous component, can be extrapolated to determine the coefficients for the porous media. To effect a pressure drop across a porous medium of thickness, Δn, the coefficients of the porous media are determined in the manner described below.

If the experimental data is:

Velocity (m/s)	Pressure Drop (Pa)
20.0	197.8
50.0	948.1
80.0	2102.5
110.0	3832.9

then an xy curve can be plotted to create a trendline through these points yielding the following equation

$$\Delta p = 0.27394v^2 + 4.68816v \tag{7.37}$$

where Δp is the pressure drop and v is the velocity.

Important:

Although the best fit curve may yield negative coefficients, it should be avoided when using the porous media model in Ansys Fluent.

Note that a simplified version of the momentum equation, relating the pressure drop to the source term, can be expressed as

$$\nabla p = S_i \tag{7.38}$$

or

$$\Delta p = -S_i \Delta n \tag{7.39}$$

Hence, comparing Equation 7.37 (p. 1331) to Equation 7.2 (p. 1313), yields the following curve coefficients:

$$0.27394 = C_2 \frac{1}{2} \rho \Delta n \tag{7.40}$$

with $\rho = 1.225$ kg/ m^3, and a porous media thickness, Δn, assumed to be 1 m in this example, the inertial resistance factor, $C_2 = 0.447$.

Likewise,

$$4.68816 = \frac{\mu}{\alpha} \Delta n \tag{7.41}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

with $\mu = 1.7894 \times 10^{-5}$, the viscous inertial resistance factor, $\frac{1}{\alpha} = 261996$.

Important:

Note that this same technique can be applied to the porous jump boundary condition. Similar to the case of the porous media, you have to take into account the thickness of the medium Δn. Your experimental data can be plotted in an xy curve, yielding an equation that is equivalent to Equation 7.147 (p. 1495). From there, you can determine the permeability α and the pressure jump coefficient C_2.

7.2.3.8.12. Using the Power-Law Model

If you choose to use the power-law approximation of the porous-media momentum source term (Equation 7.3 (p. 1313)), the only inputs required are the coefficients C_0 and C_1. Under **Power Law Model** in the **Fluid** dialog box, enter the values for **C0** and **C1**. Note that the power-law model can be used in conjunction with the Darcy and inertia models.

C0 must be in SI units, consistent with the value of **C1**.

7.2.3.8.13. Defining Porosity

To define the porosity, scroll down below the resistance inputs in the **Fluid** dialog box, and set the **Porosity** under **Fluid Porosity**. Note that the value of the **Porosity** must be in the range of `0 – 1` ; furthermore, the lower and upper limits (that is, `0` and `1`, respectively) are not allowed for the non-equilibrium thermal model.

You can also define the porosity using a user-defined function (UDF). The user-defined option becomes available in the corresponding drop-down list when the UDF has been created and loaded into Ansys Fluent. Note that the porosity defined in the UDF must utilize the `DEFINE_PROFILE` macro. For more information on creating and using user-defined functions, see the separate Fluent Customization Manual.

The porosity, γ, is the volume fraction of fluid within the porous region (that is, the open volume fraction of the medium). The porosity is used in the prediction of heat transfer in the medium, as described in Treatment of the Energy Equation in Porous Media (p. 1315), and in the time-derivative term in the scalar transport equations for unsteady flow, as described in Effect of Porosity on Transient Scalar Equations (p. 1317). It also impacts the calculation of reaction source terms and body forces in the medium. These sources will be proportional to the fluid volume in the medium. If you want to represent the medium as completely open (no effect of the solid medium), you should set the porosity equal to 1.0 (the default). When the porosity is equal to 1.0, the solid portion of the medium will have no impact on heat transfer or thermal/reaction source terms in the medium.

7.2.3.8.14. Specifying the Heat Transfer Settings

You can model heat transfer in the porous material, with or without the assumption of thermal equilibrium between the medium and the fluid flow. Note that heat transfer is not available for inviscid flow.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.2.3.8.14.1. Equilibrium Thermal Model

To specify that the porous medium and the fluid flow are in thermal equilibrium, scroll down below the resistance inputs in the **Fluid** dialog box to the **Heat Transfer Settings** group box and select **Equilibrium** from the **Thermal Model** list (this is the default selection). Then you must specify the material contained in the porous medium by selecting the appropriate solid in the **Solid Material Name** drop-down list.

If you want to check or modify the properties of the selected material, you can click **Edit...** to open the **Edit Material** dialog box; this dialog box contains just the properties of the selected material, not the full contents of the standard **Create/Edit Materials** dialog box. You can define the **Thermal Conductivity** of the porous material using a user-defined function (UDF), in order to define a non-isotropic thermal conductivity. The user-defined option becomes available in the corresponding drop-down list when the UDF has been created and loaded into Ansys Fluent. Note that the non-isotropic thermal conductivity defined in the UDF must utilize the `DEFINE_PROPERTY` macro. For more information on creating and using user-defined function, see the separate Fluent Customization Manual.

7.2.3.8.14.2. Non-Equilibrium Thermal Model

Note:

The non-equilibrium thermal model is incompatible with the density-based solver.

The assumption of thermal equilibrium between the solid medium and the fluid flow is not appropriate for all simulations, as the presence of different geometric length scales (for example, pore sizes) and physical properties of solid and liquid phases may result in local temperature differences between the phases. Examples of when a non-equilibrium thermal model may be suitable include the simulation of light-off for exhaust after-treatment, fuel cells, catalytic converters, and so on.

The non-equilibrium thermal model available for porous media in Ansys Fluent is based on a dual cell approach. This approach is referred to as "dual cell" because it involves a second solid cell zone that overlaps (that is, is spatially coincident with) the porous fluid zone; the two zones are solved simultaneously and are coupled only through heat transfer. Ansys Fluent can automatically create a solid zone for you that is a duplicate of the porous fluid zone; otherwise, you can create a duplicate cell zone manually using the `mesh/modify-zones/copy-move-cell-zone` text command before you enable the non-equilibrium thermal model, or make sure that the mesh you read contains two cell zones in the region where the porous medium will be defined. You should ensure that the duplicate zone is defined as a solid zone, and that the two zones have similar levels of mesh refinement (as one-to-one mapping will be employed between the cell centroids of the fluid zone and the solid zone).

Important:

When setting up both the porous fluid zone and the overlapping solid zone, note that the non-equilibrium thermal model is not supported for zones that undergo (or are adjacent to zones that undergo) changes to the geometry or mesh, such as dynamic mesh zones or zones that undergo hanging node adaption, utilize the mesh morpher/optimizer, or are involved in fluid-structure interaction (FSI) applications.

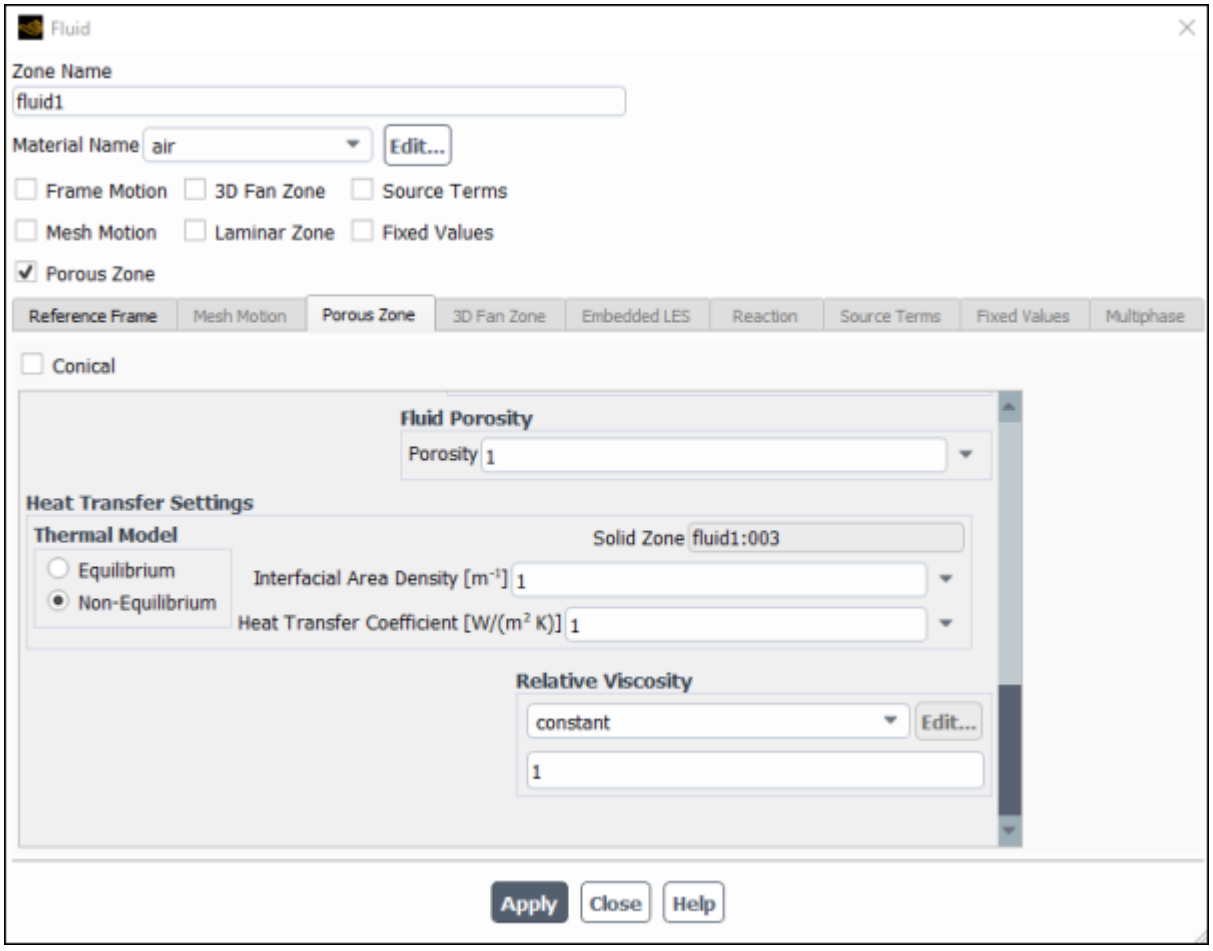
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The instructions that follow assume you have already performed steps 1–7 in User Inputs for Porous Media (p. 1320). Before you enable the non-equilibrium thermal model, click **OK** in the **Fluid** dialog box, in order to save your settings in the **Porous Zone** tab; note that if you do not save your settings, they will be reset to the default values when you enable the non-equilibrium thermal model. Then reopen the **Fluid** dialog box and scroll down below the resistance inputs in the **Porous Zone** tab. Select **Non-Equilibrium** from the **Thermal Model** list in the **Heat Transfer Settings** group box (see Figure 7.24: The Heat Transfer Settings Group Box of the Fluid Dialog Box (p. 1334)); this will enable the dual cell approach and display the associated GUI input controls. If a solid zone that is spatially coincident with the porous fluid zone does not already exist, use the **Question** dialog box that opens to automatically create one. The name of the newly created solid cell zone will then be displayed in the **Solid Zone** text box of the **Fluid** dialog box.

Important:

Note that the **Non-Equilibrium** option button is not available if a radiation and/or multiphase model is enabled, as such a combination is not supported.

Figure 7.24: The Heat Transfer Settings Group Box of the Fluid Dialog Box



Next, define A_{fs} and h_{fs} (as described in Non-Equilibrium Thermal Model Equations (p. 1316)) for **Interfacial Area Density** and **Heat Transfer Coefficient**, respectively; you can define these settings as a **Constant**, a **New Input Parameter...**, or as a user-defined function. The **user-**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

defined option becomes available in the corresponding drop-down list when the UDF has been created and loaded into Ansys Fluent. Note that the UDF must utilize the `DEFINE_PROFILE` macro. For more information on creating and using user-defined functions, see the separate Fluent Customization Manual.

When you are finished setting up the porous fluid zone, you should verify that the solid zone created in the previous step has the appropriate settings. Note the name of the zone displayed in the **Solid Zone** text box of the **Heat Transfer Settings** group box (see Figure 7.24: The Heat Transfer Settings Group Box of the Fluid Dialog Box (p. 1334)), and then double-click that zone in the **Zone** list of the **Cell Zone Conditions** task page to open the **Solid** dialog box. Then, verify that an appropriate selection is made for **Material Name**. If you want to check or modify the properties of the selected material, you can click **Edit...** to open the **Edit Material** dialog box; this dialog box contains just the properties of the selected material, not the full contents of the standard **Create/Edit Materials** dialog box. You can define the **Thermal Conductivity** of the solid material using a user-defined function (UDF), in order to define a non-isotropic thermal conductivity. The user-defined option becomes available in the corresponding drop-down list when the UDF has been created and loaded into Ansys Fluent. Note that the non-isotropic thermal conductivity defined in the UDF must utilize the `DEFINE_PROPERTY` macro. For more information on creating and using user-defined functions, see the separate Fluent Customization Manual.

Important:

For transient simulations using the Non-Equilibrium Thermal Model with low porosity (typically < 0.2), it is recommended to increase the Solid Time Step Size as described in Specifying the Solid Time Step Size (p. 2133). A value ~1s or the Automatic option can help with solution stability and convergence.

Note that when postprocessing simulations that utilize the non-equilibrium thermal model, you can display the energy source due to the temperature difference between the fluid and solid zones using the **Non-Equilibrium Thermal Model Source** variable in the **Temperature...** category. Furthermore, attention must be paid to the fact that there are overlapping cell zones (that is, a fluid and a solid zone) in the porous region. For example:

- When creating an isosurface and making selections from the **From Zones** selection list of the **Iso-Surface** dialog box, you should never select both the porous fluid zone and the overlapping solid zone at the same time. Note that if no selections are made in this list, then all the cell zones are selected.
- When making selections from the **Surfaces** list of the **Contours** dialog box, you should not select a surface that is associated with the porous fluid zone and a surface associated with the overlapping solid zone at the same time, if those surfaces are spatially coincident.
- When postprocessing the thermal conductivity property in the porous region, the value that is reported for the fluid zone is the thermal conductivity of the fluid material scaled by the porosity (γk_f) and for the overlapping solid zone the value reported is the thermal conductivity of the solid zone scaled by the complement of the porosity ($(1-\gamma)k_s$); where γ is the porosity, k_f is the fluid phase thermal conductivity (including the turbulent contribution, k_t), and k_s is the solid medium thermal conductivity.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.2.3.8.15. Specifying the Relative Viscosity

The relative viscosity can be used to account for the effect of the porous media on the diffusion term in the momentum equation. By default, the relative viscosity is set to a constant value of 1 (that is, the effective viscosity is equal to the molecular viscosity). You can choose to model the relative viscosity using one of the models described in Relative Viscosity in Porous Media (p. 1315), or you can specify a user-defined function using a `DEFINE_PROPERTY` macro.

When you define multiple porous zones, the last value you enter for the relative viscosity will be applied to compute the effective viscosity for all porous zones in your simulation. If you want to simulate different effective viscosities in different porous zones, specify the **Viscosity** property of the porous material directly via user-defined function using the `DEFINE_PROPERTY` macro (in the **Create/Edit Materials** dialog box).

7.2.3.8.16. Specifying the Relative Permeability

The relative permeability of a phase denotes its ability to transmit the phase material when its saturation (volume fraction) is less than 100%.

Reservoir engineers often resort to empirical models or measurement curves to determine the relative and, therefore, the effective permeabilities. In Fluent, the Corey power law model [25] (p. 5656) is available to account for the relative permeability for the two-phase flow through porous media. The Corey correlations of the relative permeability can be represented as follows:

$$K_{r,q}=K^{0}_{r,q}\tilde{S}_{q}^{nq} \tag{7.42}$$

where:

$K^{0}_{r,q}$ is the reference phase relative permeability

$\tilde{S}_{q}$ is the normalized saturation in the q th phase

nq is the Corey exponent for the q th phase

In Fluent the phase saturation is the phase volume fraction. Thus $\tilde{S}_{q}$ can be expressed as:

$$\tilde{S}_{q}=\tilde{\alpha}_{q}=\frac{\alpha_{q}-\alpha_{qr}}{1-\sum_{q=0}^{n-1}\alpha_{qr}} \tag{7.43}$$

where α_{q} and α_{qr} are the volume fraction and the volume fraction residual in the q th phase, respectively.

For the two-phase oil-water flow in a water-wet-system, the relative permeabilities can be obtained from:

$$\begin{aligned} K_{r,w}&=K^{0}_{r,w}\tilde{\alpha}_{w}^{nw} \\ K_{r,o}&=K^{0}_{r,o}\left(1-\tilde{\alpha}_{w}\right)^{no} \end{aligned} \tag{7.44}$$

where:

Subscripts w and o refer to the water and oil phases, respectively

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$K^0_{r,w}$ and $K^0_{r,o}$ are the reference phase relative permeabilities for the wetting and non-wetting phases, respectively

nw and no are the Corey exponents for the two phases

The Corey correlation is often used for approximation of the relative permeabilities, particularly for water flooding type scenarios. The relative permeability curves of the oil (or the non-wetting phase) is usually an S-shaped curve and of the water (or the wetting phase) is a concave upward curve.

Alternatively, if relative permeability data for one or two phases are available as tabular functions of other solution variables, you can use generic text files to input such data to define phase relative permeability as described in Reading Files in Tabular Format (p. 944).

To model the relative permeability in Ansys Fluent:

1. Set parameters for the **mixture** phase.

   Note:

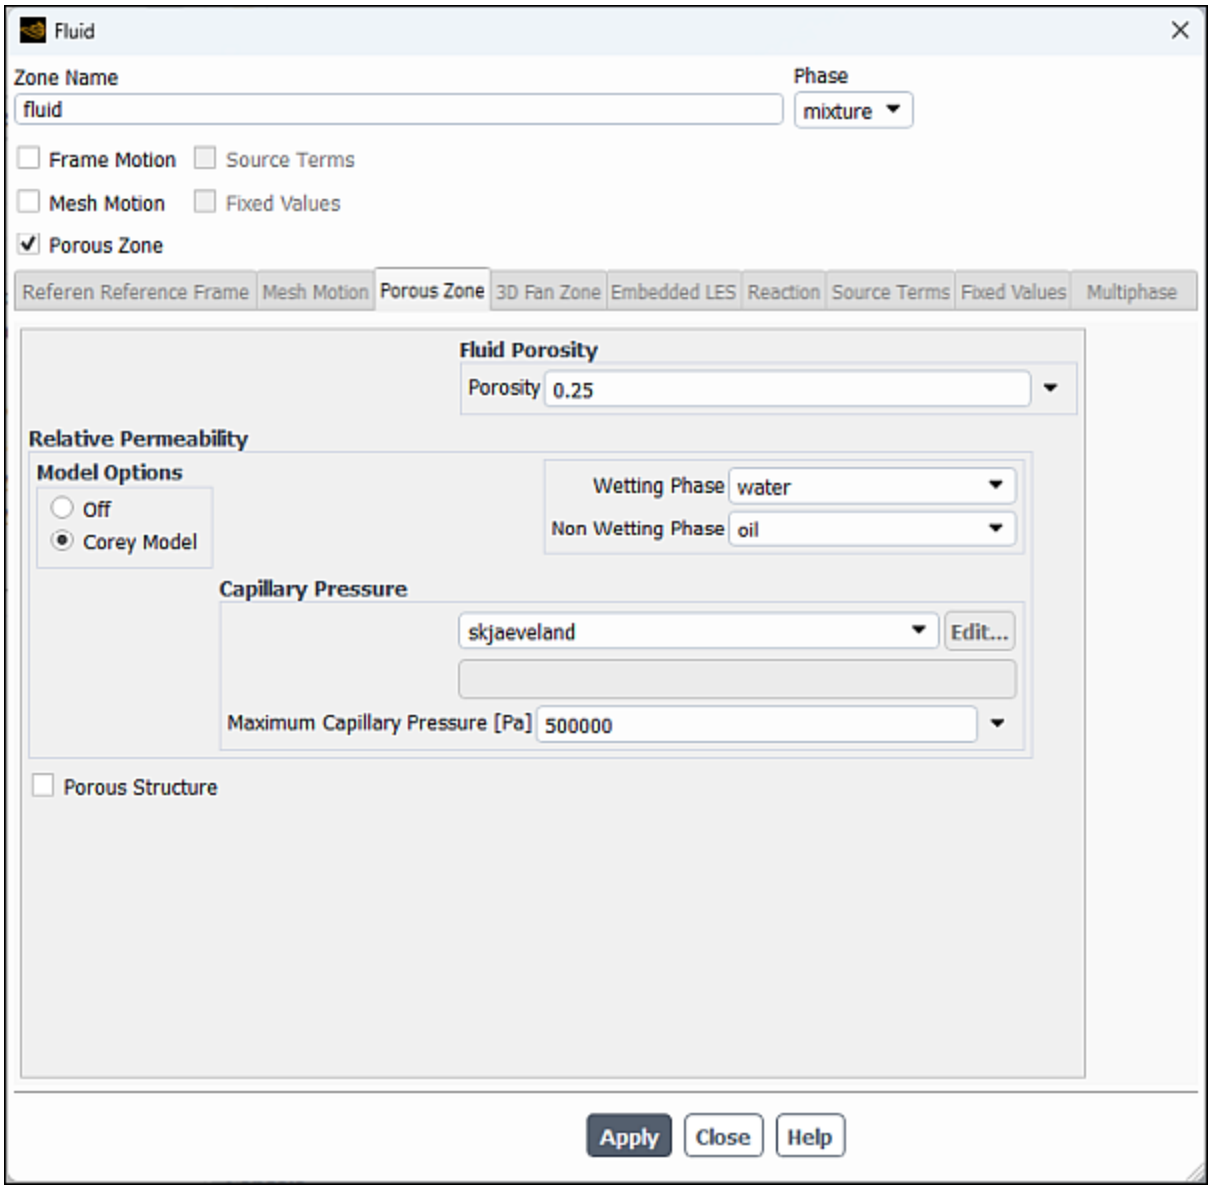
   The phase can be selected from the **Phase** drop-down list either in the **Cell Zone Conditions** task page or in the **Fluid** dialog box.

   a. In the **Fluid** dialog box, make sure that **mixture** is selected from the **Phase** drop-down list.

   b. In the **Porous Zone** tab, under **Relative Permeability**, select **Corey Model**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.25: The Fluid Dialog Box: Relative Permeability



c. From the drop-down lists, select **Wetting Phase** and **Non Wetting Phase**.

> **Important:**
>
> Although Equation 7.42 (p. 1336) through Equation 7.44 (p. 1336) are valid for any given phase, care must be exercised in defining the wetting and non-wetting phases.

d. Click **Apply**.

2. Set conditions for the wetting phase.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

a. In the **Fluid** dialog box, make sure that the wetting phase is selected from the **Phase** drop-down list.

b. In the **Porous Zone** tab, specify the following parameters in the **Wetting Phase Relative Permeability** group box:

Minimum Relative Permeability

sets a lower limit for the relative permeability for the wetting phase. A low value increases impact of the resistance due to relative permeability effects on the flow. This helps to avoid saturation overshoots and undershoots (that is, phase saturation dropping below residual values) in simulations carried out for a long period of time. The default value is 1.e-8. The default should work for most cases, but may be lowered in case undershoot problems persist.

Reference Relative Permeability

is $K^0_{r,w}$ in Equation 7.44 (p. 1336). This parameter is available only when the **tabular** option is disabled.

Corey Exponent

is nw in Equation 7.44 (p. 1336).

Residual Saturation

is the residual volume fraction of the wetting phase. This parameter is available only when the **tabular** option is disabled.

If, instead, you wish to specify the relative permeability parameters for the wetting phase in the tabular format, follow these steps:

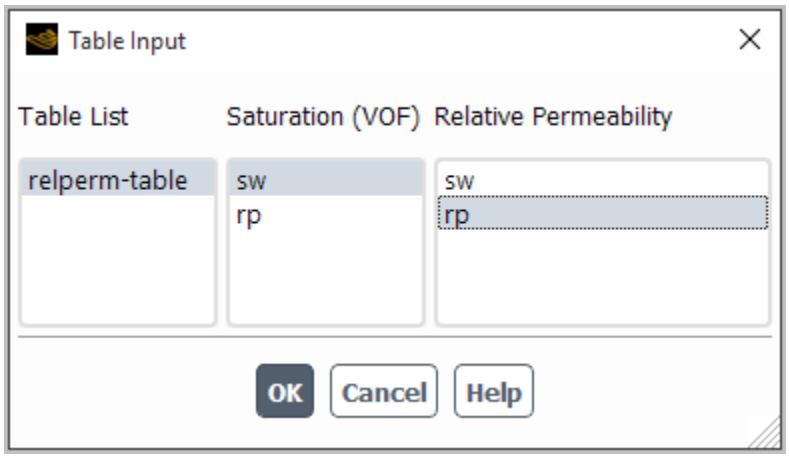
i. Select **tabular** and click **Edit...**.

> **Note:**
>
> Prior to using the **tabular** option, you must read a text file containing phase relative permeability data as described in Capillary Pressure Data in a Tabular Format (p. 1344).

ii. In the **Table Input** dialog box that opens, select the table appropriate for your fluid zone from the **Table List** and the names of the columns from the **Saturation (VOF)** and **Relative Permeability** selection lists.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.26: The Table Input Dialog Box for Relative Permeability



See Capillary Pressure Data in a Tabular Format (p. 1344) for details about the text file format.

c. Click **Apply**.

3. Similarly, set conditions for the non-wetting phase.

a. In the **Fluid** dialog box, make sure that the non-wetting phase is selected from the **Phase** drop-down list.

b. In the **Porous Zone** tab, specify the following parameters in the **Non Wetting Phase Relative Permeability** group:

Minimum Relative Permeability

sets a lower limit for the relative permeability for the non-wetting phase. This item is similar to **Minimum Relative Permeability** for the wetting phase.

Reference Relative Permeability

is $K^0_{r,o}$ in Equation 7.44 (p. 1336). This parameter is available only when the **tabular** option is disabled.

Corey Exponent

is no in Equation 7.44 (p. 1336).

Residual Saturation

is the residual volume fraction of the non-wetting phase. This parameter is available only when the **tabular** option is disabled.

If, instead, you wish to specify the relative permeability parameters for the non-wetting phase in the tabular format, select **tabular**. The inputs are similar to the tabular specification for the wetting phase.

c. Click **Apply**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

On rare occasions, the saturation may still fall below residual saturation. You can fix the affected phase to its residual saturation and allow the other phase to pass through normally by issuing the following text commands:

```
solve/set/multiphase-numerics/porous-media/relative-permeability

enable fix option below residual saturation? [no] yes
```

Note:

The previous text command is not supported for cases that use the tabular specification method for phase relative permeability.

7.2.3.8.17. Specifying the Capillary Pressure

When using the Eulerian multiphase model, you can optionally specify a sub-model for capillary pressure.

When two or more phases are present in pores, one of the phase (usually water) has a preference for the pore surfaces. This phase is referred to as the wetting phase, while the other phase is called the non-wetting phase. The boundary between the phases present in a porous medium is also curved, due to interfacial tension between the fluid, and this gives rise to a difference in the pressure across the interface:

$$P_c = P_{nw} - P_w \tag{7.45}$$

where P_{nw} and P_w are the non-wetting and wetting phase pressures, respectively. The difference, P_c is the capillary pressure. It presents a significant driving force under the conditions of low flow pressure and high volume fraction.

At the pore scale, capillary pressure depends primarily on the pore geometric characteristics (sizes, distributions, etc.), interfacial tensions and wettability (contact angles). At the Macro scale the capillary pressure is generally assumed to be a function of the saturation of the wetting fluid:

$$P_c = P_c\left(S_{wetting}\right) = P_c\left(\alpha_{wetting}\right) \tag{7.46}$$

Its value is often obtained either by measurements or correlations.

In Fluent, the capillary pressure effect is modeled as an additional source term in the wetting phase. Additional information is provided in the following sections:

7.2.3.8.17.1. Brooks-Corey Model

7.2.3.8.17.2. Van-Genuchten Model

7.2.3.8.17.3. Leverett J-Function

7.2.3.8.17.4. Skjaeveland Model

7.2.3.8.17.5. Capillary Pressure Data in a Tabular Format

7.2.3.8.17.6. Capillary Pressure Usage

7.2.3.8.17.7. Modeling Capillary Pressure as Diffusion

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.2.3.8.17.1. Brooks-Corey Model

The Brooks-Corey model [25] (p. 5656) proposed the following relationship for capillary pressure for primary drainage, in which the porous media initially saturated with water is invaded with oil phase:

$$P_{c,q}=P_e\left(S_{eq}\right)^{-1/nb} \tag{7.47}$$

where S_{eq} is the resulting normalized (effective) saturation:

$$S_{eq}=\alpha_{eq}=\frac{\alpha-\alpha_q^{\min}}{\alpha_q^{\max}-\alpha_q^{\min}} \tag{7.48}$$

where $\alpha_q^{\min}$ and $\alpha_q^{\max}$ are the minimum and maximum volume fraction (saturation) values, respectively. By default $\alpha_q^{\min}=\alpha_{\mathrm{qr}}$ and $\alpha_q^{\max}=1$ where α_{qr} is the residual saturation of phase q The value of α_{eq} is limited to values greater than 0.001 in order to avoid an infinite value for capillary pressure.

In order to solve Equation 7.47 (p. 1342), the entry pressure, P_e, and the parameter nb related to the pore size are required. The default values in Fluent are $P_e=440Pa$ and $nb=1.124$ which are appropriate for air-water flow in sand [27] (p. 5656).

7.2.3.8.17.2. Van-Genuchten Model

Another well established parametric model was proposed by van Genuchten [46] (p. 5657):

$$P_{c,q}=P_g\left[\left(S_{eq}\right)^{-1/m_g}-1\right]^{1/n_g} \tag{7.49}$$

where P_g is the entry pressure. n_g is the pore size distribution and $m_g=1-{}^{1}/_{n_g}$. The default values inFluent are $P_g=667Pa$ and $n_g=2.68$ which are appropriate for air-water flow in sand [27] (p. 5656).

7.2.3.8.17.3. Leverett J-Function

The J-function was developed by Leverett in an attempt to extend the pore-scale capillary pressure formulation by Washburn [27] (p. 5656) to a Macro-scale capillary pressure model. Leverett proposed that the averaged pore radius can be expressed in terms of porosity and permeability:

$$r_p=\sqrt{\frac{8K_{e,q}}{\gamma}} \tag{7.50}$$

Furthermore, he acknowledged that the capillary pressure should depend on porosity and permeability. By analogy to the Washburn equation, he developed a dimensionless J-function [82] (p. 5659):

$$J\left(S_q\right)=J\left(\alpha_q\right)=\frac{P_{c,q}}{\sigma\cos\theta_q}\sqrt{\frac{K_{e,q}}{\gamma}} \tag{7.51}$$

$$J(S_q)=a\left(S_q\right)^b \tag{7.52}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where σ is the surface tension, θ_q is the wetting or contact angle, and a and b are fitting parameters. Various empirical J-functions can be developed to estimate capillary pressure. In the Fluent, the following formulation is used:

$$P_{c,q}=\begin{cases}\sigma\cos\theta_q\sqrt{\frac{\gamma}{K_{e,q}}}\left[1.417\left(1-\alpha_q\right)-2.12\left(1-\alpha_q\right)^2+1.263\left(1-\alpha_q\right)^3\right] & \theta_q\leq 90^\circ \\ \sigma\cos\theta_q\sqrt{\frac{\gamma}{K_{e,q}}}\left[1.417\alpha_q-2.12\alpha_q^2+1.263\alpha_q^3\right] & \theta_q>90^\circ\end{cases} \tag{7.53}$$

This is the same formulation as is used in the Fluent Fuel Cell Module (see Liquid Water Formation, Transport, and its Effects (Low-Temperature PEMFC Only) in the *Fluent Theory Guide*).

7.2.3.8.17.4. Skjaeveland Model

All of the above-mentioned capillary pressure models (Brooks-Corey, Van-Genuchten, Leverett J-Function) are limited to primary drainage processes. Water saturation decreases in a primary drainage process. To model a displacement process where flooding is important, such as water-drive, models that describe imbibition are required. However, most reservoirs are mixed wettabilty and for these systems a more comprehensive model that describes both drainage and imbibition processes is required. The Skjaeveland model for capillary pressure encompasses these features.

The Skjaeveland model [140] (p. 5663) for capillary pressure treats the two fluids symmetrically for wettability. The Skjaeveland capillary pressure curve is defined by Equation 7.54 (p. 1343).

$$P_{c,q}=\frac{c_w}{\left(\left(\alpha_q-\alpha_{qr}\right)/\left(1-\alpha_{qr}\right)\right)^{a_w}}-\frac{c_{nw}}{\left(\left(1-\alpha_q-\alpha_{pr}\right)/\left(1-\alpha_{pr}\right)\right)^{a_{nw}}} \tag{7.54}$$

Where $P_{c,q}$ is the capillary pressure of the q^{th} phase, a_w and a_{nw} are fitting parameters, c_w and c_{nw} are constants, and α_q and α_p are the volume fractions of the two phases. w and nw subscripts refer to wetting and non-wetting phases, respectively.

The positive part of the capillary pressure curve is defined by c_w and a_w. c_{nw} and a_{nw} define the negative portion of the capillary pressure curve. The effects of varying c_w, a_w, c_{nw}, and a_{nw} on the capillary pressure curve are shown in Figure 7.27: Skjaeveland Correlation Behavior (p. 1344) [140] (p. 5663).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.27: Skjaeveland Correlation Behavior

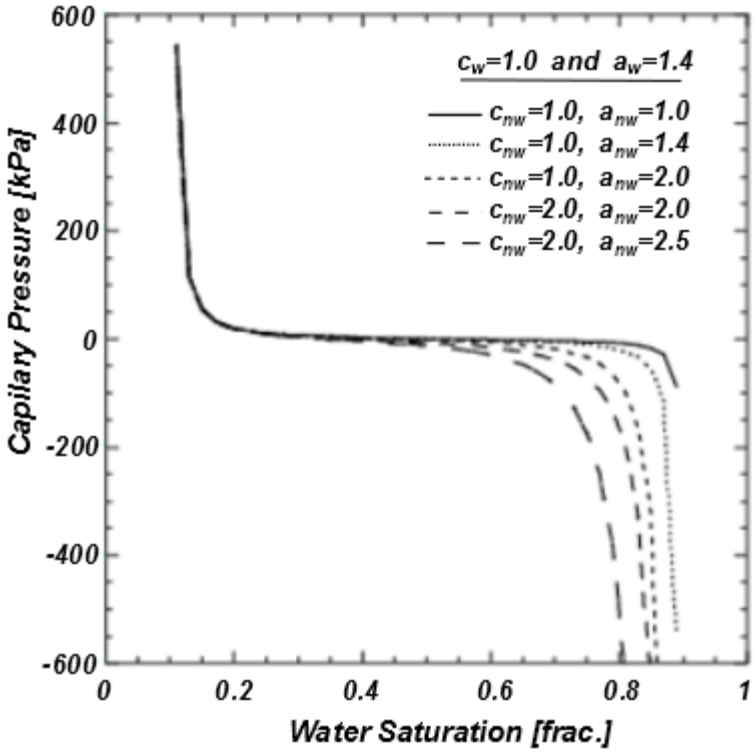


Figure 7.27: Skjaeveland Correlation Behavior (p. 1344) shows that there is a lot of flexibility in the capillary pressure curve. You can add further flexibility to the capillary pressure curve by estimating the residual oil saturation. Note that by varying c_w and a_w you can modify the cross-over point (while keeping c_{nw} and a_{nw} unchanged).

Parameter	Default Value
c_w	9.e5
c_{nw}	9.e5
a_w	0.05
a_{nw}	0.05

7.2.3.8.17.5. Capillary Pressure Data in a Tabular Format

Often, field data for capillary pressure are available as tabular functions of other solution variables. In, Ansys Fluent, you can use a tabular method to specify capillary pressure. Multiple files can be used to specify zone-specific properties, for example, different models for capillary pressure for different zones.

The text file format and the table reading procedure are described in Reading Files in Tabular Format (p. 944).

An example of the data file for the capillary pressure variable is shown below.

```
Default-Skjaevland-Model
Sw          Pc
0.2122      195399.0883
0.2245      156423.6016
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
0.2367      134012.8962
0.249       117936.4991
0.2612      105469.0929
0.2735      95079.83957
0.2857      86245.04955
0.298       78405.02466
```

Row 1 – The name of the table. The name should not exceed 128 characters and contain no spaces. For example, `Default-Skjaevland-Model` and `Default_Skjaevland_Model` are acceptable names.

Row 2 – Column names for the table input data (`Sw` and `Pc` in the above example).

Row 3 and all consecutive rows – Data points of the saturation and the corresponding capillary pressure values as a function of the saturation.

See Capillary Pressure Usage (p. 1345) for more information on tabular input for capillary pressure.

7.2.3.8.17.6. Capillary Pressure Usage

To model the capillary pressure:

1. In the **Fluid** dialog box for the phase mixture, in the **Porous Zone** tab, select **Corey Model** (**Model Options** group box).

2. Select a model from the drop-down list under **Capillary Pressure**. You can choose from the following models:

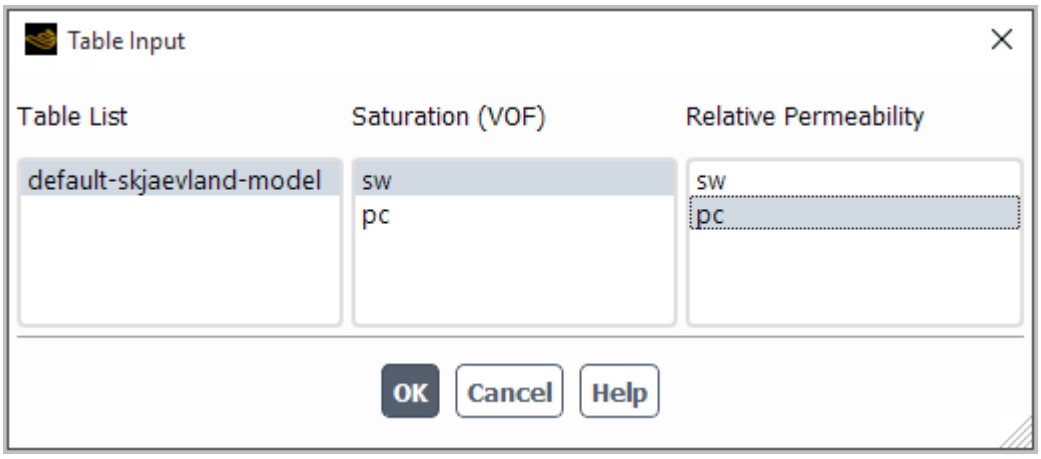
   - **brooks-corey**
   - **van-genuchten**
   - **leverett-j-function**
   - **skjaeveland**
   - **tabular**

     Note that prior to using the **tabular** option, you must load a text file containing capillary pressure data as described in Capillary Pressure Data in a Tabular Format (p. 1344).

3. (tabular only) In the **Table Input** dialog box that opens when you select **tabular**, select the table appropriate for your fluid zone from the **Table List** and the names of the columns from the **Saturation (VOF)** and **Capillary Pressure** selection lists.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.28: The Table Input Dialog Box for Capillary Pressure



For details about capillary pressure table files, see Capillary Pressure Data in a Tabular Format (p. 1344).

Note:

You can also define capillary pressure as a tabular function by using the text commands available under `define/boundary-conditions/set/fluid`. Once you enter `mixture` for `domain id/name`, you can select the `capillary-pressure` TUI option, set the method to `tabular` and specify its parameters.

4. Specify **Maximum Capillary Pressure**.

   The capillary pressure graph exhibits asymptotic behavior at the residual saturation of wetting and non-wetting phases where the capillary pressure approaches plus and minus infinity (see Figure 6.98: The Activate Cell Zones Dialog Box (p. 1256)). For this reason, the capillary pressure must be limited to avoid numerical problems.

5. (Brooks-Corey model only) In the secondary phase **Fluid** dialog box, in the **Porous Zone** tab, specify the model-specific parameters (**Brooks-Corey Model Inputs** group box):

   Entry pressure

   is P_e in Equation 7.47 (p. 1342).

   Pore size exponent

   is the parameter nb in Equation 7.47 (p. 1342).

6. (Van-Genuchten model only) In the secondary phase **Fluid** dialog box, in the **Porous Zone** tab, specify the model-specific parameters (**Van-Genuchten Model Inputs** group box):

   Entry pressure

   is P_g in Equation 7.49 (p. 1342).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Pore size exponent

is n_g in Equation 7.49 (p. 1342).

7. (Skjaeveland model only) In the **Fluid** dialog boxes for the primary and secondary phases, in the **Porous Zone** tab, specify the model-specific parameters (**Skjaeveland Model Inputs** group box):

   Entry pressure

   is a constant c_w for the wetting phase and c_{nw} for the non-wetting phase in Equation 7.54 (p. 1343).

   Pore size exponent

   is a_w for the wetting phase and a_{nw} for the non-wetting phase in Equation 7.54 (p. 1343).

8. (Leverett J-Function model only) Specify the following model-specific parameters:

   1. In the **Fluid** dialog boxes for the secondary phase, in the **Porous Zone** tab, in the **Leverett J-Function Model Inputs** group box, specify **Contact Angle** (θ_q in Equation 7.51 (p. 1342)).

   2. In the **Multiphase Model** dialog box, go to the **Phase Interaction** > **Forces** tab, and select **Surface Tension Force Modeling** (**Global Options** group box). Then in the **Force Setup** group box, specify **Surface Tension Coefficient** (σ in Equation 7.51 (p. 1342)).

Alternatively, you can specify a user-defined function that calculates the capillary pressure using a `DEFINE_EXCHANGE_PROPERTY` macro.

Note:

When modeling the capillary pressure, you should ensure that the wetting phases are chosen as the secondary phases.

Postprocessing

The following additional field variable is available for secondary phases:

- **Capillary-Pressure**

  Note that, although this item is available for both non-wetting and wetting phases, meaningful values are reported only for the wetting phase.

7.2.3.8.17.7. Modeling Capillary Pressure as Diffusion

By default, the capillary pressure term is included as a source in the wetting phase momentum equation as shown in Equation 7.22 (p. 1319). For two-phase cases, you can use an alternative approach where capillary pressure is modeled as a diffusion term in the wetting phase continuity equation. This approach provides numerical robustness and stability for certain cases.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The gradient of capillary pressure is expressed as a function of the wetting phase saturation α_w:

$$\nabla p_c = \frac{\partial p_c}{\partial \alpha_w} \nabla \alpha_w \tag{7.55}$$

The calculation of the gradient of capillary pressure with respect to the wetting phase volume fraction can be done analytically.

To model capillary pressure as diffusion, issue the following text command:

```
solve/set/multiphase-numerics/porous-media/capillary-pressure-as-diffusion?
model capillary pressure as diffusion? [no] yes
```

Note:

- When modeling the capillary pressure as diffusion, the secondary phase must be the wetting phase.
- Regardless of whether the flow is laminar or turbulent, Ansys Fluent uses only the viscous resistance in the calculation of capillary pressure gradient.

7.2.3.8.18. Defining Sources

If you want to include effects of the heat generated by the porous medium in the energy equation, enable the **Source Terms** option and set a nonzero **Energy** source. For porous media, energy source terms on the solid and gas sides are applied exactly as entered with no adjustment for porosity. A source term of 100 W/m ^{3} specified for a solid zone of volume 1.0 m ^{3} will, therefore, deliver 100 W even if the solids make up only 60% of that volume. You may also define sources of mass, momentum, turbulence, species, or other scalar quantities, as described in Defining Mass, Momentum, Energy, and Other Sources (p. 1360).

7.2.3.8.19. Defining Fixed Values

If you want to fix the value of one or more variables in the fluid region of the zone, rather than computing them during the calculation, you can do so by enabling the **Fixed Values** option. See Fixing the Values of Variables (p. 1355) for details.

7.2.3.8.20. Suppressing the Turbulent Viscosity in the Porous Region

As discussed in Treatment of Turbulence in Porous Media (p. 1317), turbulence will be computed in the porous region just as in the bulk fluid flow. If you are using one of the turbulence models (other than the Large Eddy Simulation model) and you want the turbulence generation to be zero in the porous zone, turn on the **Laminar Zone** option in the **Fluid** dialog box. Refer to Specifying a Laminar Zone (p. 1300) for more information about suppressing turbulence generation.

7.2.3.8.21. Specifying the Rotation Axis and Defining Zone Motion

Inputs for the rotation axis and zone motion are the same as for a standard fluid zone. See Inputs for Fluid Zones (p. 1299) for details.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.2.3.9. Solution Strategies for Porous Media

In general, you can use the standard solution procedures and solution parameter settings when your Ansys Fluent model includes porous media. You may find, however, that the rate of convergence slows when you define a porous region through which the pressure drop is relatively large in the flow direction (for example, the permeability, α, is low or the inertial factor, C_2, is large). This slow convergence can occur because the porous media pressure drop appears as a momentum source term—yielding a loss of diagonal dominance—in the matrix of equations solved. The best remedy for poor convergence of a problem involving a porous medium is to supply a good initial guess for the pressure drop across the medium.

Similarly, **Standard Initialization** is the recommended initialization method for porous media simulations. The default **Hybrid Initialization** method does not account for the porous media properties, and depending on boundary conditions, may produce an unrealistic initial velocity field. For porous media simulations, the **Hybrid Initialization** method should only be used with the **Maintain Constant Velocity Magnitude** option.

Another possible way to deal with poor convergence is to temporarily disable the porous media model (by turning off the **Porous Zone** option in the Fluid Dialog Box (p. 4909)) and obtain an initial flow field without the effect of the porous region. With the porous media model turned off, Ansys Fluent will treat the porous zone as a fluid zone and calculate the flow field accordingly. Once an initial solution is obtained, or the calculation is proceeding steadily to convergence, you can enable the porous media model and continue the calculation with the porous region included. (This method is not recommended for porous media with high resistance.)

Simulations involving highly anisotropic porous media may, at times, pose convergence troubles. You can address these issues by limiting the anisotropy of the porous media coefficients ($1/\ \alpha_{ij}$ and $C_{2_{i,j}}$) to two or three orders of magnitude. Even if the medium's resistance in one direction is infinite, you do not need to set the resistance in that direction to be greater than 1000 times the resistance in the primary flow direction.

For cases that involve the non-equilibrium thermal model, using a default meshing partitioning method may cause convergence issues and /or solution dependence on the number of processors. In such a case, you should chose a meshing partition method that does not place the partition interface in the regions of significant variations in thermal conductivity and/or mesh size. For more information, see Mesh Partitioning Methods (p. 4297).

7.2.3.10. Postprocessing for Porous Media

The impact of a porous region on the flow field can be determined by examining either velocity components or pressure values. Graphical plots (including report plots of force|lift|drag|moment report definitions— Force and Moment Report Definitions (p. 4072), XY plots— XY Plots of Solution Data (p. 4027) , cumulative force/moment plots— Cumulative Force, Moment, and Coefficients Plots (p. 4061), and contour— Displaying Contours and Profiles (p. 3874) or vector— Displaying Vectors (p. 3886) plots) or alphanumeric reports of the following variables/functions may be of interest:

- **X**, **Y**, **Z Velocity** (in the **Velocity...** category)
- **Static Pressure** (in the **Pressure...** category)

These variables are contained in the specified categories of the variable selection drop-down list that appears in postprocessing dialog boxes.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note that thermal reporting in the porous region is defined as follows:

$$k_{eff} = \gamma k_f + \left(1 - \gamma\right) k_s \tag{7.56}$$

where

γ = porosity of the medium

k_f = fluid phase thermal conductivity (including the turbulent contribution, k_t)

k_s = solid medium thermal conductivity

Important:

- Volume and mass integral reports do not account for porosity effects in the porous media.
- For porous media involving surface reactions, you can display/report the surface reaction rates using the **Arrhenius Rate of Reaction-n** in the **Reactions...** category of the variable selection drop-down list.

Important:

Special care must be taken when postprocessing a porous media simulation that utilizes the non-equilibrium thermal model. See Non-Equilibrium Thermal Model (p. 1333) for details.

7.2.4. 3D Fan Zones

3D fan zones are fluid cell zones that simulate the effect of an axial fan by applying a distributed momentum source in a toroid-shaped fluid volume (that is, a blade-swept volume). This is in contrast to fan boundary conditions (for example, a boundary zone of type **fan** or **intake-fan**), which are based on a lumped parameter model in which the fan is considered to be infinitely thin and a discontinuous pressure rise is specified as a function of velocity. 3D fan zones have the following advantages:

- 3D fan zones can calculate swirl and radial velocities, as opposed to fan boundary conditions, which are mainly used to simulate the axial flow and require you to input swirl and radial coefficients.
- The results for 3D fan zones can be comparable to moving reference frame (MRF) simulations, and do not require modeling 3D rotating fan blade geometries.
- 3D fan zones can simulate a fan even if the available fan curve data was measured at different operating conditions than that of the simulation.

Note:

Fluid zones designated as 3D fan zones cannot have non-conformal interfaces.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.2.4.1. Momentum Equations for 3D Fan Zones

The following equations are used in the 3D fan zone for the momentum sources in the axial, tangential, and radial directions, which mimic the effect of the fan on the fluid. The tangential momentum source is based on a turbomachinery relation, whereas the radial momentum source is based on a centrifugal force balance.

$$\text{Axial: } S_a = \Delta P(Q)/h \tag{7.57}$$

$$\text{Tangential: } S_t = \begin{cases} \frac{2W_{fan}r}{c_1|\Omega_{operating}|} & \text{for } R_h < r \le R_{ip} \\ \frac{2W_{fan}R_{ip}^2}{c_1 r|\Omega_{operating}|} & \text{for } R_{ip} < r < R_t \end{cases} \tag{7.58}$$

$$\text{Radial: } S_r = \frac{\rho V_\phi^2}{r} \tag{7.59}$$

where

$\Delta P(Q)$ = pressure rise across the fan for a given axial flow rate Q

h = thickness of the toroid region swept by the blades in the axial direction

W_{fan} = fan power

r = local radial distance from the fan axis

$\Omega_{operating}$ = fan operating angular velocity

R_h = radius of the fan hub

R_{ip} = radius of a point on the fan blade based on the inflection point ratio

R_t = radius of the fan blade tip

ρ = fluid density

V_ϕ = local tangential velocity

In order to calculate the tangential source, three other expressions are necessary:

$$W_{fan} = (\mathbf{v}_{exit} \cdot \mathbf{a}_{exit}) \Delta P(Q) \tag{7.60}$$

$$R_{ip} = R_h + (R_t - R_h) b_{ip} \tag{7.61}$$

$$c_1 = \pi h \left(R_{ip}^2 \left(2R_t^2 - R_{ip}^2 \right) - R_h^4 \right) \tag{7.62}$$

where

$\mathbf{v}_{exit}$ = velocity vector at the fan exit plane

$\mathbf{a}_{exit}$ = area vector at the fan exit plane

b_{ip} = the inflection point ratio, that is, the fraction of the fan blade length (starting at the hub) over which the tangential velocity of the fan discharge is increasing with increasing radius and peaks, before tapering off (see Figure 7.30: The Inflection Point Ratio of a Pitched Blade Turbine (p. 1354))

The pressure rise across the 3D fan zone is specified as a function of the volumetric flow rate through the fan. The relationship may be a constant or a fan curve, that is, a polynomial or piecewise-linear function. In the case of a polynomial, the relationship is of the form

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\Delta P(Q) = \sum_{n=1}^{N} f_n Q^{n-1} \tag{7.63}$$

where f_n are the pressure head polynomial coefficients (calculated by Fluent), and Q is the flow rate normal to the fan.

Important:

The flow rate Q can be either positive or negative. You must be careful to model the fan so that a pressure rise occurs for forward flow through the fan.

The fan curve data is typically collected at a prescribed set of test conditions. However, the operating conditions of your CFD simulation may be inconsistent with this data (for example, the rotational speed or fluid temperature may be different). To account for this, the 3D fan model can adjust the fan curve data according to the following scaling relationships:

$$P_{\text{operating}}(Q) = P_{\text{test}}(Q)\sqrt{\frac{\Omega_{\text{operating}}}{\Omega_{\text{test}}}} \tag{7.64}$$

$$Q_{\text{operating}} = Q_{\text{test}}\sqrt{\frac{\Omega_{\text{operating}}}{\Omega_{\text{test}}}} \tag{7.65}$$

$$W_{\text{fan,operating}} = W_{\text{fan,test}}\frac{T_{\text{test}}}{T_{\text{avg}}} \tag{7.66}$$

where T_{test} and T_{avg} are the test temperature and the volume-averaged temperature of the fan cell zone (which is calculated internally), respectively.

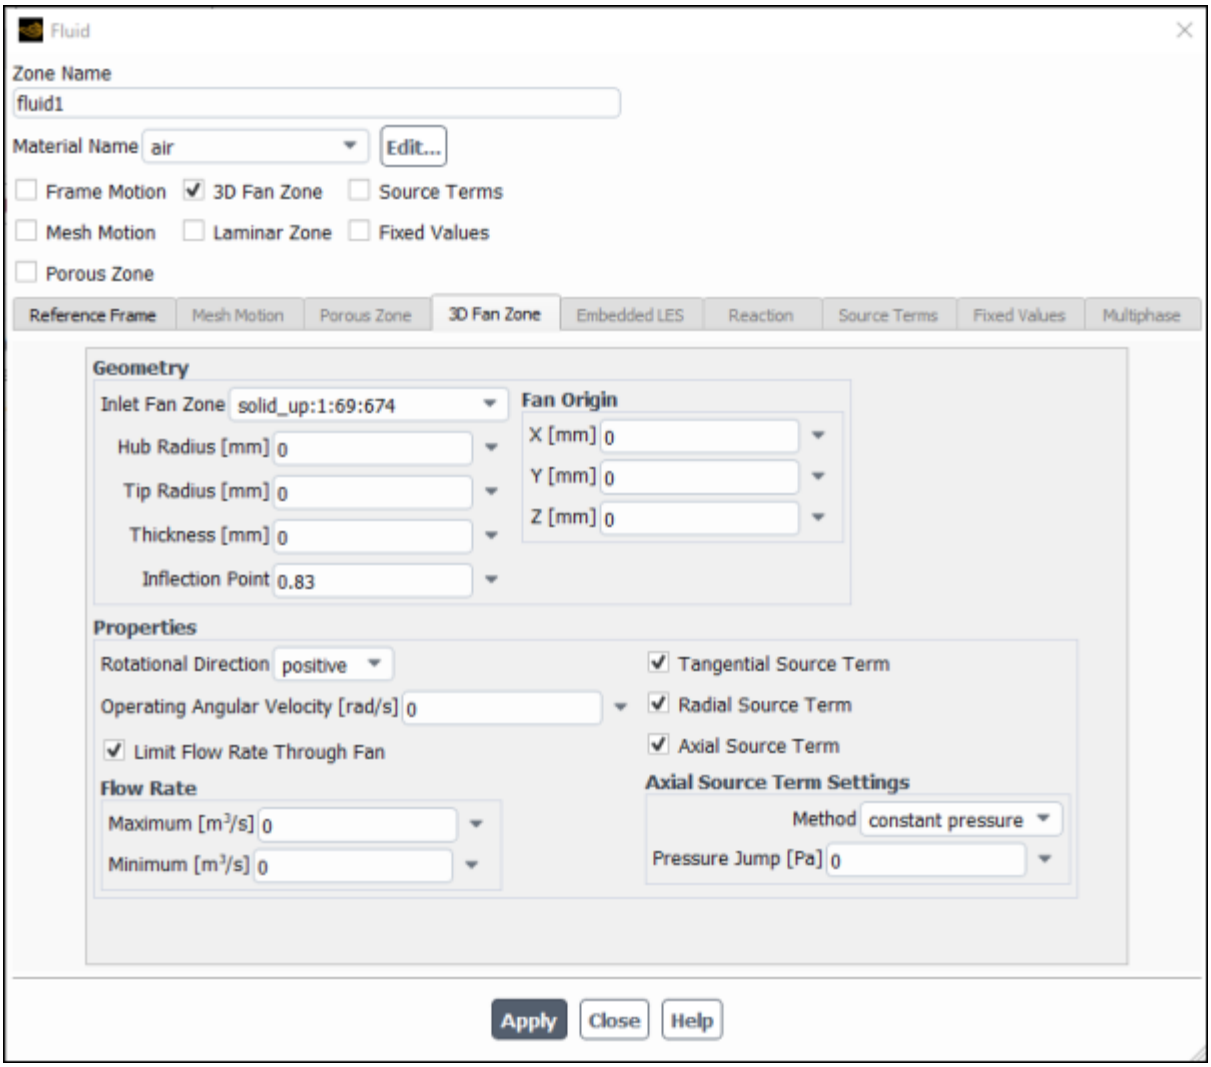
7.2.4.2. User Inputs for 3D Fan Zones

A 3D fan zone is modeled as a special type of fluid zone. The cell zone should have a toroid shape that is sized to match the blade-swept volume of the fan you are simulating (that is, has an inner and outer radius that matches the radius of the fan's hub and blade tips, respectively, as well as a length that matches the thickness of the toroid region swept by the blades in the axial direction). Furthermore, the fluid cell zone should be "interior", that is, have at least two boundary zones of type **interior** that border another fluid cell zone and act as the fan inlet and outlet (the other boundaries can be of type **interior** as well).

To designate a cell zone as a 3D fan zone, enable the **3D Fan Zone** option in the **Fluid** dialog box and then define the geometry and properties of the fan in the **3D Fan Zone** tab.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.29: The Fluid Dialog Box for a 3D Fan Zone



7.2.4.2.1. Defining the Geometry of a 3D Fan Zone

After enabling the **3D Fan Zone** option in the **Fluid** dialog box, you can begin setting it up by defining the settings in the **Geometry** group box in the **3D Fan Zone** tab of the fluid cell zone:

1. Select a boundary zone from the **Inlet Fan Zone** drop-down list, which will act as the inlet zone for the 3D fan zone and the surface on which the fan will be located. This boundary must meet certain requirements: it must be of type **interior**; it must be planar; and it must act as a boundary between the 3D fan zone and another fluid cell zone. Note that the direction the fan blows will be *into* the 3D fan zone, perpendicular to this boundary zone.

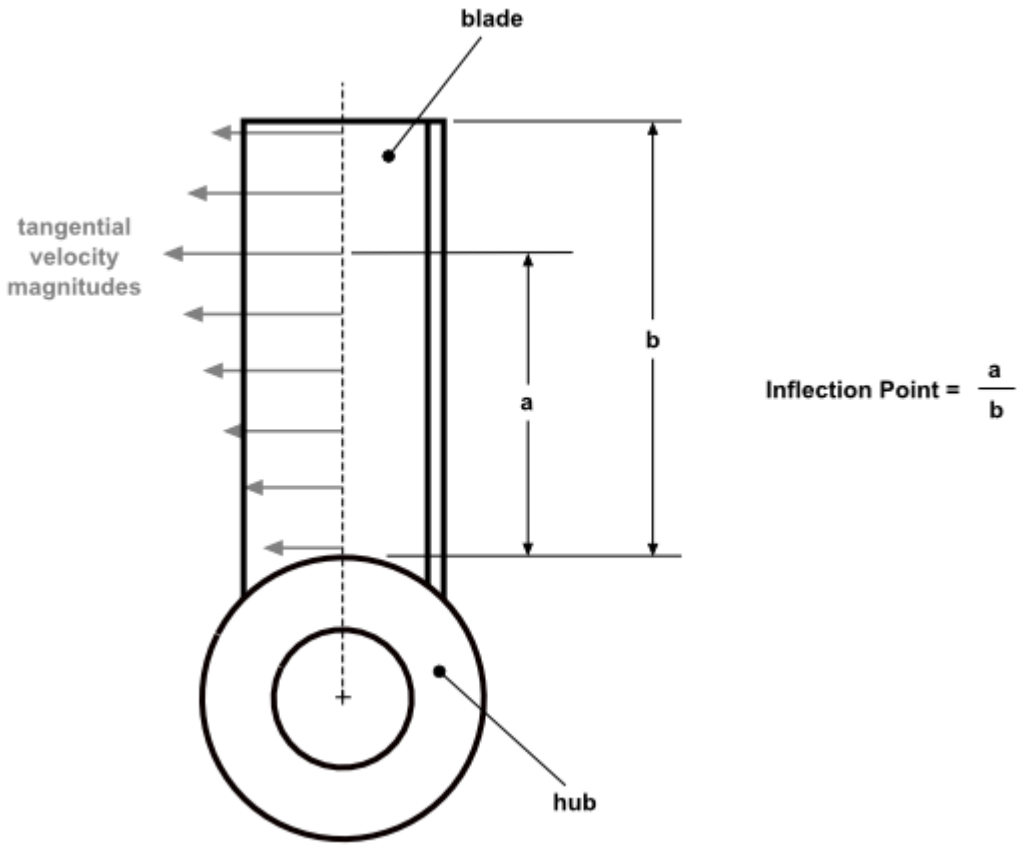
2. Define the overall dimensions of the fan by entering values for the **Hub Radius** and the **Tip Radius**, as well as the **Thickness** of the toroid region swept by the blades in the axial direction. Note that the values must fit within the confines of the 3D fan zone, and that the **Thickness** will be applied from the **Inlet Fan Zone** into the 3D fan zone.

3. Specify the **Inflection Point** ratio. The inflection point ratio represents the fraction of the fan blade length (starting at the hub) over which the tangential velocity of the fan discharge is increasing with increasing radius and peaks, before tapering off. See Figure 7.30: The Inflec-

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

tion Point Ratio of a Pitched Blade Turbine (p. 1354) for an illustration. You can derive this ratio empirically from experimental data; otherwise, you can first use Ansys Fluent to model the actual fan geometry (for example, using a moving reference frame simulation) and then use those results to determine the input parameters for simpler simulations using the **3D Fan Zone** option.

Figure 7.30: The Inflection Point Ratio of a Pitched Blade Turbine



4. Enter the coordinates for the **Fan Origin**. This must define a point that is on the plane of the **Inlet Fan Zone** and located such that the diameters of the fan fall within boundaries of the **Inlet Fan Zone**.

7.2.4.2.2. Defining the Properties of a 3D Fan Zone

To complete the setup of a 3D fan zone, you must define the settings in the **Properties** group box in the **3D Fan Zone** tab of the fluid cell zone:

1. Define the **Rotational Direction** of the fan. The rotation is deemed **positive** if it follows the right-hand rule with respect to the fan direction vector (that is, a vector from the **Fan Origin** that points into the 3D fan zone perpendicular to the **Inlet Fan Zone**).

2. Specify the **Operating Angular Velocity** of the fan. This must be a positive nonzero number.

3. You can enable the **Limit Flow Rate Through Fan** option, and thereby specify the **Maximum** and **Minimum** flow rates that are allowed.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. You can enable the **Tangential Source Term**, **Radial Source Term**, and/or **Axial Source Term** options, in order to enable momentum sources in the specified directions. Note that the tangential and radial sources are defined according to impeller theory, and so no further inputs are necessary, whereas the axial source term requires additional input (as described in the step that follows).

5. If you have enabled the **Axial Source Term** option, you must define this source in the **Axial Source Term Settings** group box. For the **Method**, you can select one of the following choices:

   - **constant pressure**

     With this method, you must then specify a constant **Pressure Jump** that is applied to all of the cells in the 3D fan zone.

   - **fan curve**

     This method allows you to specify the pressure jump through a fan curve (pressure rise vs. volumetric flow rate). Using the **Read Fan Curve...** button, you can read in a tab-delimited ASCII file that defines the relationship between pressure and flow rate for the 3D fan cell zone (see 3D Fan Curve File Format (p. 5636) for details). You must then specify the **Curve Fitting Method** Fluent should use on the data points in your file, selecting either **polynomial** or **piecewise-linear** (for the former, you must then define the **Order of Polynomial**). Finally, you must provide an estimate of the **Initial Flow Rate** through your fan zone, as well as the **Test Angular Velocity** and **Test Temperature** of the experiment that produced the data points.

     Note that a single file can define multiple cell zones, but the file must be read in each of the applicable **Fluid** dialog boxes.

7.2.4.3. 3D Fan Zone Limitations

Note the following limitations when setting up a 3D fan zone:

- 3D fan zones are not supported with the premixed combustion model.
- 3D fan zones are not supported with the Eulerian multiphase model.
- The **Energy Equation** must be enabled in the Energy Dialog Box (p. 4662) for 3D fan zones when **fan curve** is selected for the axial source term method.

7.2.5. Fixing the Values of Variables

The option to fix values of variables in Ansys Fluent allows you to set the value of one or more variables in a fluid or solid zone, essentially setting a boundary condition for the variables within the cells of the zone. When a variable is fixed in a given cell, the transport equation for that variable is not solved in the cell (and the cell is not included when the residual sum is computed for that variable). The

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

fixed value is used for the calculation of face fluxes between the cell and its neighbors. The result is a smooth transition between the fixed value of a variable and the values at the neighboring cells.

Important:

You can fix values for temperature, species mass fractions, and/or velocity components only if you are using the pressure-based solver. (Refer to Pressure-Based Solver in the Theory Guide for information about the pressure-based solver.)

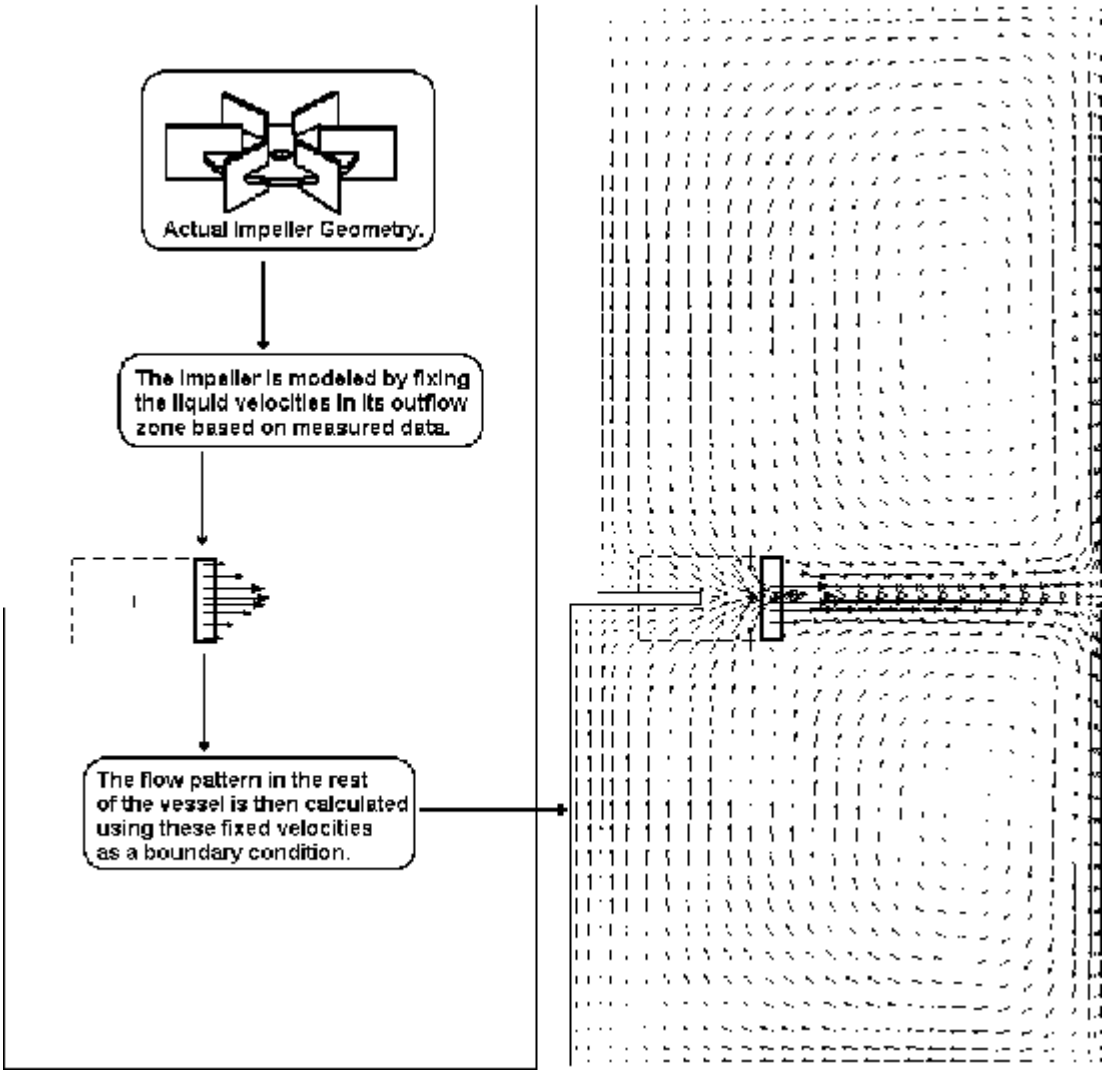
7.2.5.1. Overview of Fixing the Value of a Variable

The ability to fix the value of a variable has a wide range of applications. The velocity fixing method is often used to model the flow in stirred tanks. This approach provides an alternative to the use of a moving reference frame (solution in the reference frame of the blade) and can be used to model baffled tanks. In both 2D and 3D geometries, a fluid cell zone may be used in the impeller regions, and velocity components can be fixed based on measured data.

Although the actual impeller geometry can be modeled and the flow pattern calculated using the sliding mesh model, experimental data for the velocity profile in the outflow region are available for many impeller types. If you do not need to know the details of the flow around the blades for your problem, you can model the impeller by fixing the experimentally-obtained liquid velocities in its outflow zone. The velocities in the rest of the vessel can then be calculated using this fixed velocity profile as a boundary condition. Figure 7.31: Fixing Values for the Flow in a Stirred Tank (p. 1357) shows an example of how this method is used to model the flow pattern created by a disk-turbine in an axisymmetric stirred vessel.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.31: Fixing Values for the Flow in a Stirred Tank



7.2.5.1.1. Variables That Can Be Fixed

The variables that can be fixed include velocity components (pressure-based solver only), turbulence quantities, temperature (pressure-based solver only), enthalpy, species mass fractions (pressure-based solver only), and user-defined scalars. For turbulence quantities, different values can be set depending on your choice of turbulence model. You can fix the value of the temperature in a fluid or solid zone if you are solving the energy equation. If you are using the non-premixed combustion model, you can fix the enthalpy in a fluid zone. If you have more than one species in your model, you can specify fixed values for the species mass fractions for each individual species except the last one you defined. See the Fluent Customization Manual for details about defining user-defined scalars.

If you are using the Eulerian multiphase model, you can fix the values of velocity components and (depending on which multiphase turbulence model you are using) turbulence quantities on a per-phase basis. See Eulerian Model (p. 2964) for details about setting boundary conditions for Eulerian multiphase calculations.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.2.5.2. Procedure for Fixing Values of Variables in a Zone

To fix the values of one or more variables in a cell zone, follow these steps (remembering to use only SI units):

1. In the Fluid Dialog Box (p. 4909) or Solid Dialog Box (p. 4921), enable the **Fixed Values** option.

2. Fix the values for the appropriate variables in the **Fixed Values** tab, noting the comments below.

   - To specify a constant value for a variable, choose **constant** in the drop-down list next to the relevant field and then enter the constant value in the field.

   - To specify a non-constant value for a variable, you can use a profile (see Profiles (p. 1540)) or a user-defined function for a profile (see the Fluent Customization Manual). Select the appropriate profile or UDF in the drop-down list next to the relevant field.

     If you specify a radial-type profile (see Profile Specification Types (p. 1540)) for temperature, enthalpy, species mass/mole fractions, or turbulence quantities for the k - ε, Spalart-Allmaras, or k - ω model, the local coordinate system upon which the radial profile is based is defined by the **Rotation-Axis Origin** and **Rotation-Axis Direction** for the fluid zone. See Specifying the Rotation Axis (p. 1301) for information about setting these parameters. (Note that it is acceptable to specify the rotation axis and direction for a non-rotating zone. This will not cause the zone to rotate; it will not rotate unless it has been explicitly defined as a moving zone.)

   - If you do not want to fix the value for a variable, choose (or keep) **none** in the drop-down list next to the relevant field. This is the default for all variables.

7.2.5.2.1. Fixing Velocity Components

To fix the velocity components, you can specify **X**, **Y**, and (in 3D) **Z Velocity** values, or, for axisymmetric cases, **Axial**, **Radial**, and (for axisymmetric swirl) **Swirl Velocity** values. The units for a fixed velocity are m/s.

For 3D cases, you can choose to specify cylindrical velocity components instead of Cartesian components. Turn on the **Local Coordinate System For Fixed Velocities** option, and then specify the **Axial**, **Radial**, and/or **Tangential Velocity** values. The local coordinate system is defined by the **Rotation-Axis Origin** and **Rotation-Axis Direction** for the fluid zone. See Specifying the Rotation Axis (p. 1301) for information about setting these parameters. (Note that it is acceptable to specify the rotation axis and direction for a non-rotating zone. This will not cause the zone to rotate; it will not rotate unless it has been explicitly defined as a moving zone.)

Important:

Note the following:

- You can fix values for velocity components only if you are using the pressure-based solver. (Refer to Pressure-Based Solver in the Theory Guide for information about the pressure-based solver.)

- If all components of velocity are set to fixed values, the solver will also set the gauge pressure to zero on all cells in the cell zone.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.2.5.2.2. Fixing Temperature and Enthalpy

If you are solving the energy equation, you can fix the temperature in a zone by specifying the value of the **Temperature**. The units for a fixed temperature are K.

If you are using the non-premixed combustion model, you can fix the enthalpy in a zone by specifying the value of the **Enthalpy**. The units for a fixed enthalpy are J/kg.

If you specify a radial-type profile (see Profile Specification Types (p. 1540)) for temperature or enthalpy, the local coordinate system upon which the radial profile is based is defined by the **Rotation-Axis Origin** and **Rotation-Axis Direction** for the fluid zone. See above for details.

Important:

You can fix the value of temperature only if you are using the pressure-based solver.

7.2.5.2.3. Fixing Species Mass Fractions

If you are using the species transport model, you can fix the values of the species mass fractions for individual species. Ansys Fluent allows you to fix the species mass fraction for each species (for example, **h2**, **o2**) except the last one you defined.

If you specify a radial-type profile (see Profile Specification Types (p. 1540)) for a species mass fraction, the local coordinate system upon which the radial profile is based is defined by the **Rotation-Axis Origin** and **Rotation-Axis Direction** for the fluid zone. See above for details.

Important:

You can fix values for species mass fractions only if you are using the pressure-based solver.

7.2.5.2.4. Fixing Turbulence Quantities

To fix the values of k and ε in the k - ε equations, specify the **Turbulence Kinetic Energy** and **Turbulence Dissipation Rate** values. The units for k are m^2/s^2 and those for ε are m^2/s^3.

To fix the value of the modified turbulent viscosity ($\tilde{\nu}$) for the Spalart-Allmaras model, specify the **Modified Turbulent Viscosity** value. The units for the modified turbulent viscosity are m^2 /s.

To fix the values of k and ω in the k - ω equations, specify the **Turbulence Kinetic Energy** and **Specific Dissipation Rate** values. The units for k are m^2/s^2 and those for ω are 1/s.

To fix the value of k, ε, or the Reynolds stresses in the RSM transport equations, specify the **Turbulence Kinetic Energy**, **Turbulence Dissipation Rate**, **Specific Dissipation Rate**, **UU Reynolds Stress**, **VV Reynolds Stress**, **WW Reynolds Stress**, **UV Reynolds Stress**, **VW Reynolds Stress**, and/or **UW Reynolds Stress**. The units for k and the Reynolds stresses are m^2/s^2, and those for ε are m^2/s^3.

If you specify a radial-type profile (see Profile Specification Types (p. 1540)) for k, ε, ω, or $\tilde{\nu}$, the local coordinate system upon which the radial profile is based is defined by the **Rotation-Axis**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Origin and **Rotation-Axis Direction** for the fluid zone. See above for details. Note that you cannot specify radial-type profiles for the Reynolds stresses.

7.2.5.2.5. Fixing User-Defined Scalars

To fix the value of a user-defined scalar, specify the **User-defined scalar-n** value. (There will be one for each user-defined scalar you have defined.) The units for a user-defined scalar will be the appropriate SI units for the scalar quantity. See the Fluent Customization Manual for information on user-defined scalars.

7.2.6. Locking the Temperature for Solid and Shell Zones

You can lock (or "freeze") the temperature values for all the cells in solid zones (including cells to which you have applied an energy source using a UDF) and in walls that have shell conduction enabled, so that the values do not change during further solver iterations. When the temperature is locked for a given cell, the transport equation will still be solved in the cell, and the cell will be included when the residual sum is computed.

You can lock / unlock the temperature for solid and shell zones by using the following text command:

`solve → set → lock-solid-temperature?`

Note the following about the option for locking the temperature of solid and shell zones:

- It is only available when energy is enabled and the pressure-based solver is selected.
- When this option is used, the **BCGSTAB** option from the **Stabilization Method** drop-down list of the **Advanced Solution Controls** dialog box is not supported.
- Alternative means of monitoring the convergence of energy may be used.

7.2.7. Defining Mass, Momentum, Energy, and Other Sources

You can define volumetric sources of mass (for single or multiple species), momentum, energy, turbulence, and other scalar quantities in a fluid zone, or a source of energy for a solid zone. This feature is useful when you want to input a known value for these sources. (For more complicated sources with functional dependency, you can create a user-defined function as described in the separate Fluent Customization Manual.) To add source terms to a cell or group of cells, you must place the cell(s) in a separate zone. The sources are then applied to that cell zone. Typical uses for this feature are listed below:

- A flow source that cannot be represented by an inlet, for example, due to an issue of scale. If you need to model an inlet that is smaller than a cell, you can place the cell where the tiny "inlet" is located in its own fluid zone and then define the mass, momentum, and energy sources in that cell zone. For the example shown in Figure 7.32: Defining a Source for a Tiny Inlet (p. 1361), you should set a mass source of $\frac{\dot{m}}{V} = \frac{\rho_j A_j v_j}{V}$ and a momentum source of $\frac{\dot{m}v}{V} = \frac{\dot{m}v_j}{V}$, where V is the cell volume.
- Heat release due to a source (for example, fire) that is not explicitly defined in your model. For this case, you can place the cell(s) into which the heat is originally released in its own fluid zone and then define the energy source in that cell zone.

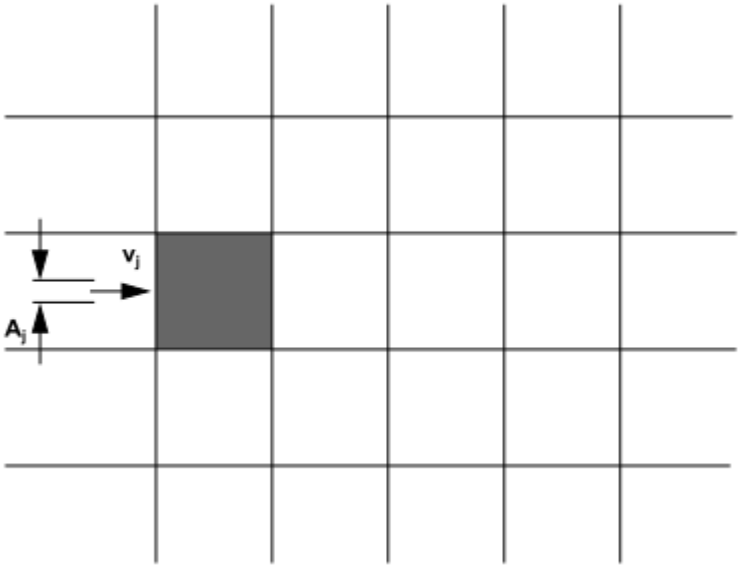
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- An energy source in a solid zone, for conjugate heat transfer applications. For this case, you can place the cell(s) into which the heat is originally released in its own solid zone and then define the energy source in that cell zone.
- A species source due to a reaction that is not explicitly included in the model. In the above example of simulating a fire, you might need to define a source for a species representing smoke generation.

Important:

Note that if you define a mass source for a cell zone, you should also define a momentum source and, if appropriate for your model, energy and turbulence sources. If you define only a mass source, that mass will assume the velocity, temperature/enthalpy of the corresponding cell. The mass will therefore have to be accelerated and heated by the flow and, consequently, there may be a drop in velocity or temperature. This drop may or may not be perceptible, depending on the size of the source. (Note that defining only a momentum, energy, or turbulence source is acceptable.)

Figure 7.32: Defining a Source for a Tiny Inlet



7.2.7.1. Sign Conventions and Units

All positive source terms indicate sources, and all negative source terms indicate sinks. All sources must be specified in SI units.

7.2.7.2. Procedure for Defining Sources

To define one or more source terms for a zone, follow these steps (remembering to use only SI units):

1. In the Fluid Dialog Box (p. 4909) or Solid Dialog Box (p. 4921), turn on the **Source Terms** option.
2. Set the appropriate source terms under the **Source Terms** tab, noting the comments below.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- To specify a source, click the **Edit...** button next to the mass, momentum, energy, or other source. The sources dialog box will open where you will define the number of sources. For each source, choose **none**, **constant**, or **New Input Parameter...** in the drop-down list.
- If you do not want to specify a source term for a variable, choose (or keep) **none** in the drop-down list next to the relevant field. This is the default for all variables.
- To specify a constant source, choose **constant** in the drop-down list and then enter the constant value in the field.
- To specify a new source parameter, choose **New Input Parameter...** in the drop-down list and enter the **Name** or the parameter and the **Current Value** as a constant.
- It is not recommended to only define a mass source without defining the other sources, as described in Defining Mass, Momentum, Energy, and Other Sources (p. 1360) above.
- Since the sources you specify are defined per unit volume, to determine the appropriate value of your source term you will often need to first determine the volume of the cell(s) in the zone for which you are defining the source. To do this, you can use the Volume Integrals Dialog Box (p. 5275).
- In this guide, source is used as a generic term for both source and sink; where source means addition, and sink means subtraction to the physics model. Addition of a source usually leads to the opposite outcome of a sink. For example, a momentum source will accelerate the flow, and in contrast, a momentum sink will decelerate the flow. In general, a source term can be replaced with a sink term with opposite expected outcome.

More details are discussed in the sections that follow.

7.2.7.2.1. Mass Sources

7.2.7.2.2. Momentum Sources

7.2.7.2.3. Energy Sources

7.2.7.2.4. Turbulence Sources

7.2.7.2.5. Mean Mixture Fraction and Variance Sources

7.2.7.2.7. Progress Variable Sources

7.2.7.2.8. NO, HCN, and NH3 Sources for the NOx Model

7.2.7.2.9. Discrete Bin Fraction Sources for the Population Balance Model

7.2.7.2.10. User-Defined Scalar (UDS) Sources

7.2.7.2.1. Mass Sources

If you have only one species in your problem, you can simply define a **Mass** source for that species. The units for the mass source are $kg/m^3–s$. In the continuity equation (Equation 1.1 in the Theory Guide), the defined mass source will appear in the S_m term.

If you have more than one species, you can specify mass sources for each individual species. There will be a total **Mass** source term as well as a source term listed explicitly for each species (for example, **h2**, **o2**) except the last one you defined. If the total of all species mass sources (including the last one) is 0, then you should specify a value of 0 for the **Mass** source, and also

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

specify the values of the nonzero individual species mass sources. Since you cannot specify the mass source for the last species explicitly, Ansys Fluent will compute it by subtracting the sum of all other species mass sources from the specified total **Mass** source.

For example, if the mass source for hydrogen in a hydrogen-air mixture is 0.01, the mass source for oxygen is 0.02, and the mass source for nitrogen (the last species) is 0.015, you will specify a value of 0.01 in the **h2** field, a value of 0.02 in the **o2** field, and a value of 0.045 in the **Mass** field. This concept also applies within each cell if you use user-defined functions for species mass sources.

The units for the species mass sources are kg/m^3–s. In the conservation equation for a chemical species (Equation 7.1 in the Theory Guide), the defined mass source will appear in the S_i term.

Note:

When a mass source is added in the continuity equation, a corresponding energy source is added in the energy equation at a reference temperature of 0 K for inviscid flows and 298.15 K for viscous flows.

7.2.7.2.2. Momentum Sources

To define a source of momentum, specify the **X Momentum**, **Y Momentum**, and/or **Z Momentum** term. The units for the momentum source are N/ m^3. In the momentum equation (Equation 1.3 in the Theory Guide), the defined momentum source will appear in the $\vec{F}$ term.

7.2.7.2.3. Energy Sources

To define a source of energy, specify an **Energy** term. The units for the energy source are W/ m^3. In the energy equation (Equation 5.1 in the Theory Guide), the defined energy source will appear in the S_h term.

7.2.7.2.4. Turbulence Sources

7.2.7.2.4.1. Turbulence Sources for the k-ε Model

To define a source of k or ε in the k - ε equations, specify the **Turbulent Kinetic Energy** or **Turbulent Dissipation Rate** term. The units for the k source are kg/m- s^3 and those for ε are kg/m- s^4.

The defined k source will appear in the S_k term on the right-hand side of the turbulent kinetic energy equation (for example, Equation 4.39 in the Theory Guide).

The defined ε source will appear in the S_ε term on the right-hand side of the turbulent dissipation rate equation (for example, Equation 4.40 in the Theory Guide).

7.2.7.2.4.2. Turbulence Sources for the Spalart-Allmaras Model

To define a source of modified turbulent viscosity, specify the **Modified Turbulent Viscosity** term. The units for the modified turbulent viscosity source are kg/m- s^2. In the transport equation for the Spalart-Allmaras model (Equation 4.15 in the Theory Guide), the defined modified turbulent viscosity source will appear in the $S_{\tilde{\nu}}$ term.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.2.7.2.4.3. Turbulence Sources for the k- ω Model

To define a source of k or ω in the k - ω equations, specify the **Turbulent Kinetic Energy** or **Specific Dissipation Rate** term. The units for the k source are kg/m- s^3 and those for ω are kg/ m^3 - s^2.

The defined k source will appear in the S_k term on the right-hand side of the turbulent kinetic energy equation (Equation 4.71 in the Theory Guide).

The defined ω source will appear in the S_ω term on the right-hand side of the specific turbulent dissipation rate equation (Equation 4.72 in the Theory Guide).

7.2.7.2.4.4. Turbulence Sources for the Reynolds Stress Model

To define a source of k, ε, or the Reynolds stresses in the RSM transport equations, specify the **Turbulence Kinetic Energy**, **Turbulence Dissipation Rate**, **Specific Dissipation Rate**, **UU Reynolds Stress**, **VV Reynolds Stress**, **WW Reynolds Stress**, **UV Reynolds Stress**, **VW Reynolds Stress**, and/or **UW Reynolds Stress** terms. The units for the k source and the sources of Reynolds stress are kg/m- s^3, and those for ε are kg/m- s^4.

The defined Reynolds stress sources will appear in the S_{user} term on the right-hand side of the Reynolds stress transport equation (Equation 4.226 in the Theory Guide).

The defined k source will appear in the S_k term on the right-hand side of Equation 4.254 in the Theory Guide.

The defined ε will appear in the S_ε term on the right-hand side of Equation 4.257 in the Theory Guide.

7.2.7.2.5. Mean Mixture Fraction and Variance Sources

To define a source of the mean mixture fraction or its variance for the non-premixed combustion model, specify the **Mean Mixture Fraction** or **Mixture Fraction Variance** term. The units for the mean mixture fraction source are kg/m^3–s, and those for the mixture fraction variance source are kg/m^3–s.

The defined mean mixture fraction source will appear in the S_{user} term in the transport equation for the mixture fraction (Equation 8.4 in the Theory Guide).

The defined mixture fraction variance source will appear in the S_{user} term in the transport equation for the mixture fraction variance (Equation 8.5 in the Theory Guide).

If you are using the two-mixture-fraction approach, you can also specify sources of the **Secondary Mean Mixture Fraction** and **Secondary Mixture Fraction Variance**.

7.2.7.2.6. P-1 Radiation Sources

To define a source for the P-1 radiation model, specify the **P1** term. The units for the radiation source are W/ m^3, and the defined source will appear in the S_G term in Equation 5.57 in the Theory Guide.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note that, if the source term you are defining represents a transfer from internal energy to radiative energy (for example, absorption or emission), you must specify an **Energy** source of the same magnitude as the **P1** source, but with the opposite sign, in order to ensure overall energy conservation.

7.2.7.2.7. Progress Variable Sources

To define a source of the progress variable for the premixed combustion model, specify the **Progress Variable** term. The units for the progress variable source are kg/ m^3 -s, and the defined source will appear in the ρS_c term in Equation 8.70 in the Theory Guide.

7.2.7.2.8. NO, HCN, and NH3 Sources for the NOx Model

To define a source of NO, HCN, or NH_3 for the NOx model, specify the **no**, **hcn**, or **nh3** term. The units for these sources are kg/ m^3 -s, and the defined sources will appear in the S_{NO}, S_{HCN}, and S_{NH3} terms of Equation 9.1, Equation 9.2, and Equation 9.3 in the Theory Guide.

7.2.7.2.9. Discrete Bin Fraction Sources for the Population Balance Model

For the **Discrete** and **Inhomogeneous Discrete** population balance models, you can specify **Bin-*i*-fraction** source terms (where i is the bin label). Note that bins are labeled from 0 to $N-1$, where N is the number of bins that you specified in the **Population Balance Model** tab of the **Multiphase Model** dialog box. The units for the fraction source are kg/m^3 s.

7.2.7.2.10. User-Defined Scalar (UDS) Sources

You can specify source term(s) for each UDS transport equation you have defined in your model. See Setting Up UDS Equations in Ansys Fluent (p. 1711) for details.

7.3. Operating Conditions

7.3.1. Buoyancy-Driven Flows and Natural Convection

A buoyancy-driven flow is induced due to the force of gravity acting on the density variations. When the density variation is caused by temperature, such buoyancy-driven flows are termed as natural convection flows.

For more information about the theory behind natural convection and buoyancy-driven flows, see Natural Convection and Buoyancy-Driven Flows Theory in the Theory Guide.

7.3.1.1. Modeling Natural Convection in a Closed Domain

When you model natural convection inside a closed domain, the solution will depend on the mass inside the domain. Since this mass will not be known unless the density is known, you must model the flow in one of the following ways:

- Perform a transient calculation. In this approach, the initial density will be computed from the initial pressure and temperature, so the initial mass is known. As the solution progresses over time, this mass will be properly conserved. If the temperature differences in your domain are large, you must follow this approach.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Perform a steady-state calculation using the Boussinesq model (described in The Boussinesq Model (p. 1366)). In this approach, you will specify a constant density, so the mass is properly specified. This approach is valid only if the temperature differences in the domain are small. If not, you use the transient approach.

  Important:

  For a closed domain, you can use the *incompressible* ideal gas law only with a *fixed* operating pressure. It *cannot* be used with a floating operating pressure. You can use the *compressible* ideal or real gas law with either *floating* or *fixed* operating pressure.

See Floating Operating Pressure (p. 1735) for more information about the floating operating pressure option.

7.3.1.2. The Boussinesq Model

For many natural-convection flows, you can get faster convergence with the Boussinesq model than you can get by setting up the problem with fluid density as a function of temperature. This model treats density as a constant value in all solved equations, except for the buoyancy term in the momentum equation:

$$\left(\rho-\rho_0\right)g \approx -\rho_0\beta\left(T-T_0\right)g \tag{7.67}$$

where ρ_0 is the (constant) density of the flow, T_0 is the operating temperature, and β is the thermal expansion coefficient. Equation 7.67 (p. 1366) is obtained by using the Boussinesq approximation $\rho=\rho_0\left(1-\beta\Delta T\right)$ to eliminate ρ from the buoyancy term. This approximation is accurate as long as changes in actual density are small; specifically, the Boussinesq approximation is valid when $\beta\left(T-T_0\right)\ll 1$.

7.3.1.3. Limitations of the Boussinesq Model

The Boussinesq model should not be used if the temperature differences in the domain are large. In addition, it cannot be used with species calculations, combustion, or reacting flows.

7.3.1.4. Steps in Solving Buoyancy-Driven Flow Problems

The procedure for including buoyancy forces in the simulation of mixed or natural convection flows is described below.

1. To activate the calculation of heat transfer, enable the energy equation by right-clicking **Energy** in the tree (under **Setup/Models**) and clicking **On** in the menu that opens (Figure 15.1: Enabling the Energy Equation (p. 2128)).

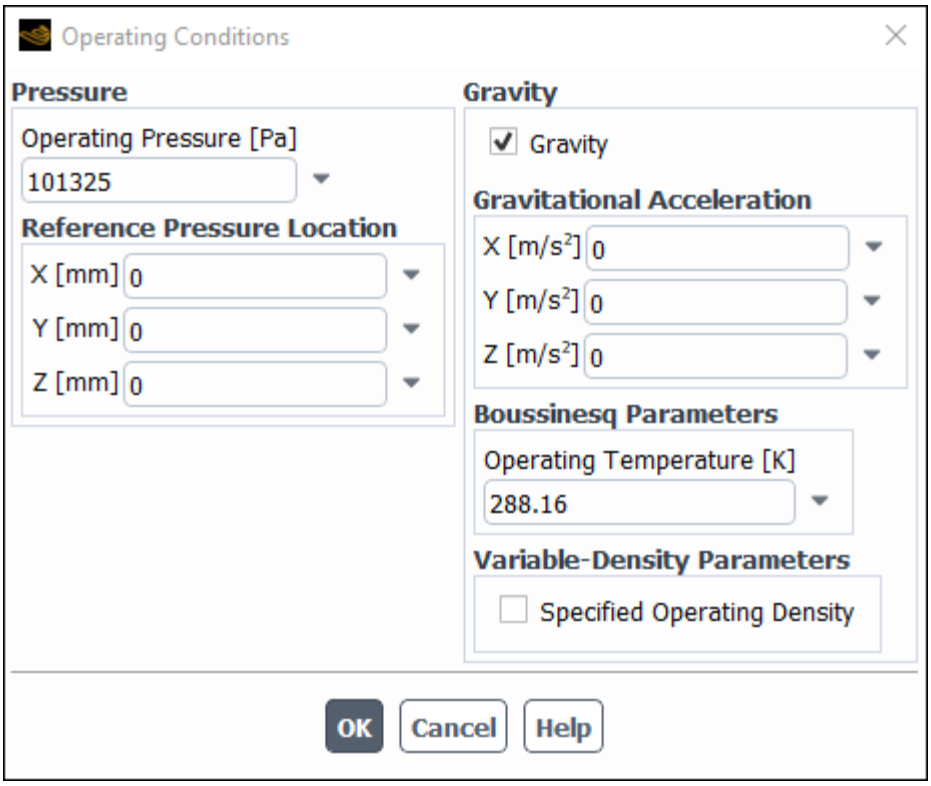
   Setup → **Models** → **Energy** → **On**

2. Define the operating conditions in the **Operating Conditions** dialog box (Figure 7.33: The Operating Conditions Dialog Box (p. 1367)).

   Setup → **Cell Zone Conditions** → **Operating Conditions...**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.33: The Operating Conditions Dialog Box



a. Enable the **Gravity** option under **Gravity**.

b. Enter the appropriate values in the **X**, **Y**, and (for 3D) **Z** fields for **Gravitational Acceleration** for each Cartesian coordinate direction. (Note that the default gravitational acceleration in Ansys Fluent is zero.)

c. If you are using the incompressible ideal gas law, check that the **Operating Pressure** is set to an appropriate (nonzero) value.

d. Depending on whether or not you use the Boussinesq approximation, specify the appropriate parameters described below:

   - If you are not using the Boussinesq model, the inputs are as follows:

     i. If necessary, define the operating density:

        – For a single-phase flow, enable the **Specified Operating Density** option in the **Operating Conditions** dialog box, and enter a value for the **Operating Density**. See below for details.

> **Note:**
>
> For compressible (ideal and real) gas models with buoyancy, you should specify a value of zero for **Operating Density**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

– For a multiphase flow, Ansys Fluent uses the **minimum-phase-averaged** operating density method by default. If you want to provide your own input, select the **user-input** method from the **Operating Density** drop-down list in the **Operating Conditions** dialog box (**Variable-Density Parameters** group box) and enter the value of the operating density. See Setting the Operating Density for a Buoyancy-Driven Multiphase Flow (p. 2926) for details.

ii. Define the fluid density as a function of temperature as described in Defining Properties Using Temperature-Dependent Functions (p. 1590) and Density (p. 1598).

Setup → **Materials**

- If you are using the Boussinesq model (described in The Boussinesq Model (p. 1366)) the inputs are as follows:

i. Enter the **Operating Temperature** (T_0 in Equation 7.67 (p. 1366)) in the **Operating Conditions** dialog box.

ii. Select **boussinesq** in the drop-down list for **Density** in the **Create/Edit Materials** dialog box as described in Defining Properties Using Temperature-Dependent Functions (p. 1590) and Density (p. 1598), and enter a constant value.

iii. Also in the **Create/Edit Materials** dialog box, enter an appropriate value for the **Thermal Expansion Coefficient** (β in Equation 7.67 (p. 1366)) for the fluid material.

Note that if your model involves multiple fluid materials you can choose whether or not to use the Boussinesq model for each material. As a result, you may have some materials using the Boussinesq model and others not. In such cases, you will need to set all the parameters described above in this step.

3. Define the boundary conditions. The boundary condition dialog boxes can be opened by right-clicking the boundary name in the tree (under **Setup/Boundary Conditions**) and clicking **Edit...** in the menu that opens; alternatively, you can open them from the **Boundary Conditions** task page:

Setup → **Boundary Conditions**

The boundary pressures that you specify at pressure inlet and outlet boundaries are the redefined pressures as given by Equation 7.68 (p. 1369). In general you should enter equal pressures, p', at the inlet and exit boundaries of your Ansys Fluent model if there are no externally imposed pressure gradients.

4. Set the parameters that control the solution, using the **Solution Methods** task page.

Solution → **Methods**

a. If you are using the pressure-based solver, selecting **PRESTO!** for **Pressure** under **Spatial Discretization** is recommended.

b. Add cells near the walls to resolve boundary layers, if necessary.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

See also Solving Heat Transfer Problems (p. 2128) for information on setting up heat transfer calculations.

7.3.1.5. If you are using the incompressible ideal gas law, check the Operating Density

When the Boussinesq approximation is not used, the operating density ρ_0 appears in the body-force term in the momentum equations as $\left(\rho-\rho_0\right)g$. This form of the body-force term follows from the redefinition of pressure in Ansys Fluent as

$$p_s'=p_s-\rho_0 g x \tag{7.68}$$

The hydrostatic pressure in a fluid at rest is then

$$p_s'=0 \tag{7.69}$$

7.3.1.5.1. Setting the Operating Density for a Single Phase Flow

By default, Ansys Fluent will compute the operating density by averaging over all cells. In some cases, you may obtain better results if you explicitly specify the operating density instead of having the solver compute it for you. For example, if you are solving a natural-convection problem with a pressure boundary, it is important to understand that the pressure you are specifying is p_s' in Equation 7.68 (p. 1369). Although you will know the actual pressure p_s, you will need to know the operating density ρ_0 in order to determine p_s' from p_s. Therefore, you should explicitly specify the operating density rather than use the computed average. The specified value should, however, be representative of the average value.

In some cases the specification of an operating density will improve convergence behavior, rather than the actual results. For such cases use the approximate bulk density value as the operating density and be sure that the value you choose is appropriate for the characteristic temperature in the domain.

Note that if you are using the Boussinesq approximation for all fluid materials, the operating density ρ_0 does not appear in the body-force term of the momentum equation. Consequently, you need not specify it.

7.3.1.5.2. Setting the Operating Density for a Multiphase Flow

Details on setting the operation density for multiphase flows can be found in Modeling Buoyancy-Driven Multiphase Flow (p. 2926).

7.3.1.6. Solution Strategies for Buoyancy-Driven Flows

For high-Rayleigh-number flows you may want to consider the solution guidelines below. In addition, the guidelines presented in Solution Strategies for Heat Transfer Modeling (p. 2131) for solving other heat transfer problems can also be applied to buoyancy-driven flows. No steady-state solution exists for some laminar, high-Rayleigh-number flows.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.3.1.6.1. Guidelines for Solving High-Rayleigh-Number Flows

When you are solving a high-Rayleigh-number flow ($Ra > 10^8$), you should follow one of the procedures outlined below for best results.

The first procedure uses a steady-state approach:

1. Start the solution with a lower value of Rayleigh number (for example, 10^7) and run it to convergence using the first-order scheme.
2. To change the effective Rayleigh number, change the value of gravitational acceleration (for example, from 9.8 to 0.098 to reduce the Rayleigh number by two orders of magnitude).
3. Use the resulting data file as an initial guess for the higher Rayleigh number and start the higher-Rayleigh-number solution using the first-order scheme.
4. After you obtain a solution with the first-order scheme you may continue the calculation with a higher-order scheme.

The second procedure uses a time-dependent approach to obtain a steady-state solution [59] (p. 5658):

1. Start the solution from a steady-state solution obtained for the same or a lower Rayleigh number.
2. Estimate the time constant as [15] (p. 5655)

$$\tau = \frac{L}{U} \sim \frac{L^2}{\alpha}\left(PrRa\right)^{-1/2} = \frac{L}{\sqrt{g\beta\Delta TL}} \tag{7.70}$$

   where L and U are the length and velocity scales, respectively. Use a time step size Δt such that

$$\Delta t \approx \frac{\tau}{4} \tag{7.71}$$

   Using a larger time step size may lead to divergence.

3. After oscillations with a typical frequency of $f\tau =$ 0.05–0.09 have decayed, the solution reaches steady-state. Note that τ is the time constant estimated in Equation 7.70 (p. 1370) and f is the oscillation frequency in Hz. In general this solution process may take as many as 5000 time steps to reach steady-state.

7.4. Boundary Conditions

Boundary conditions consist of external, internal, and periodic boundaries. Most of the boundary conditions are discussed in the sections that follow.

7.4.1. Flow Inlet and Exit Boundary Conditions
7.4.2. Using Flow Boundary Conditions
7.4.3. Pressure Inlet Boundary Conditions
7.4.4. Velocity Inlet Boundary Conditions

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.5. Mass-Flow Inlet Boundary Conditions
7.4.6. Mass-Flow Outlet Boundary Conditions
7.4.7. Inlet Vent Boundary Conditions
7.4.8. Intake Fan Boundary Conditions
7.4.9. Pressure Outlet Boundary Conditions
7.4.10. Pressure Far-Field Boundary Conditions
7.4.11. Outflow Boundary Conditions
7.4.12. Outlet Vent Boundary Conditions
7.4.13. Exhaust Fan Boundary Conditions
7.4.14. Degassing Boundary Conditions
7.4.15. Wall Boundary Conditions
7.4.16. Perforated Wall Boundary Conditions
7.4.17. Symmetry Boundary Conditions
7.4.18. Periodic Boundary Conditions
7.4.19. Axis Boundary Conditions
7.4.20. Fan Boundary Conditions
7.4.21. Radiator Boundary Conditions
7.4.22. Porous Jump Boundary Conditions

You can find details about the following types here:

- interface zones: Using Sliding Meshes (p. 1772)
- interior zones: Interior Dialog Box (p. 4966)
- overset zones: Overset Meshes (p. 1183)
- RANS/LES interface zones: Setting Up the Embedded Large Eddy Simulation (ELES) Model (p. 2088)

Note:

By default, boundaries are grouped by type, but you also have the option of grouping them by:

- Alphabetical (List View)
- Name
- Cell Zone (Adjacency)

To change the grouping, right-click the **Boundary Conditions** branch in the Outline View tree and select **Group By**/**List View** or **Name** or **Adjacency**.

Setup → Boundary Conditions **Group By → List View | Name | Adjacency**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can set the default boundary organization method using the **Group boundary conditions by** drop-down in Preferences (**Appearance** branch).

File → **Preferences**

7.4.1. Flow Inlet and Exit Boundary Conditions

Ansys Fluent has a wide range of boundary conditions that permit flow to enter and exit the solution domain. To help you select the most appropriate boundary condition for your application, this section includes descriptions of how each type of condition is used, and what information is needed for each one. Recommendations for determining inlet values of the turbulence parameters are also provided.

7.4.2. Using Flow Boundary Conditions

This section provides an overview of flow boundaries in Ansys Fluent and how to use them.

Ansys Fluent provides 12 types of boundary zone types for the specification of flow inlets and exits: velocity inlet, pressure inlet, mass-flow inlet, mass-flow outlet, pressure outlet, pressure far-field, outflow, inlet vent, intake fan, outlet vent, exhaust fan, and degassing.

The inlet and exit boundary condition options in Ansys Fluent are as follows:

- Velocity inlet boundary conditions are used to define the velocity and scalar properties of the flow at inlet boundaries.
- Pressure inlet boundary conditions are used to define the total pressure and other scalar quantities at flow inlets.
- Mass-flow inlet boundary conditions are used in compressible flows to prescribe a mass flow rate at an inlet. It is not necessary to use mass-flow inlets in incompressible flows because when density is constant, velocity inlet boundary conditions will fix the mass flow. Like pressure and velocity inlets, other inlet scalars are also prescribed.
- Pressure outlet boundary conditions are used to define the static pressure at flow outlets (and also other scalar variables, in case of backflow). The use of a pressure outlet boundary condition instead of an outflow condition often results in a better rate of convergence when backflow occurs during iteration.
- Pressure far-field boundary conditions are used to model a free-stream compressible flow at infinity, with free-stream Mach number and static conditions specified. This boundary type is available only for compressible flows.
- Outflow boundary conditions are used to model flow exits where the details of the flow velocity and pressure are not known prior to solution of the flow problem. They are appropriate where the exit flow is close to a fully developed condition, as the outflow boundary condition assumes a zero streamwise gradient for all flow variables except pressure. They are not appropriate for compressible flow calculations.
- Inlet vent boundary conditions are used to model an inlet vent with a specified loss coefficient, flow direction, and ambient (inlet) total pressure and temperature.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Intake fan boundary conditions are used to model an external intake fan with a specified pressure jump, flow direction, and ambient (intake) total pressure and temperature.
- Outlet vent boundary conditions are used to model an outlet vent with a specified loss coefficient and ambient (discharge) static pressure and temperature.
- Exhaust fan boundary conditions are used to model an external exhaust fan with a specified pressure jump and ambient (discharge) static pressure.
- Degassing boundary conditions are used to model a free surface through which dispersed gas bubbles are allowed to escape, but the continuous liquid phase is not. A typical application is a bubble column in which you want to reduce computational cost by not including the freeboard region in the simulation. The degassing boundary condition is only available for two-phase liquid-gas flows using the Eulerian multiphase model.

7.4.2.1. Determining Turbulence Parameters

When the flow enters the domain at an inlet, outlet, or far-field boundary, Ansys Fluent requires specification of transported turbulence quantities. This section describes which quantities are needed for specific turbulence models and how they must be specified. It also provides guidelines for the most appropriate way of determining the inflow boundary values.

7.4.2.1.1. Specification of Turbulence Quantities Using Profiles

If it is important to accurately represent a boundary layer or fully-developed turbulent flow at the inlet, you should ideally set the turbulence quantities by creating a profile file (see Profiles (p. 1540)) from experimental data or empirical formulas. If you have an analytical description of the profile, rather than data points, you can either use this analytical description to create a profile file, or create a user-defined function to provide the inlet boundary information. (See the Fluent Customization Manual for information on user-defined functions.)

Once you have created the profile function, you can use it as described below:

- Spalart-Allmaras model: Choose **Modified Turbulent Viscosity** or **Turbulent Viscosity Ratio** in the **Turbulence Specification Method** drop-down list and select the appropriate profile name in the drop-down list next to **Turbulent Viscosity** or **Turbulent Viscosity Ratio**. Ansys Fluent computes the boundary value for the modified turbulent viscosity, $\tilde{\nu}$, by combining $\frac{\mu_t}{\mu}$ with the appropriate values of density and molecular viscosity.
- k - ε models: Choose **K and Epsilon** in the **Turbulence Specification Method** drop-down list and select the appropriate profile names in the drop-down lists next to **Turbulent Kinetic Energy** and **Turbulent Dissipation Rate**.
- k - ω models: Choose **K and Omega** in the **Turbulence Specification Method** drop-down list and select the appropriate profile names in the drop-down lists next to **Turbulent Kinetic Energy** and **Specific Dissipation Rate**.
- ε -based Reynolds stress models: Choose **K and Epsilon** in the **Turbulence Specification Method** drop-down list and select the appropriate profile names in the drop-down lists next to **Turbulent Kinetic Energy** and **Turbulent Dissipation Rate**. Choose **Reynolds-Stress Components** in the **Reynolds-Stress Specification Method** drop-down list and select the

7.4.2.1.2. Uniform Specification of Turbulence Quantities

In some situations, it is appropriate to specify a uniform value of the turbulence quantity at the boundary where inflow occurs. Examples are fluid entering a duct, far-field boundaries, or even fully-developed duct flows where accurate profiles of turbulence quantities are unknown.

In most turbulent flows, higher levels of turbulence are generated within shear layers than enter the domain at flow boundaries, making the result of the calculation relatively insensitive to the inflow boundary values. Nevertheless, caution must be used to ensure that boundary values are not so unphysical as to contaminate your solution or impede convergence. This is particularly true of external flows where unphysically large values of effective viscosity in the free stream can "swamp" the boundary layers.

You can use the turbulence specification methods described above to enter uniform constant values instead of profiles. Alternatively, you can specify the turbulence quantities in terms of more convenient quantities such as turbulence intensity, turbulent viscosity ratio, hydraulic diameter, and turbulence length scale. The default Turbulence Specification Method is set to **Turbulent Viscosity Ratio** (for the Spalart-Allmaras model) or **Intensity and Viscosity Ratio** (for the k - ε models, the k - ω models, or the RSM). These quantities are discussed further in the following sections.

7.4.2.1.3. Turbulence Intensity

The turbulence intensity, I, is defined as the ratio of the root-mean-square of the velocity fluctuations, u', to the mean flow velocity, u_{avg}.

A turbulence intensity of 1% or less is generally considered low and turbulence intensities greater than 10% are considered high. Ideally, you will have a good estimate of the turbulence intensity at the inlet boundary from external, measured data. For example, if you are simulating a wind-tunnel experiment, the turbulence intensity in the free stream is usually available from the tunnel characteristics. In modern low-turbulence wind tunnels, the free-stream turbulence intensity may be as low as 0.05%.

For internal flows, the turbulence intensity at the inlets is totally dependent on the upstream history of the flow. If the flow upstream is under-developed and undisturbed, you can use a low turbulence intensity. If the flow is fully developed, the turbulence intensity may be as high as a few percent. The turbulence intensity at the core of a fully-developed duct flow can be derived from an empirical correlation by Blasius for pipe flows (see Chapter 20 Equations (20-4) and (20-5) in [132] (p. 5662)), using the additional estimation of the RMS velocity fluctuation at the pipe core $u'=0.8*u_\tau$:

$$I \equiv \frac{u'}{u_{avg}} = 0.16\left(Re_{D_H}\right)^{-1/8} \tag{7.72}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

At a Reynolds number of 50,000, for example, the turbulence intensity will be 4%, according to this formula.

The default value for turbulence intensity is 5% (medium intensity).

7.4.2.1.4. Turbulence Length Scale and Hydraulic Diameter

The turbulence length scale, ℓ, is a physical quantity related to the size of the large eddies that contain the energy in turbulent flows.

In fully-developed duct flows, ℓ is restricted by the size of the duct, since the turbulent eddies cannot be larger than the duct. An approximate relationship between ℓ and the physical size of the duct is

$$\ell=\frac{0.07L}{C_\mu^{3/4}} \tag{7.73}$$

where L is the relevant dimension of the duct and $1/C_\mu^{3/4}$ ensures consistency with the definition of the turbulent length scales for one- and two-equation turbulence models. The factor of 0.07 is based on the maximum value of the mixing length in fully-developed turbulent pipe flow, where L is the diameter of the pipe. In a channel of non-circular cross-section, you can base L on the hydraulic diameter.

If the turbulence derives its characteristic length from an obstacle in the flow, such as a perforated plate, it is more appropriate to base the turbulence length scale on the characteristic length of the obstacle rather than on the duct size.

It should be noted that the relationship of Equation 7.73 (p. 1375), which relates a physical dimension (L) to the turbulence length scale (ℓ), is not necessarily applicable to all situations. For most cases, however, it is a suitable approximation.

Guidelines for choosing the characteristic length L or the turbulence length scale ℓ for selected flow types are listed below:

- For fully-developed internal flows, choose the **Intensity and Hydraulic Diameter** specification method and specify the hydraulic diameter $L=D_H$ in the **Hydraulic Diameter** field.
- For flows downstream of turning vanes, perforated plates, and so on, choose the **Intensity and Length Scale** method and specify the characteristic length of the flow opening for L in the **Turbulent Length Scale** field.
- For wall-bounded flows in which the inlets involve a turbulent boundary layer, choose the **Intensity and Length Scale** method and use the boundary-layer thickness, δ_{99}, to compute the turbulence length scale, ℓ, from $\ell=0.4\delta_{99}$. Enter this value for ℓ in the **Turbulence Length Scale** field.

7.4.2.1.5. Turbulent Viscosity Ratio

The turbulent viscosity ratio, $\frac{\mu_t}{\mu}$, is directly proportional to the turbulent Reynolds number ($Re_t \equiv k^2/\left(\varepsilon\nu\right)$). Re_t is large (on the order of 100 to 1000) in high-Reynolds-number boundary layers, shear layers, and fully-developed duct flows. However, at the free-stream boundaries of

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

most external flows, $\frac{\mu_t}{\mu}$ is fairly small. Typically, the turbulence parameters are set so that $1<\frac{\mu_t}{\mu}<10$. For internal flows values up to 100 are sensible for the turbulent viscosity ratio, $\frac{\mu_t}{\mu}$. The default value for the turbulent viscosity ratio is set to 10.

To specify quantities in terms of the turbulent viscosity ratio, you can choose **Turbulent Viscosity Ratio** (for the Spalart-Allmaras model) or **Intensity and Viscosity Ratio** (for the k - ε models, the k - ω models, or the RSM). The default value for the turbulence intensity is set to 5% (medium intensity) and the turbulent viscosity ratio, $\frac{\mu_t}{\mu}$, has a default value of 10.

7.4.2.1.6. Relationships for Deriving Turbulence Quantities

To obtain the values of transported turbulence quantities from more convenient quantities such as I, L, or $\frac{\mu_t}{\mu}$, you must typically resort to an empirical relations in addition to the formal definitions of these quantities. Several formal definitions and useful empirical relations, most of which are used within Ansys Fluent, are presented below.

7.4.2.1.7. Estimating Modified Turbulent Viscosity from Turbulence Intensity and Length Scale

To obtain the modified turbulent viscosity, $\tilde{\nu}$, for the Spalart-Allmaras model from the turbulence intensity, I, and length scale, ℓ, the following equation can be used. Note that this equation assumes that there is no viscous damping, that is, $\tilde{\nu}=\nu_t$ (see Modeling the Turbulent Viscosity in the Theory Guide).

$$\tilde{\nu}=C_\mu\sqrt{\frac{3}{2}}\,u_{avg}I\ell \tag{7.74}$$

This formula is also used in Ansys Fluent if you select the **Intensity and Hydraulic Diameter** specification method with the Spalart-Allmaras model. In this case, ℓ is obtained from Equation 7.73 (p. 1375). C_μ ensures consistency with the definition of the eddy viscosity for k - ε and k - ω turbulence models. The value of C_μ is 0.09.

When using a moving reference frame, be aware of the order of the conversion operations applied to the inlet velocity and to the turbulence quantities, which is explained in the next section. It concerns the values of u_{avg} in Equation 7.74 (p. 1376).

7.4.2.1.8. Estimating Turbulent Kinetic Energy from Turbulence Intensity

The relationship between the turbulent kinetic energy, k, and turbulence intensity, I, is

$$k=\frac{3}{2}\left(u_{avg}I\right)^2 \tag{7.75}$$

where u_{avg} is the magnitude of the mean flow velocity.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This relationship is used in Ansys Fluent whenever the **Intensity and Hydraulic Diameter**, **Intensity and Length Scale**, or **Intensity and Viscosity Ratio** method is used instead of specifying explicit values for k and ε or ω.

Important:

The reference frame for the mean flow velocity in Equation 7.75 (p. 1376) corresponds to the Velocity Formulation selected in the General Task Page (p. 4632), see also Choosing the Relative or Absolute Velocity Formulation (p. 1747). When selecting the Reference Frame in any of the inlet boundary condition dialog boxes (see, for example, Figure 7.37: The Velocity Inlet Dialog Box (p. 1390) for the Velocity Inlet Boundary Conditions (p. 1389)), be aware that the specified inlet velocity is first converted to the selected Velocity Formulation and then applied to compute the turbulent kinetic energy from turbulence intensity using Equation 7.75 (p. 1376). If an inlet boundary type does not require the inlet velocity specification (for example, Pressure Inlet Boundary Conditions (p. 1379)), then u_{avg} in Equation 7.75 (p. 1376) is the current local solution velocity magnitude, which corresponds to the selected Velocity Formulation.

7.4.2.1.9. Estimating Turbulent Dissipation Rate from a Length Scale

If you know the turbulence length scale, ℓ, you can determine ε from the relationship

$$\varepsilon = \frac{k^{3/2}}{\ell} \tag{7.76}$$

The determination of ℓ was discussed previously.

This relationship is used in Ansys Fluent whenever the **Intensity and Hydraulic Diameter** or **Intensity and Length Scale** method is used instead of specifying explicit values for k and ε.

7.4.2.1.10. Estimating Turbulent Dissipation Rate from Turbulent Viscosity Ratio

The value of ε can be obtained from the turbulent viscosity ratio $\frac{\mu_t}{\mu}$ and k using the following relationship:

$$\varepsilon = \rho C_\mu \frac{k^2}{\mu} \left(\frac{\mu_t}{\mu} \right)^{-1} \tag{7.77}$$

where C_μ is an empirical constant specified in the turbulence model.

This relationship is used in Ansys Fluent whenever the **Intensity and Viscosity Ratio** method is used instead of specifying explicit values for k and ε.

7.4.2.1.11. Estimating Turbulent Dissipation Rate for Decaying Turbulence

If you are simulating a wind-tunnel situation in which the model is mounted in the test section downstream of a mesh and/or wire mesh screens, you can choose a value of ε such that

$$\varepsilon \approx \frac{\Delta k U_\infty}{L_\infty} \tag{7.78}$$

where Δk is the approximate decay of k you want to have across the flow domain (say, 10% of the inlet value of k), U_∞ is the free-stream velocity, and L_∞ is the streamwise length of the flow

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

domain. Equation 7.78 (p. 1377) is a linear approximation to the power-law decay observed in high-Reynolds-number isotropic turbulence. Its basis is the exact equation for k in decaying turbulence, $U\partial k/\partial x=-\varepsilon$.

If you use this method to estimate ε, you should also check the resulting turbulent viscosity ratio $\frac{\mu_t}{\mu}$ to make sure that it is not too large, using Equation 7.77 (p. 1377).

Although this method is not used internally by Ansys Fluent, you can use it to derive a constant free-stream value of ε that you can then specify directly by choosing **K and Epsilon** in the **Turbulence Specification Method** drop-down list. In this situation, you will typically determine k from I using Equation 7.75 (p. 1376).

7.4.2.1.12. Estimating Specific Dissipation Rate from a Length Scale

If you know the turbulence length scale, ℓ, you can determine ω from the relationship

$$\omega=\frac{k^{1/2}}{C_\mu \ell} \tag{7.79}$$

where C_μ is an empirical constant specified in the turbulence model. The determination of ℓ was discussed previously.

This relationship is used in Ansys Fluent whenever the **Intensity and Hydraulic Diameter** or **Intensity and Length Scale** method is used instead of specifying explicit values for k and ω.

7.4.2.1.13. Estimating Specific Dissipation Rate from Turbulent Viscosity Ratio

The value of ω can be obtained from the turbulent viscosity ratio $\frac{\mu_t}{\mu}$ and k using the following relationship:

$$\omega=\rho\frac{k}{\mu}\left(\frac{\mu_t}{\mu}\right)^{-1} \tag{7.80}$$

This relationship is used in Ansys Fluent whenever the **Intensity and Viscosity Ratio** method is used instead of specifying explicit values for k and ω.

7.4.2.1.14. Estimating Reynolds Stress Components from Turbulent Kinetic Energy

When the RSM is used, if you do not specify the values of the Reynolds stresses explicitly at the inlet using the **Reynolds-Stress Components** option in the **Reynolds-Stress Specification Method** drop-down list, they are approximately determined from the specified values of k. The turbulence is assumed to be isotropic such that

$$\overline{u_i' u_j'}=0 \tag{7.81}$$

and

$$\overline{u_\alpha' u_\alpha'}=\frac{2}{3}k \tag{7.82}$$

(no summation over the index α).

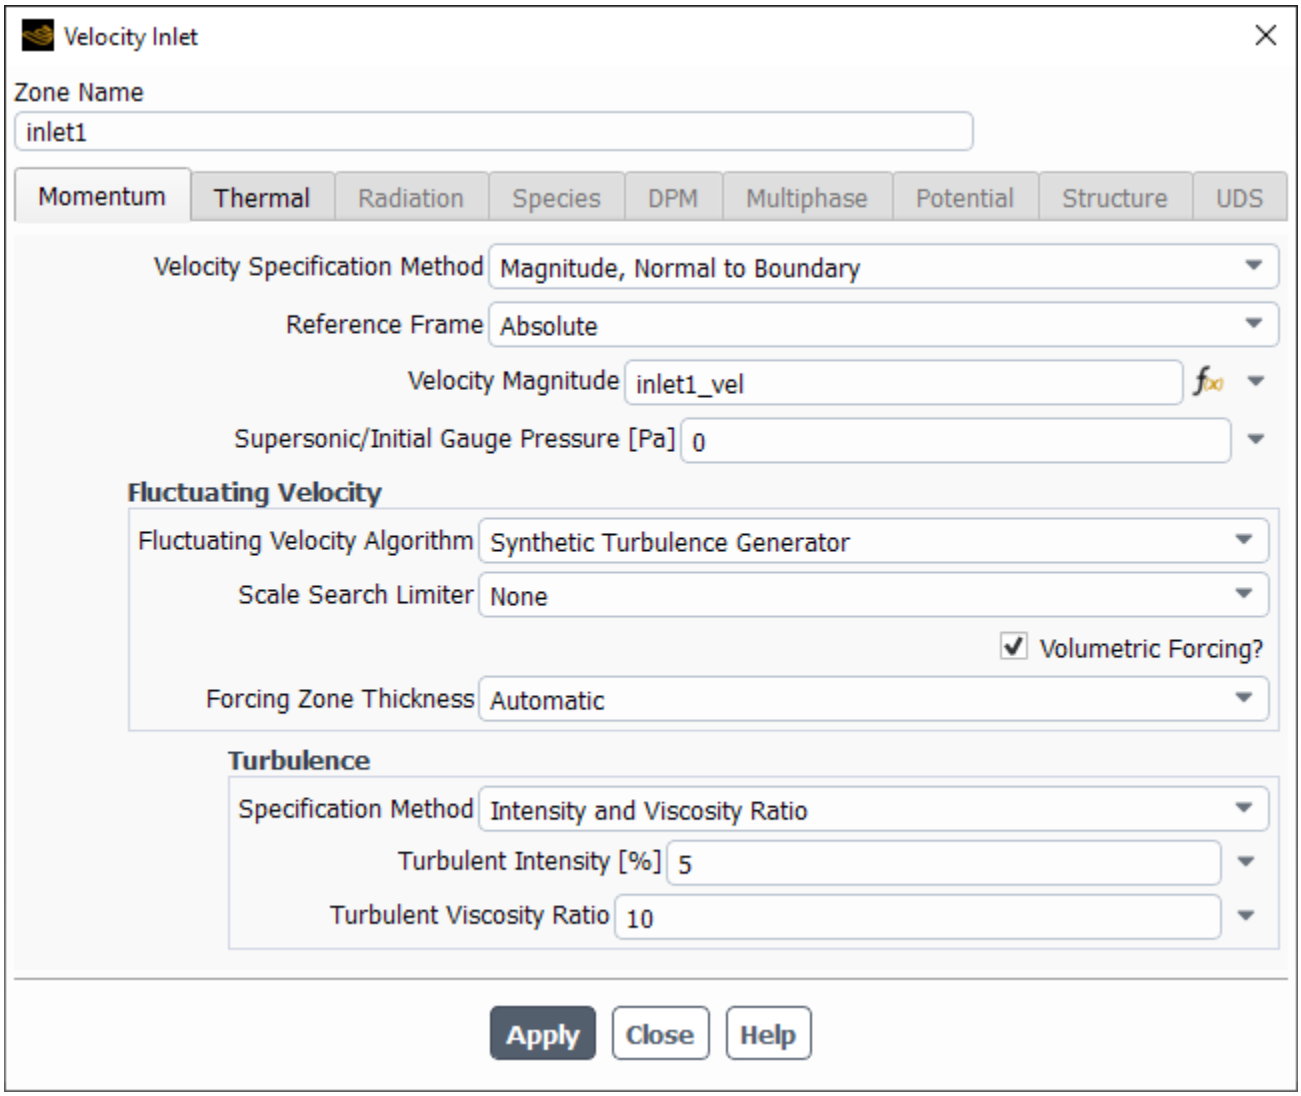
Ansys Fluent will use this method if you select **K or Turbulence Intensity** in the **Reynolds-Stress Specification Method** drop-down list.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.2.1.15. Specifying Inlet Turbulence for Scale Resolving Simulations

When using Scale Resolving Simulations (SAS, DES, SDES, SBES, and LES models), it is possible to specify unsteady **Fluctuating Velocity** at velocity and pressure inlets to generate realistic turbulent content. Therefore, additional input is required for velocity and pressure inlets such as the choice of **Fluctuating Velocity Algorithm** and corresponding parameters (as shown in Figure 7.34: Specifying Inlet Turbulence for Scale Resolving Simulation (p. 1379)). The available methods along with their options are described in Inlet Boundary Conditions for Scale Resolving Simulations in the *Fluent Theory Guide*. Note that even though some LES models do not require specification of the **Turbulence** parameters at the boundary, it is required when a **Fluctuating Velocity Algorithm** is selected. Additional parameters available for the **Fluctuating Velocity Algorithm** are listed in Pressure Inlet Dialog Box (p. 4997) and Velocity Inlet Dialog Box (p. 5018).

Figure 7.34: Specifying Inlet Turbulence for Scale Resolving Simulation



7.4.3. Pressure Inlet Boundary Conditions

Pressure inlet boundary conditions are used to define the fluid pressure at flow inlets, along with all other scalar properties of the flow. They are suitable for both incompressible and compressible flow

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

calculations. Pressure inlet boundary conditions can be used when the inlet pressure is known but the flow rate and/or velocity is not known. This situation may arise in many practical situations, including buoyancy-driven flows. Pressure inlet boundary conditions can also be used to define a "free" boundary in an external or unconfined flow.

For an overview of flow boundaries, see Flow Inlet and Exit Boundary Conditions (p. 1372).

7.4.3.1. Inputs at Pressure Inlet Boundaries

7.4.3.1.1. Summary

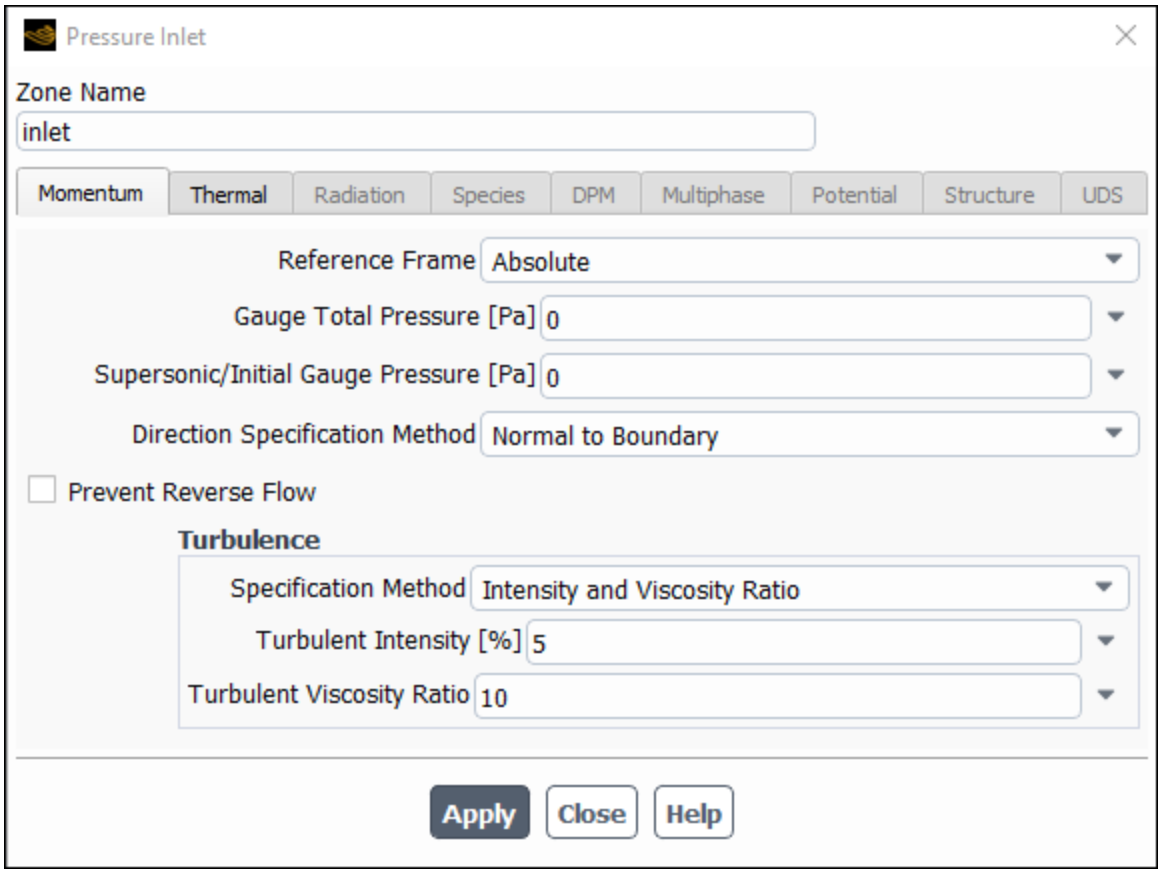
You will enter the following information for a pressure inlet boundary:

- type of reference frame
- total (stagnation) pressure
- total (stagnation) temperature
- flow direction
- static pressure
- turbulence parameters (for turbulent calculations)
- radiation parameters (for calculations using the P-1, DTRM, DO, surface-to-surface, or MC models)
- chemical species mass or mole fractions (for species calculations)
- mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
- progress variable (for premixed or partially premixed combustion calculations)
- discrete phase boundary conditions (for discrete phase calculations)
- multiphase boundary conditions (for general multiphase calculations)
- open channel flow parameters (for open channel flow calculations using the VOF multiphase model)
- acoustic wave model settings

All values are entered in the Pressure Inlet Dialog Box (p. 4997) (Figure 7.35: The Pressure Inlet Dialog Box (p. 1381)), which is opened from the **Boundary Conditions** task page (as described in Setting Cell Zone and Boundary Conditions (p. 1281)). Note that open channel boundary condition inputs are described in Modeling Open Channel Flows (p. 2975), and acoustic wave model settings are described in Boundary Acoustic Wave Models (p. 1503).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.35: The Pressure Inlet Dialog Box



7.4.3.1.1.1. Pressure Inputs and Hydrostatic Head

When gravitational acceleration is activated in the **Operating Conditions** dialog box (accessed from the **Boundary Conditions** task page), the pressure field (including all pressure inputs) will include the hydrostatic head. This is accomplished by redefining the pressure in terms of a modified pressure that includes the hydrostatic head (denoted p') as follows:

$$p' = p - \rho_0 \vec{g} \cdot \vec{r} \tag{7.83}$$

where ρ_0 is a constant operating density, $\vec{g}$ is the gravity vector (also a constant), and

$$\vec{r} = x\hat{i} + y\hat{j} + z\hat{k} \tag{7.84}$$

is the position vector. Noting that

$$\nabla\left(\rho_0 \vec{g} \cdot \vec{r}\right) = \rho_0 \vec{g} \tag{7.85}$$

it follows that

$$\nabla p' = \nabla\left(p - \rho_0 \vec{g} \cdot \vec{r}\right) = \nabla p - \rho_0 \vec{g} \tag{7.86}$$

The substitution of this relation in the momentum equation gives pressure gradient and gravitational body force terms of the form

$$-\nabla p' + \left(\rho - \rho_0\right)\vec{g} \tag{7.87}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where ρ is the fluid density. Therefore, if the fluid density is constant, we can set the operating density ρ_0 equal to the fluid density, thereby eliminating the body force term. If the fluid density is not constant (for example, density is given by the ideal gas law), then the operating density should be chosen to be representative of the average or mean density in the fluid domain, so that the body force term is small.

An important consequence of this treatment of the gravitational body force is that your inputs of pressure (now defined as p') should not include hydrostatic pressure differences. Moreover, reports of static and total pressure will not show any influence of the hydrostatic pressure. See Buoyancy-Driven Flows and Natural Convection (p. 1365) for additional information.

7.4.3.1.1.2. Defining Total Pressure and Temperature

Enter the value for total pressure in the **Gauge Total Pressure** field in the **Pressure Inlet** dialog box. Total temperature is set in the **Thermal** tab, in the **Total Temperature** field.

Remember that the total pressure value is the gauge pressure with respect to the operating pressure defined in the Operating Conditions Dialog Box (p. 4926). Total pressure for an incompressible fluid is defined as

$$p_0 = p_s + \frac{1}{2}\rho|\vec{v}|^2 \tag{7.88}$$

and for a compressible fluid of constant c_p as

$$p_0 = p_s\left(1 + \frac{\gamma-1}{2}M^2\right)^{\gamma/(\gamma-1)} \tag{7.89}$$

where
p_0 = total pressure
p_s = static pressure
M = Mach number
γ = ratio of specific heats $\left(c_p / c_v\right)$

If you are modeling axisymmetric swirl, $\vec{v}$ in Equation 7.88 (p. 1382) will include the swirl component.

The **Total Temperature**, **Gauge Total Pressure**, and flow directions are in absolute or relative to the adjacent cell zone reference frames, based on the **Reference Frame** setting in the **Pressure Inlet** dialog box.

If the cell zone adjacent to a pressure inlet is defined as a moving reference frame zone, and you are using the pressure-based solver, the velocity in Equation 7.88 (p. 1382) (or the Mach number in Equation 7.89 (p. 1382)) will be absolute or relative to the mesh velocity, depending on whether or not the **Absolute** velocity formulation is enabled in the **General** task page. For the density-based solver, the **Absolute** velocity formulation is always used; hence, the velocity in Equation 7.88 (p. 1382) (or the Mach number in Equation 7.89 (p. 1382)) is always the **Absolute** velocity.

For the Eulerian multiphase model, the total temperature, and velocity components must be specified for the individual phases. The **Reference Frame** (**Relative to Adjacent Cell Zone** or

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Absolute) for each of the phases is the same as the reference frame selected for the mixture phase. Note that the total pressure values must be specified in the mixture phase.

Important:

- If the flow is incompressible, then the temperature assigned in the **Pressure Inlet** dialog box will be considered the static temperature.
- For the mixture multiphase model, if a boundary allows a combination of compressible and incompressible phases to enter the domain, then the temperature assigned in the **Pressure Inlet** dialog box will be considered the static temperature at that boundary. If a boundary allows *only a compressible* phase to enter the domain, then the temperature assigned in the **Pressure Inlet** dialog box will be taken as the total temperature (relative/absolute) at that boundary. The total temperature will depend on the **Reference Frame** option selected in the **Pressure Inlet** dialog box.
- For the VOF multiphase model, if a boundary allows a *compressible phase* to enter the domain, then the temperature assigned in the **Pressure Inlet** dialog box will be considered the total temperature at that boundary. The total temperature (relative/absolute) will depend on the **Reference Frame** option chosen in the dialog box. Otherwise, the temperature assigned to the boundary will be considered the static temperature at the boundary.
- For the Eulerian multiphase model, if a boundary allows a mixture of compressible and incompressible phases in the domain, then the temperature of each of the phases will be the total or static temperature, depending on whether the phase is compressible or incompressible.
- Total temperature (relative/absolute) will depend on the **Reference Frame** option chosen in the **Pressure Inlet** dialog box.

7.4.3.1.1.3. Defining the Flow Direction

The flow direction is defined as a unit vector ($\vec{d}$) which is aligned with the local velocity vector, $\vec{v}$. This can be expressed simply as

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\vec{d}=\frac{\vec{v}}{|\vec{v}|} \tag{7.90}$$

Important:

For the inputs in Ansys Fluent, the flow direction $\vec{d}$ need not be a unit vector, as it will be automatically normalized before it is applied.

Important:

For a moving reference frame, the relative flow direction $\vec{d}_r$ is defined in terms of the relative velocity, $\vec{v}_r$. Thus,

$$\vec{d}_r=\frac{\vec{v}_r}{|\vec{v}_r|} \tag{7.91}$$

You can define the flow direction at a pressure inlet explicitly, or you can define the flow to be normal to the boundary. If you choose to specify the direction vector, you can set either the (Cartesian) x, y, and z components, or the (cylindrical) radial, tangential, and axial components.

For moving zone problems calculated using the pressure-based solver, the flow direction will be absolute or relative to the mesh velocity, depending on whether or not the **Absolute** velocity formulation is selected in the **General** task page. For the density-based solver, the flow direction will always be in the absolute frame.

The procedure for defining the flow direction is as follows (refer to Figure 7.35: The Pressure Inlet Dialog Box (p. 1381)):

1. Specify the flow direction by selecting **Direction Vector** or **Normal to Boundary** in the **Direction Specification Method** drop-down list.

2. If you selected **Normal to Boundary** in step 1 and you are modeling axisymmetric swirl, enter the appropriate value for the **Tangential-Component of Flow Direction**. If you chose **Normal to Boundary** and your geometry is 3D or 2D without axisymmetric swirl, there are no additional inputs for flow direction.

3. If you selected **Direction Vector** in step 1, and your geometry is 3D, choose **Cartesian (X, Y, Z)**, **Cylindrical(Radial, Tangential, Axial)**, **Local Cylindrical (Radial, Tangential, Axial)**, or **Local Cylindrical Swirl** from the **Coordinate System** drop-down list. Some notes on these selections are provided below:

   - The **Cartesian** coordinate option is based on the Cartesian coordinate system used by the geometry. Enter appropriate values for the **X**, **Y**, and **Z-Component of Flow Direction**.

   - The **Cylindrical** coordinate system uses the axial, radial, and tangential components based on the following coordinate systems:

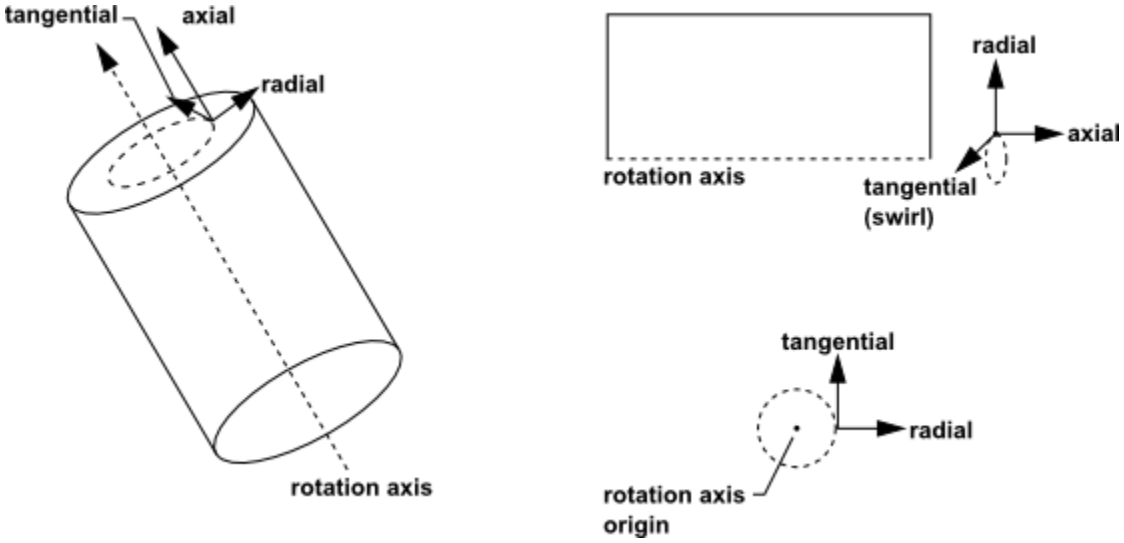
     – For problems involving a single cell zone, the coordinate system is defined by the rotation axis and origin specified in the Fluid Dialog Box (p. 4909).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

– For problems involving multiple zones (for example, multiple reference frames or sliding meshes), the coordinate system is defined by the rotation axis specified in the **Fluid** (or **Solid**) dialog box for the fluid (or solid) zone that is adjacent to the inlet.

For all of the above definitions of the cylindrical coordinate system, positive radial velocities point radially outward from the rotation axis, positive axial velocities are in the direction of the rotation axis vector, and positive tangential velocities are based on the right-hand rule using the positive rotation axis (see Figure 7.36: Cylindrical Velocity Components in 3D, 2D, and Axisymmetric Domains (p. 1385)).

Figure 7.36: Cylindrical Velocity Components in 3D, 2D, and Axisymmetric Domains



- The **Local Cylindrical** coordinate system allows you to define a coordinate system specifically for the inlet. When you use the local cylindrical option, you will define the coordinate system right here in the **Pressure Inlet** dialog box. The local cylindrical coordinate system is useful if you have several inlets with different rotation axes. Enter appropriate values for the **Axial**, **Radial**, and **Tangential-Component of Flow Direction**, and then specify the **X**, **Y**, and **Z** components of the Axis Origin and Axis Direction.

- The **Local Cylindrical Swirl** coordinate system option allows you to define a coordinate system specifically for the inlet where the total pressure, swirl velocity, and the components of the velocity in the axial and radial planes are specified. Enter appropriate values for the **Axial** and **Radial-Component of Flow Direction**, and the **Tangential-Velocity**. Specify the **X**, **Y**, and **Z** components of the Axis Origin and Axis Direction. It is recommended that you start your simulation with a smaller swirl velocity and then progressively increase the velocity to obtain a stable solution.

Important:

Local Cylindrical Swirl should not be used for open channel boundary conditions and on the mixing plane boundaries while using the mixing plane model.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. If you selected **Direction Vector** in step 1, and your geometry is 2D, define the vector components as follows:

   - For a 2D planar geometry, enter appropriate values for the **X**, **Y**, and **Z-Component of Flow Direction**.
   - For a 2D axisymmetric geometry, enter appropriate values for the **Axial**, **Radial-Component of Flow Direction**.
   - For a 2D axisymmetric swirl geometry, enter appropriate values for the **Axial**, **Radial**, and **Tangential-Component of Flow Direction**.

   Figure 7.36: Cylindrical Velocity Components in 3D, 2D, and Axisymmetric Domains (p. 1385) shows the vector components for these different coordinate systems.

7.4.3.1.1.4. Defining Static Pressure

The static pressure (termed the **Supersonic/Initial Gauge Pressure**) must be specified if the inlet flow is supersonic *or* if you plan to initialize the solution based on the pressure inlet boundary conditions. Solution initialization is discussed in Initializing the Solution (p. 3613).

Remember that the static pressure value you enter is relative to the operating pressure set in the Operating Conditions Dialog Box (p. 4926). Note the comments in Pressure Inputs and Hydrostatic Head (p. 1381) regarding hydrostatic pressure.

The **Supersonic/Initial Gauge Pressure** is ignored by Ansys Fluent whenever the flow is sub-sonic, in which case it is calculated from the specified stagnation quantities. If you choose to initialize the solution based on the pressure-inlet conditions, the **Supersonic/Initial Gauge Pressure** will be used in conjunction with the specified stagnation pressure to compute initial values according to the isentropic relations (for compressible flow) or Bernoulli's equation (for incompressible flow). Therefore, for a sub-sonic inlet it should generally be set based on a reasonable estimate of the inlet Mach number (for compressible flow) or inlet velocity (for incompressible flow).

7.4.3.1.1.5. Prevent Reverse Flow

When this option is selected, Fluent will erect artificial walls on the boundary mesh faces to prevent flow out of the domain. The artificial walls are removed when the flow is no longer leaving the domain and when a favorable pressure gradient is recovered at the boundary mesh faces.

When artificial walls are created, Fluent will print a message in the console window indicating the number of faces on which artificial walls have been erected and the equivalent area percentage of the boundary it represents.

Note:

This feature is not available with multiphase flow.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.3.1.1.6. Defining Turbulence Parameters

For turbulent calculations, there are several ways in which you can define the turbulence parameters. Instructions for deciding which method to use and determining appropriate values for these inputs are provided in Determining Turbulence Parameters (p. 1373). Turbulence modeling in general is described in Modeling Turbulence (p. 2025).

7.4.3.1.1.7. Defining Radiation Parameters

The options available depend on which radiation model is active. For details, see Defining Boundary Conditions for Radiation (p. 2181).

7.4.3.1.1.8. Defining Species Mass or Mole Fractions

If you are modeling species transport, you will set the species mass or mole fractions under **Species Mole Fractions** or **Species Mass Fractions**. For details, see Defining Cell Zone and Boundary Conditions for Species (p. 2392).

7.4.3.1.1.9. Defining Non-Premixed Combustion Parameters

If you are using the non-premixed or partially premixed combustion model, you will set the **Mean Mixture Fraction** and **Mixture Fraction Variance** (and the **Secondary Mean Mixture Fraction** and **Secondary Mixture Fraction Variance**, if you are using two mixture fractions), as described in Defining Non-Premixed Boundary Conditions (p. 2524).

7.4.3.1.1.10. Defining Premixed Combustion Boundary Conditions

If you are using the premixed or partially premixed combustion model, you will set the **Progress Variable**, as described in Setting Boundary Conditions for the Progress Variable (p. 2539).

7.4.3.1.1.11. Defining Discrete Phase Boundary Conditions

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the pressure inlet. See Setting Boundary Conditions for the Discrete Phase (p. 2776) for details.

7.4.3.1.1.12. Defining Multiphase Boundary Conditions

If you are using the VOF, mixture, or Eulerian model for multiphase flow, you will need to specify volume fractions for secondary phases and (for some models) additional parameters. See Defining Multiphase Cell Zone and Boundary Conditions (p. 2953) for details.

7.4.3.1.1.13. Defining Open Channel Boundary Conditions

If you are using the VOF model for multiphase flow and modeling open channel flows, you will need to specify the **Free Surface Level**, **Bottom Level**, and additional parameters. See Modeling Open Channel Flows (p. 2975) for details.

7.4.3.2. Default Settings at Pressure Inlet Boundaries

Default settings (in SI) for pressure inlet boundary conditions are as follows:

Gauge Total Pressure	0

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Supersonic/Initial Gauge Pressure	0
Total Temperature	300
Direction Specification Method	Normal to Boundary
Turbulent Intensity	5%
Turbulent Viscosity Ratio	10

7.4.3.3. Calculation Procedure at Pressure Inlet Boundaries

The treatment of pressure inlet boundary conditions by Ansys Fluent can be described as a loss-free transition from stagnation conditions to the inlet conditions. For incompressible flows, this is accomplished by application of the Bernoulli equation at the inlet boundary. In compressible flows, the equivalent isentropic flow relations for an ideal gas are used.

7.4.3.3.1. Incompressible Flow Calculations at Pressure Inlet Boundaries

When flow enters through a pressure inlet boundary, Ansys Fluent uses the boundary condition pressure you input as the total pressure of the fluid at the inlet plane, p_0. In incompressible flow, the inlet total pressure and the static pressure, p_s, are related to the inlet velocity via Bernoulli's equation:

$$p_0 = p_s + \frac{1}{2}\rho v^2 \tag{7.92}$$

With the resulting velocity magnitude and the flow direction vector you assigned at the inlet, the velocity components can be computed. The inlet mass flow rate and fluxes of momentum, energy, and species can then be computed as outlined in Calculation Procedure at Velocity Inlet Boundaries (p. 1394).

For incompressible flows, density at the inlet plane is either constant or calculated as a function of temperature and/or species mass/mole fractions, where the mass or mole fractions are the values you entered as an inlet condition.

If flow exits through a pressure inlet, the total pressure specified is used as the static pressure. For incompressible flows, total temperature is equal to static temperature.

7.4.3.3.2. Compressible Flow Calculations at Pressure Inlet Boundaries

In compressible flows, isentropic relations for an ideal gas are applied to relate total pressure, static pressure, and velocity at a pressure inlet boundary. Your input of total pressure, p_0', at the inlet and the static pressure, p_s', in the adjacent fluid cell are therefore related as

$$\frac{p_0' + p_{op}}{p_s' + p_{op}} = \left(1 + \frac{\gamma - 1}{2} M^2\right)^{\gamma/(\gamma-1)} \tag{7.93}$$

where

$$M \equiv \frac{v}{c} = \frac{v}{\sqrt{\gamma R T_s}} \tag{7.94}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

c = the speed of sound, and $\gamma = c_p / c_v$. Note that the operating pressure, p_{op}, appears in Equation 7.93 (p. 1388) because your boundary condition inputs are in terms of pressure relative to the operating pressure. Given p_0' and p_s', Equation 7.93 (p. 1388) and Equation 7.94 (p. 1388) are used to compute the velocity magnitude of the fluid at the inlet plane. Individual velocity components at the inlet are then derived using the direction vector components.

For compressible flow, the density at the inlet plane is defined by the ideal gas law in the form

$$\rho = \frac{p_s' + p_{op}}{RT_s} \tag{7.95}$$

For multi-species gas mixtures, the specific gas constant, R, is computed from the species mass or mole fractions, Yi that you defined as boundary conditions at the pressure inlet boundary. The static temperature at the inlet, T_s, is computed from your input of total temperature, T_0, as

$$\frac{T_0}{T_s} = 1 + \frac{\gamma - 1}{2} M^2 \tag{7.96}$$

7.4.4. Velocity Inlet Boundary Conditions

Velocity inlet boundary conditions are used to define the flow velocity, along with all relevant scalar properties of the flow, at flow inlets. In this case, the total (or stagnation) pressure is not fixed but will rise (in response to the computed static pressure) to whatever value is necessary to provide the prescribed velocity distribution. This boundary condition is applicable to incompressible and compressible flows.

Important:

Use caution when specifying the velocity inlet boundary condition for a compressible fluid in internal flow modeling. If the flow path is completely choked with no secondary flow path for relief, the velocity inlet boundary condition is not recommended, as it can cause numerical instabilities. In this case, you should switch to the pressure inlet boundary condition or refrain from reaching operating conditions that choke the internal flow. The choking condition can happen in high speed supersonic and transonic flow.

In special instances, a velocity inlet may be used in Ansys Fluent to define the flow velocity at flow exits. (The scalar inputs are not used in such cases.) In such cases you must ensure that overall continuity is maintained in the domain.

For an overview of flow boundaries, see Flow Inlet and Exit Boundary Conditions (p. 1372).

7.4.4.1. Inputs at Velocity Inlet Boundaries

7.4.4.1.1. Summary

You will enter the following information for a velocity inlet boundary:

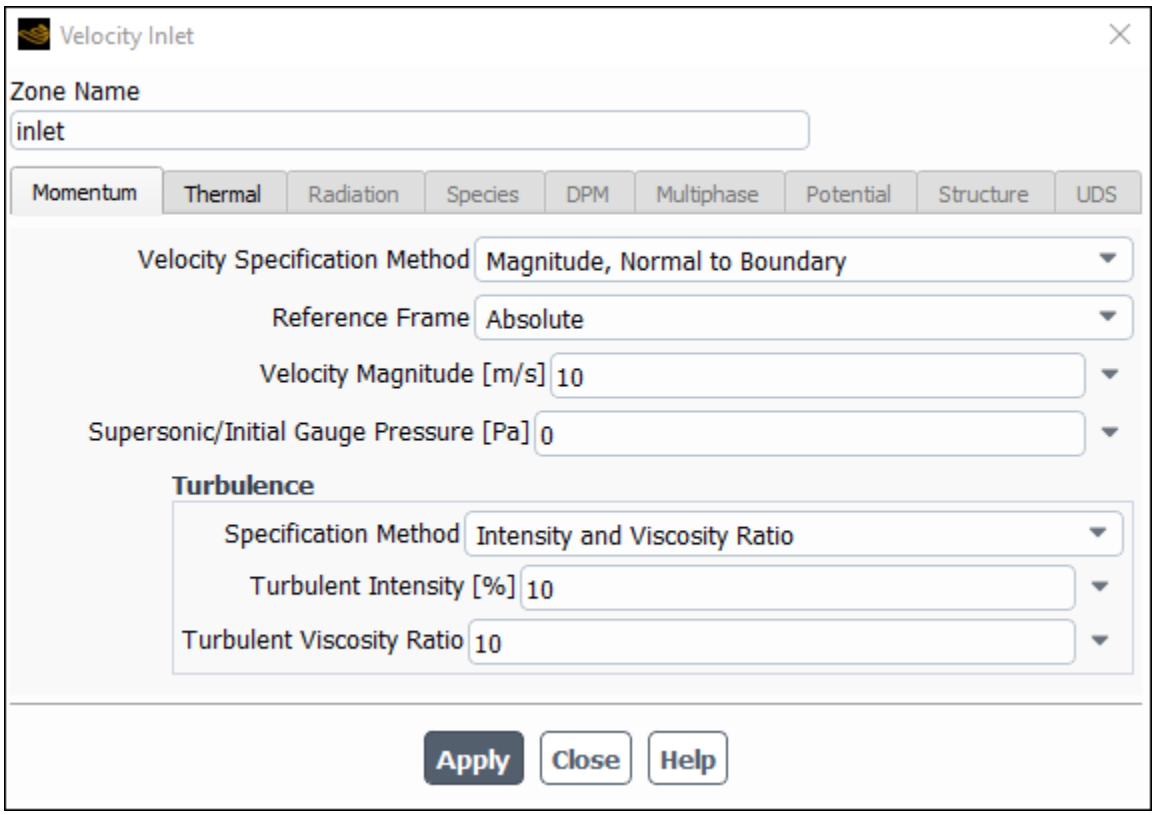
- type of reference frame
- velocity magnitude and direction or velocity components
- swirl velocity (for 2D axisymmetric problems with swirl)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- static pressure
- temperature (for energy calculations)
- outflow gauge pressure (for calculations with the density-based solver)
- turbulence parameters (for turbulent calculations)
- radiation parameters (for calculations using the P-1, DTRM, DO, surface-to-surface, or MC models)
- chemical species mass or mole fractions (for species calculations)
- mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
- progress variable (for premixed or partially premixed combustion calculations)
- discrete phase boundary conditions (for discrete phase calculations)
- multiphase boundary conditions (for general multiphase calculations)
- acoustic wave model settings (see Boundary Acoustic Wave Models (p. 1503))

All values are entered in the Velocity Inlet Dialog Box (p. 5018) (Figure 7.37: The Velocity Inlet Dialog Box (p. 1390)), which is opened from the **Boundary Conditions** task page (as described in Setting Cell Zone and Boundary Conditions (p. 1281)). Note that acoustic wave model settings are described in Boundary Acoustic Wave Models (p. 1503).

Figure 7.37: The Velocity Inlet Dialog Box



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.4.1.2. Defining the Velocity

You can define the inflow velocity by specifying the velocity magnitude and direction, the velocity components, or the velocity magnitude normal to the boundary. If the cell zone adjacent to the velocity inlet is moving (that is, if you are using a moving reference frame, multiple reference frames, or sliding meshes), you can specify either relative or absolute velocities. For axisymmetric problems with swirl in Ansys Fluent, you will also specify the swirl velocity.

The procedure for defining the inflow velocity is as follows:

1. Specify the flow direction by selecting **Magnitude and Direction**, **Components**, or **Magnitude, Normal to Boundary** in the **Velocity Specification Method** drop-down list.

2. If the cell zone adjacent to the velocity inlet is moving, you can choose to specify relative or absolute velocities by selecting **Relative to Adjacent Cell Zone** or **Absolute** in the **Reference Frame** drop-down list. If the adjacent cell zone is not moving, **Absolute** and **Relative to Adjacent Cell Zone** will be equivalent, so you need not visit the list.

3. If you are going to set the velocity magnitude and direction or the velocity components, and your geometry is 3D, choose **Cartesian (X, Y, Z)**, **Cylindrical (Radial, Tangential, Axial)**, or **Local Cylindrical (Radial, Tangential, Axial)** from the **Coordinate System** drop-down list. See Defining the Flow Direction (p. 1383) for information about Cartesian, cylindrical, and local cylindrical coordinate systems.

4. Set the appropriate velocity parameters, as described below for each specification method.

7.4.4.1.3. Setting the Velocity Magnitude and Direction

If you selected **Magnitude and Direction** as the **Velocity Specification Method** in step 1 above, you will enter the magnitude of the velocity vector at the inflow boundary (the **Velocity Magnitude**) and the direction of the vector:

- If your geometry is 2D non-axisymmetric, or you chose in step 3 to use the **Cartesian** coordinate system, you will define the **X**, **Y**, and (in 3D) **Z-Component of Flow Direction**.

- If your geometry is 2D axisymmetric, or you chose in step 3 to use a **Cylindrical** coordinate system, enter the appropriate values of **Radial**, **Axial**, and (if you are modeling axisymmetric swirl or using cylindrical coordinates) **Tangential-Component of Flow Direction**.

- If you chose in step 3 to use a **Local Cylindrical** coordinate system, enter appropriate values for the **Axial**, **Radial**, and **Tangential-Component of Flow Direction**, and then specify the **X**, **Y**, and **Z** components of the **Axis Origin** and the **Axis Direction**.

Figure 7.36: Cylindrical Velocity Components in 3D, 2D, and Axisymmetric Domains (p. 1385) shows the vector components for these different coordinate systems.

7.4.4.1.4. Setting the Velocity Magnitude Normal to the Boundary

If you selected **Magnitude, Normal to Boundary** as the **Velocity Specification Method** in step 1 above, you will enter the magnitude of the velocity vector at the inflow boundary (the **Velocity Magnitude**).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.4.1.5. Setting the Velocity Components

If you selected **Components** as the **Velocity Specification Method** in step 1 above, you will enter the components of the velocity vector at the inflow boundary as follows:

- If your geometry is 2D non-axisymmetric, or you chose in step 3 to use the Cartesian coordinate system, you will define the **X**, **Y**, and (in 3D) **Z-Velocity**.
- If your geometry is 2D axisymmetric without swirl, you will set the **Radial** and **Axial-Velocity**.
- If your model is 2D axisymmetric with swirl, you will set the **Axial**, **Radial**, and **Swirl-Velocity**, and (optionally) the **Angular Velocity**, as described below.
- If you chose in step 3 to use a **Cylindrical** coordinate system, you will set the **Radial**, **Tangential**, and **Axial-Velocity**, and (optionally) the **Angular Velocity**, as described below.
- If you chose in step 3 to use a **Local Cylindrical** coordinate system, you will set the **Radial**, **Tangential**, and **Axial-Velocity**, and (optionally) the **Angular Velocity**, as described below, and then specify the **X**, **Y**, and **Z** component of the **Axis Origin** and the **Axis Direction**.

Important:

Remember that positive values for x, y, and z velocities indicate flow in the positive x, y, and z directions. If flow enters the domain in the negative x direction, for example, you will need to specify a negative value for the x velocity. The same holds true for the radial, tangential, and axial velocities. Positive radial velocities point radially out from the axis, positive axial velocities are in the direction of the axis vector, and positive tangential velocities are based on the right-hand rule using the positive axis.

7.4.4.1.6. Setting the Angular Velocity

If you chose **Components** as the **Velocity Specification Method** in step 1 above, and you are modeling axisymmetric swirl, you can specify the inlet **Angular Velocity** Ω in addition to the **Swirl-Velocity**. Similarly, if you chose **Components** as the **Velocity Specification Method** and you chose in step 3 to use a **Cylindrical** or **Local Cylindrical** coordinate system, you can specify the inlet **Angular Velocity** Ω in addition to the **Tangential-Velocity**.

If you specify Ω, v_θ is computed for each face as Ωr, where r is the radial coordinate in the coordinate system defined by the rotation axis and origin. If you specify both the **Swirl-Velocity** and the **Angular Velocity**, or the **Tangential-Velocity** and the **Angular Velocity**, Ansys Fluent will add v_θ and Ωr to get the swirl or tangential velocity at each face.

7.4.4.1.7. Defining Static Pressure

The static pressure (termed the **Supersonic/Initial Gauge Pressure**) must be specified if the inlet flow is supersonic *or* if you plan to initialize the solution based on the velocity inlet boundary conditions. Solution initialization is discussed in Initializing the Solution (p. 3613).

The **Supersonic/Initial Gauge Pressure** is ignored by Ansys Fluent whenever the flow is subsonic. If you choose to initialize the flow based on the velocity inlet conditions, the **Supersonic/Initial Gauge Pressure** will be used in conjunction with the specified stagnation quantities to compute initial values according to isentropic relations.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Remember that the static pressure value you enter is relative to the operating pressure set in the Operating Conditions Dialog Box (p. 4926). Note the comments in Pressure Inputs and Hydrostatic Head (p. 1381)

7.4.4.1.8. Defining the Temperature

For calculations in which the energy equation is being solved, you will set the static temperature of the flow at the velocity inlet boundary in the **Thermal** tab in the **Temperature** field.

7.4.4.1.9. Defining Outflow Gauge Pressure

If you are using the density-based solver, you can specify an **Outflow Gauge Pressure** for a velocity inlet boundary. If the flow exits the domain at any face on the boundary, that face will be treated as a pressure outlet with the pressure prescribed in the **Outflow Gauge Pressure** field.

7.4.4.1.10. Defining Turbulence Parameters

For turbulent calculations, there are several ways in which you can define the turbulence parameters. Instructions for deciding which method to use and determining appropriate values for these inputs are provided in Determining Turbulence Parameters (p. 1373). Turbulence modeling in general is described in Modeling Turbulence (p. 2025).

7.4.4.1.11. Defining Radiation Parameters

The options available depend on which radiation model is active. For details, see Defining Boundary Conditions for Radiation (p. 2181).

7.4.4.1.12. Defining Species Mass or Mole Fractions

If you are modeling species transport, you will set the species mass or mole fractions under **Species Mole Fractions** or **Species Mass Fractions**. For details, see Defining Cell Zone and Boundary Conditions for Species (p. 2392).

7.4.4.1.13. Defining Non-Premixed Combustion Parameters

If you are using the non-premixed or partially premixed combustion model, you will set the **Mean Mixture Fraction** and **Mixture Fraction Variance** (and the **Secondary Mean Mixture Fraction** and **Secondary Mixture Fraction Variance**, if you are using two mixture fractions), as described in Defining Non-Premixed Boundary Conditions (p. 2524).

7.4.4.1.14. Defining Premixed Combustion Boundary Conditions

If you are using the premixed or partially premixed combustion model, you will set the **Progress Variable**, as described in Setting Boundary Conditions for the Progress Variable (p. 2539).

7.4.4.1.15. Defining Discrete Phase Boundary Conditions

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the velocity inlet. See Setting Boundary Conditions for the Discrete Phase (p. 2776) for details.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.4.1.16. Defining Multiphase Boundary Conditions

If you are using the VOF, mixture, or Eulerian model for multiphase flow, you will need to specify volume fractions for secondary phases and (for some models) additional parameters. See Defining Multiphase Cell Zone and Boundary Conditions (p. 2953) for details.

7.4.4.2. Default Settings at Velocity Inlet Boundaries

Default settings (in SI) for velocity inlet boundary conditions are as follows:

Temperature	300
Velocity Magnitude	0
X-Component of Flow Direction	1
Y-Component of Flow Direction	0
Z-Component of Flow Direction	0
X-Velocity	0
Y-Velocity	0
Z-Velocity	0
Turbulent Intensity	5%
Turbulent Viscosity Ratio	10
Outflow Gauge Pressure	0

7.4.4.3. Calculation Procedure at Velocity Inlet Boundaries

Ansys Fluent uses your boundary condition inputs at velocity inlets to compute the mass flow into the domain through the inlet and to compute the fluxes of momentum, energy, and species through the inlet. This section describes these calculations for the case of flow entering the domain through the velocity inlet boundary and for the less common case of flow exiting the domain through the velocity inlet boundary.

7.4.4.3.1. Treatment of Velocity Inlet Conditions at Flow Inlets

When your velocity inlet boundary condition defines flow entering the physical domain of the model, Ansys Fluent uses both the velocity components and the scalar quantities that you defined as boundary conditions to compute the inlet mass flow rate, momentum fluxes, and fluxes of energy and chemical species.

The mass flow rate entering a fluid cell adjacent to a velocity inlet boundary is computed as

$$\dot{m} = \int \rho \vec{v} \cdot d\vec{A} \tag{7.97}$$

Note that only the velocity component normal to the control volume face contributes to the inlet mass flow rate.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.4.3.2. Treatment of Velocity Inlet Conditions at Flow Exits

Sometimes a velocity inlet boundary is used where flow exits the physical domain. This approach might be used, for example, when the flow rate through one exit of the domain is known or is to be imposed on the model.

Important:

In such cases you must ensure that overall continuity is maintained in the domain.

In the pressure-based solver, when flow exits the domain through a velocity inlet boundary condition, Ansys Fluent uses the boundary velocity to compute the flow flux through the exit flow area and the viscous term in the momentum equation. The convection term in all equations including momentum uses upwind discretization and takes the values of the upstream cells.

In the density-based solver, if the flow exits the domain at any face on the boundary, that face will be treated as a pressure outlet with the pressure prescribed in the **Outflow Gauge Pressure** field.

7.4.4.3.3. Density Calculation

Density at the inlet plane is either constant or calculated as a function of temperature, pressure, and/or species mass/mole fractions, where the mass or mole fractions are the values you entered as an inlet condition.

7.4.5. Mass-Flow Inlet Boundary Conditions

Mass flow boundary conditions can be used in Ansys Fluent to provide a prescribed mass flow rate or mass flux distribution at an inlet. As with a velocity inlet, specifying the mass flux permits the total pressure to vary in response to the interior solution. This is in contrast to the pressure inlet boundary condition (see Pressure Inlet Boundary Conditions (p. 1379)), where the total pressure is fixed while the mass flux varies. The mass-flow inlet is applicable to incompressible and compressible flows.

Important:

Use caution when specifying the mass-flow inlet boundary condition for a compressible fluid in internal flow modeling. If the flow path is completely choked with no secondary flow path for relief, the mass-flow inlet boundary condition is not recommended, as it can cause numerical instabilities. In this case, you should switch to the pressure inlet boundary condition or refrain from reaching operating conditions that choke the internal flow. The choking condition can happen in high speed supersonic and transonic flow.

A mass-flow inlet is often used when it is more important to match a prescribed mass flow rate than to match the total pressure of the inflow stream. An example is the case of a small cooling jet that is bled into the main flow at a fixed mass flow rate, while the velocity of the main flow is governed primarily by a (different) pressure inlet/outlet boundary condition pair. A mass-flow inlet boundary condition can also be used as an outflow by specifying the flow direction away from the solution domain.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.5.1. Limitations and Special Considerations

- The adjustment of inlet total pressure might result in a slower convergence, so if both the pressure inlet boundary condition and the mass-flow inlet boundary condition are acceptable choices, you should choose the former.
- It is not necessary to use mass-flow inlets in incompressible flows because when density is constant, velocity inlet boundary conditions will fix the mass flow.

For an overview of flow boundaries, see Flow Inlet and Exit Boundary Conditions (p. 1372).

7.4.5.2. Inputs at Mass-Flow Inlet Boundaries

7.4.5.2.1. Summary

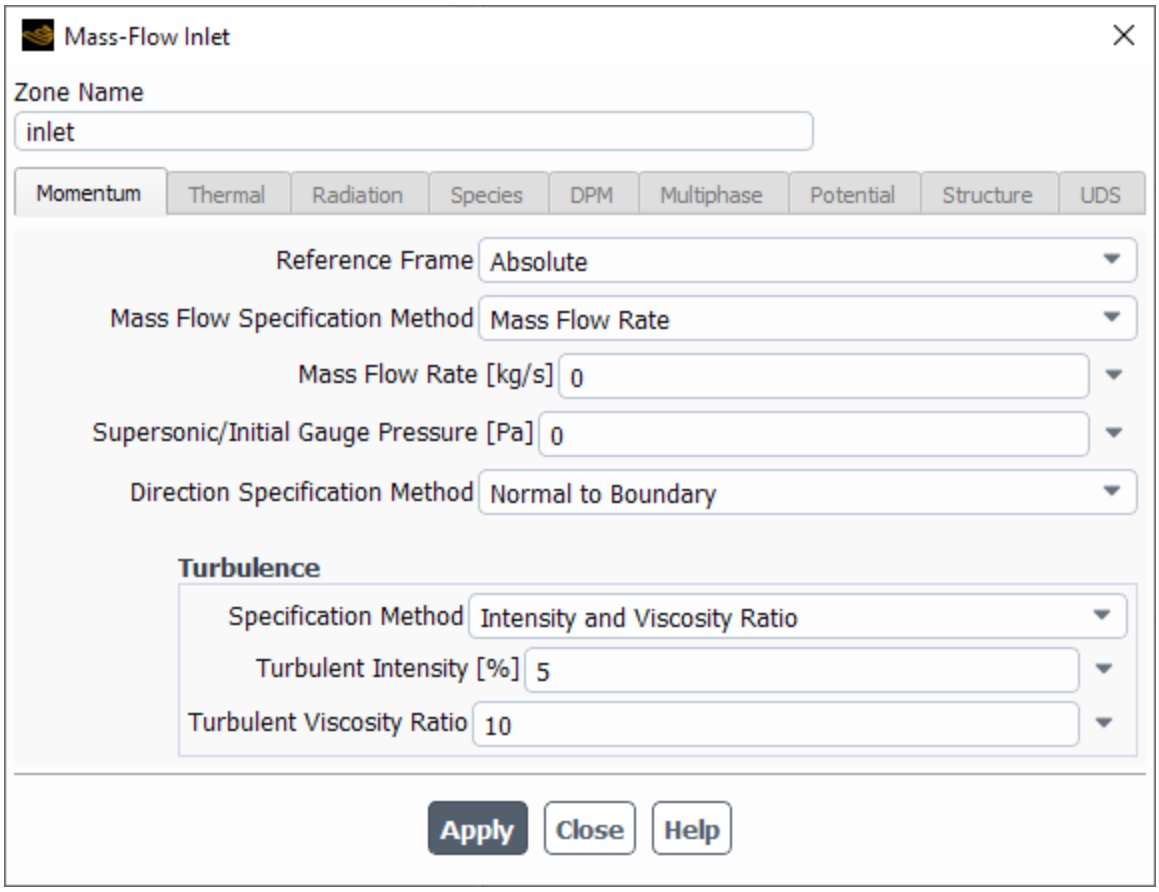
You will enter the following information for a mass-flow inlet boundary:

- type of reference frame
- mass flow rate, mass flux, or (primarily for the mixing plane model) mass flux with average mass flux
- total (stagnation) temperature
- static pressure
- flow direction
- turbulence parameters (for turbulent calculations)
- radiation parameters (for calculations using the P-1, DTRM, DO, surface-to-surface, or MC models)
- chemical species mass or mole fractions (for species calculations)
- mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
- progress variable (for premixed or partially premixed combustion calculations)
- discrete phase boundary conditions (for discrete phase calculations)
- open channel flow parameters (for open channel flow calculations using the VOF multiphase model)
- acoustic wave model settings

All values are entered in the Mass-Flow Inlet Dialog Box (p. 4966) (Figure 7.38: The Mass-Flow Inlet Dialog Box (p. 1397)), which is opened from the **Boundary Conditions** task page (as described in Setting Cell Zone and Boundary Conditions (p. 1281)). Note that open channel boundary condition inputs are described in Modeling Open Channel Flows (p. 2975), and acoustic wave model settings are described in Boundary Acoustic Wave Models (p. 1503).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.38: The Mass-Flow Inlet Dialog Box



7.4.5.2.2. Selecting the Reference Frame

You will have the option to specify the mass flow boundary conditions either in the absolute or relative reference frame, when the cell zone adjacent to the mass-flow inlet is moving. For such a case, choose **Absolute** (the default) or **Relative to Adjacent Cell Zone** in the **Reference Frame** drop-down list. If the cell zone adjacent to the mass-flow inlet is not moving, both formulations are equivalent.

7.4.5.2.3. Defining the Mass Flow Rate or Mass Flux

You can specify the mass flow rate through the inlet zone and have Ansys Fluent convert this value to mass flux, or specify the mass flux directly. For cases where the mass flux varies across the boundary, you can also specify an average mass flux; see below for more information about this specification method.

You can define the mass flux or mass flow rate using a profile or a user-defined function.

The inputs for mass flow rate or flux are as follows:

1. Make a selection in the **Mass Flow Specification Method** drop-down list to specify whether you will define a **Mass Flow Rate**, **Mass Flux**, or **Mass Flux with Average Mass Flux**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. If you selected **Mass Flow Rate** (the default), enter the prescribed **Mass Flow Rate** when **constant** is selected from the drop-down list. Otherwise, select your hooked user-defined function (UDF) or transient profile.

   Important:

   The hooked UDF or transient profile can only be used to provide time-varying specification of mass flow rate. Therefore, the transient solver must be used to run the simulation. Note that the variation of profile with position in space is not applicable with this hookup.

   See `DEFINE_PROFILE` in the Fluent Customization Manual for an example of a mass-flow inlet UDF.

   Important:

   Note that for axisymmetric problems, this mass flow rate is the flow rate through the entire (2π -radian) domain, not through a 1-radian slice.

3. If you selected **Mass Flux**, enter the prescribed **Mass Flux**, or select your hooked UDF or profile.

4. If you selected **Mass Flux with Average Mass Flux**, enter the prescribed **Mass Flux** and **Average Mass Flux**.

   Important:

   Note that for axisymmetric problems, the **Mass Flux** and **Average Mass Flux** is the flux through a 1-radian slice of the domain.

7.4.5.2.4. More About Mass Flux and Average Mass Flux

As noted previously, you can specify an average mass flux with the mass flux. If, for example, you specify a mass flux profile such that the average mass flux integrated over the zone area is 4.7, but you actually want to have a total mass flux of 5, you can keep the profile unchanged, and specify an average mass flux of 5. Ansys Fluent will maintain the profile shape but adjust the values so that the resulting mass flux across the boundary is 5.

The mass flux with average mass flux specification method is also used by the mixing plane model described in Legacy Mixing Plane Model (p. 1934). If the mass-flow inlet boundary is going to represent one of the mixing planes, then you do *not* need to specify the mass flux or flow rate; you can keep the default **Mass Flow Rate** of 1. When you create the mixing plane later on in the problem setup, Ansys Fluent will automatically select the **Mass Flux with Average Mass Flux** method in the **Mass-Flow Inlet** dialog box and set the **Average Mass Flux** to the value obtained by integrating the mass flux profile for the upstream zone. This will ensure that mass is conserved between the upstream zone and the downstream (mass-flow inlet) zone.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.5.2.5. Defining the Total Temperature

Enter the value for the total (stagnation) temperature of the inflow stream in the **Total Temperature** field in the **Thermal** tab.

The total temperature is specified either in the absolute reference frame or relative to the adjacent cell zone, depending on your setting for the **Reference Frame**.

For the Eulerian multiphase model, the total temperature, and mass flux components need to be specified for the individual phases. The **Reference Frame** (**Relative to Adjacent Cell Zone** or **Absolute**) for each of the phases is the same as the reference frame selected for the mixture phase.

Important:

Note that you can only set the reference frame for the mixture, however, the total temperature can only be set for the individual phases.

Important:

- If the flow is incompressible, then the temperature assigned in the **Mass-Flow Inlet** dialog box is considered to be the static temperature.
- For the mixture multiphase model, if a boundary allows a combination of compressible and incompressible phases to enter the domain, then the temperature assigned in the **Mass-Flow Inlet** dialog box is considered to be the static temperature at that boundary. If a boundary allows *only a compressible phase* to enter the domain, then the temperature assigned in the **Mass-Flow Inlet** dialog box is the total temperature (relative/absolute) at that boundary. The total temperature depends on the **Reference Frame** option selected in the **Mass-Flow Inlet** dialog box.
- For the VOF multiphase model, if a boundary allows a *compressible phase* to enter the domain, then the temperature assigned in the **Mass-Flow Inlet** dialog box is considered to be the total temperature at that boundary. The total temperature (relative/absolute) depends on the **Reference Frame** option chosen in the dialog box. Otherwise, the temperature assigned to the boundary is considered to be the static temperature at the boundary.
- For the Eulerian multiphase model, if a boundary allows a mixture of compressible and incompressible phases in the domain, then the temperature of each of the phases is the total or static temperature, depending on whether the phase is compressible or incompressible. Total temperature (relative/absolute) depends on the **Reference Frame** option chosen in the **Mass-Flow Inlet** dialog box.

7.4.5.2.6. Defining Static Pressure

The static pressure (termed the **Supersonic/Initial Gauge Pressure**) must be specified if the inlet flow is supersonic *or* if you plan to initialize the solution based on the pressure inlet boundary conditions. Solution initialization is discussed in Initializing the Solution (p. 3613).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Supersonic/Initial Gauge Pressure** is ignored by Ansys Fluent whenever the flow is subsonic. If you choose to initialize the flow based on the mass-flow inlet conditions, the **Supersonic/Initial Gauge Pressure** will be used in conjunction with the specified stagnation quantities to compute initial values according to isentropic relations.

Remember that the static pressure value you enter is relative to the operating pressure set in the Operating Conditions Dialog Box (p. 4926). Note the comments in Pressure Inputs and Hydrostatic Head (p. 1381) regarding hydrostatic pressure.

7.4.5.2.7. Defining the Flow Direction

You can define the flow direction at a mass-flow inlet explicitly, or you can define the flow to be normal to the boundary.

The procedure for defining the flow direction is as follows, referring to Figure 7.38: The Mass-Flow Inlet Dialog Box (p. 1397):

1. Specify the flow direction by selecting **Direction Vector** or **Normal to Boundary** in the **Direction Specification Method** drop-down list. The default value for this option is **Normal to Boundary**.

2. If you selected **Direction Vector** and your geometry is 2D, go to the next step. If your geometry is 3D, choose **Cartesian (X, Y, Z)**, **Cylindrical (Radial, Tangential, Axial)**, **Local Cylindrical (Radial, Tangential, Axial)**, or **Local Cylindrical Swirl** in the **Coordinate System** drop-down list. See Defining the Flow Direction (p. 1383) for information about Cartesian, cylindrical, local cylindrical, and local cylindrical swirl coordinate systems.

3. If you selected **Direction Vector**, set the vector components as follows:

   - If your geometry is 2D non-axisymmetric, or you chose to use a 3D **Cartesian** coordinate system, enter appropriate values for the **X-**, **Y-**, and (in 3D) **Z-Component of Flow Direction**.

   - If your geometry is 2D axisymmetric, or you chose to use a 3D **Cylindrical** coordinate system, enter appropriate values for the **Axial-**, **Radial-**, and (if you are modeling swirl or using cylindrical coordinates) **Tangential-Component of Flow Direction**.

   - If you chose to use a 3D **Local Cylindrical** coordinate system, enter appropriate values for the **Axial-**, **Radial-**, and **Tangential-Component of Flow Direction**, and then specify the **X**, **Y**, and **Z** components of **Axis Origin** and the **Axis Direction**.

   - If you chose to use a 3D **Local Cylindrical Swirl** coordinate system, enter appropriate values for the **Axial-** and **Radial-Component of Flow Direction** in the axial and radial planes, and the **Tangential-Velocity**. Specify the **X**, **Y**, and **Z** components of the **Axis Origin** and the **Axis Direction**.

     Important:

     Local Cylindrical Swirl should not be used for open channel boundary conditions and on the mixing plane boundaries, while using the mixing plane model.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. If you selected **Normal to Boundary**, there are no additional inputs for flow direction.

> **Important:**
>
> Note that if you are modeling axisymmetric swirl, the flow direction will be normal to the boundary; that is, there will be no swirl component at the boundary for axisymmetric swirl.

7.4.5.2.8. Defining Turbulence Parameters

For turbulent calculations, there are several ways in which you can define the turbulence parameters. Instructions for deciding which method to use and determining appropriate values for these inputs are provided in Determining Turbulence Parameters (p. 1373). Turbulence modeling is described in Modeling Turbulence (p. 2025).

7.4.5.2.9. Defining Radiation Parameters

The options available depend on which radiation model is active. For details, see Defining Boundary Conditions for Radiation (p. 2181).

7.4.5.2.10. Defining Species Mass or Mole Fractions

If you are modeling species transport, you will set the species mass or mole fractions under **Species Mole Fractions** or **Species Mass Fractions**. For details, see Defining Cell Zone and Boundary Conditions for Species (p. 2392).

7.4.5.2.11. Defining Non-Premixed Combustion Parameters

If you are using the non-premixed or partially premixed combustion model, you will set the **Mean Mixture Fraction** and **Mixture Fraction Variance** (and the **Secondary Mean Mixture Fraction** and **Secondary Mixture Fraction Variance**, if you are using two mixture fractions), as described in Defining Non-Premixed Boundary Conditions (p. 2524).

7.4.5.2.12. Defining Premixed Combustion Boundary Conditions

If you are using the premixed or partially premixed combustion model, you will set the **Progress Variable**, as described in Setting Boundary Conditions for the Progress Variable (p. 2539).

7.4.5.2.13. Defining Discrete Phase Boundary Conditions

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the mass-flow inlet. See Setting Boundary Conditions for the Discrete Phase (p. 2776) for details.

7.4.5.2.14. Defining Open Channel Boundary Conditions

If you are using the VOF model for multiphase flow and modeling open channel flows, you will need to specify the **Free Surface Level**, **Bottom Level**, and additional parameters. See Modeling Open Channel Flows (p. 2975) for details.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.5.3. Default Settings at Mass-Flow Inlet Boundaries

Default settings (in SI) for mass-flow inlet boundary conditions are as follows:

Mass Flow Rate	1
Total Temperature	300
Supersonic/Initial Gauge Pressure	0
X-Component of Flow Direction	1
Y-Component of Flow Direction	0
Z-Component of Flow Direction	0
Turbulent Intensity	5%
Turbulent Viscosity Ratio	10

7.4.5.4. Calculation Procedure at Mass-Flow Inlet Boundaries

When mass flow boundary conditions are used for an inlet zone, a velocity is computed for each face in that zone, and this velocity is used to compute the fluxes of all relevant solution variables into the domain. With each iteration, the computed velocity is adjusted so that the correct mass flow value is maintained.

To compute this velocity, your inputs for mass flow rate, flow direction, static pressure, and total temperature are used.

There are two ways to specify the mass flow rate. The first is to specify the total mass flow rate, $\dot{m}$, for the inlet. The second is to specify the mass flux, ρv_n (mass flow rate per unit area). If a total mass flow rate is specified, Ansys Fluent converts it internally to a uniform mass flux by dividing the mass flow rate by the total inlet area:

$$\rho v_n = \frac{\dot{m}}{A} \tag{7.98}$$

If the direct mass flux specification option is used, the mass flux can be varied over the boundary by using profile files or user-defined functions. If the average mass flux is also specified (either explicitly by you or automatically by Ansys Fluent), it is used to correct the specified mass flux profile, as described earlier in this section.

Once the value of ρv_n at a given face has been determined, the density, ρ, at the face must be determined in order to find the normal velocity, v_n. The manner in which the density is obtained depends upon whether the fluid is modeled as an ideal gas or not. Each of these cases is examined below.

7.4.5.4.1. Flow Calculations at Mass Flow Boundaries for Ideal Gases

If the fluid is an ideal gas, the static temperature and static pressure are required to compute the density:

$$p = \rho R T \tag{7.99}$$

If the inlet is supersonic, the static pressure used is the value that has been set as a boundary condition. If the inlet is subsonic, the static pressure is extrapolated from the cells inside the inlet face.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The static temperature at the inlet is computed from the total enthalpy, which is determined from the total temperature that has been set as a boundary condition. The total enthalpy is given by

$$h_0(T_0) = h(T) + \frac{1}{2}v^2 \tag{7.100}$$

where the velocity magnitude is related to the mass flow rate given by Equation 7.98 (p. 1402) and the known user-specified flow direction vector. Using Equation 7.99 (p. 1402) to relate density to the (known) static pressure and (unknown) temperature, Equation 7.100 (p. 1403) can be solved to obtain the static temperature.

7.4.5.4.2. Flow Calculations at Mass Flow Boundaries for Incompressible Flows

When you are modeling incompressible flows, the static temperature is equal to the total temperature. The density at the inlet is either constant or readily computed as a function of the temperature and (optionally) the species mass or mole fractions. The velocity is then computed using Equation 7.98 (p. 1402).

7.4.5.4.3. Flux Calculations at Mass Flow Boundaries

To compute the fluxes of all variables at the inlet, the flux velocity, v_n, is used along with the inlet value of the variable in question. For example, the flux of mass is ρv_n, and the flux of turbulence kinetic energy is $\rho k v_n$. These fluxes are used as boundary conditions for the corresponding conservation equations during the course of the solution.

7.4.6. Mass-Flow Outlet Boundary Conditions

Mass-flow outlet boundaries can be used in Ansys Fluent to pump flow out of the domain at a prescribed mass flow rate or mass flux distribution. A mass-flow outlet is often used when it is more important to match a prescribed mass flow rate than to match the static pressure of the outflow stream.

7.4.6.1. Limitations

Mass-flow outlet boundaries is not supported with the Wet Steam model in the density-based solver.

7.4.6.2. Inputs at Mass-Flow Outlet Boundaries

7.4.6.2.1. Summary

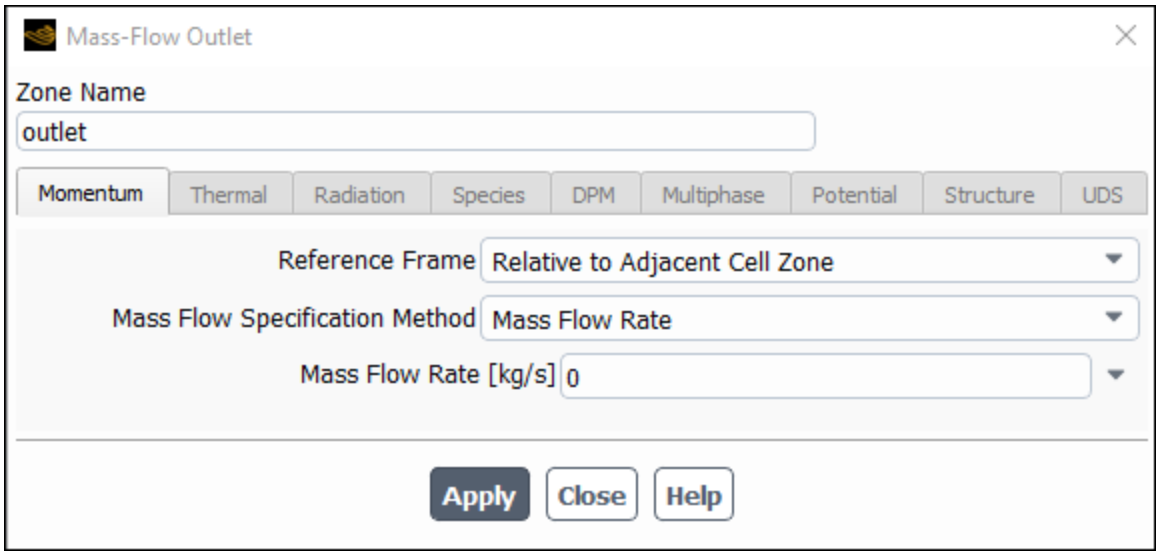
You will enter the following information for a mass-flow outlet boundary:

- mass flow rate, mass flux, mass flux with average mass flux, or exit corrected mass flow rate with reference temperature and gauge pressure
- radiation parameters (for calculations using the P-1, DTRM, DO, surface-to-surface, or MC models)
- discrete phase boundary conditions (for discrete phase calculations)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

All values are entered in the Mass-Flow Outlet Dialog Box (p. 4974) (Figure 7.39: The Mass-Flow Outlet Dialog Box (p. 1404)), which is opened from the **Boundary Conditions** task page (as described in Setting Cell Zone and Boundary Conditions (p. 1281)).

Figure 7.39: The Mass-Flow Outlet Dialog Box



7.4.6.2.2. Selecting the Reference Frame

Mass-flow outlets only support the **Relative to Adjacent Cell Zone** specification for the **Reference Frame**.

7.4.6.2.3. Defining the Mass Flow Rate or Mass Flux

You can specify the mass flow rate through the outlet zone and have Ansys Fluent convert this value to mass flux, or specify the mass flux directly. For cases where the mass flux varies across the boundary, you can specify an average mass flux. For compressible problems, you can specify that the mass flow rate is adjusted to total conditions at the outlet, thus maintaining a constant exit corrected mass flow rate.

You can define the mass flow or mass flux rate using a profile or a user-defined function (UDF). For an example of a mass-flow outlet UDF, see `DEFINE_PROFILE` in the Fluent Customization Manual.

Important:

The hooked UDF or transient profile can only be used to provide time-varying specification of mass flow or mass flux rate. Therefore, the transient solver must be used to run the simulation. Note that the variation of profile with position in space is not applicable with this hookup.

The inputs for mass flow rate or flux are as follows:

1. Make a selection in the **Mass Flow Specification Method** drop-down list to specify whether you will define a **Mass Flow Rate**, **Mass Flux**, **Mass Flux with Average Mass Flux**, or (if the

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

density of the material is defined either as an ideal gas or using a real gas model) **Exit Corrected Mass Flow Rate**.

2. If you selected **Mass Flow Rate** (the default), enter the prescribed **Mass Flow Rate** when **constant** is selected from the drop-down list. Otherwise, select your hooked user-defined function (UDF) or transient profile.

3. If you selected **Mass Flux**, enter the prescribed **Mass Flux** (or select your hooked UDF or profile).

4. If you selected **Mass Flux with Average Mass Flux**, enter the prescribed **Mass Flux** (or select your hooked UDF or profile) and **Average Mass Flux**.

   Note that if you specify a mass flux profile such that the average mass flux integrated over the zone area is 4.7, but you actually want to have a total mass flux of 5, you can keep the profile unchanged, and specify an average mass flux of 5. Ansys Fluent will maintain the profile shape but adjust the values so that the resulting mass flux across the boundary is 5.

5. If you selected **Exit Corrected Mass Flow Rate**, enter the prescribed **Exit Corrected Mass Flow Rate** (or select your hooked UDF or profile); this corresponds to $\dot{m}_{\text{cor}}$ in Equation 7.102 (p. 1407). Then enter the **ECMF Reference Temperature** (T_{ref}) and the **ECMF Reference Gauge Pressure** (P_{ref}). For complete details about this method, see Exit Corrected Mass Flow Rate (p. 1407).

Important:

Note that for axisymmetric problems:

- If you provide a mass flow rate, you must specify the flow rate through the entire (2π -radian) domain, not through a 1-radian slice.
- If you provide a mass flux rate, you must specify the flux through a 1-radian slice of the domain.

The mass flow boundary will be pumping flow out of the domain normal to the boundary at the prescribed rate or flux. If the mass flow rate is specified, then by default, the fluxes on the boundary will be allowed to vary to preserve the flow profile out of the domain. At convergence, the total mass flow rate should match the specified value.

Important:

Note that if constant mass flux is needed rather than the default variable fluxes to preserve the profiles, then you can do so via the text command `define/boundary-`

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

`conditions/bc-settings/mass-flow`. Answer `no` when asked to `preserve profile while flow leaves`.

Note:

The mass-flow outlet boundary condition is designed to be strictly used only when flow is leaving the domain; it should not be used for mixed flow conditions (where flow is flowing in and out) or when flow is changing directions.

7.4.6.2.4. Defining Radiation Parameters

The options available depend on which radiation model is active. For details, see Defining Boundary Conditions for Radiation (p. 2181).

7.4.6.2.5. Defining Discrete Phase Boundary Conditions

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the mass-flow outlet. See Setting Boundary Conditions for the Discrete Phase (p. 2776) for details.

7.4.6.3. Default Settings at Mass-Flow Outlet Boundaries

Default settings (in SI) for mass-flow outlet boundary conditions are as follows:

Mass Flow Rate	1

7.4.6.4. Calculation Procedure at Mass-Flow Outlet Boundaries

For the **Mass Flow Rate** specification method, you specify the total mass flow rate, $\dot{m}$, for the outlet. For the **Mass Flux** or **Mass Flux with Averaged Mass Flux** specification methods, you specify the mass flux, ρv_n (mass flow rate per unit area). If a total mass flow rate is specified, Ansys Fluent converts it internally to a uniform mass flux by dividing the mass flow rate by the total outlet area:

$$\rho v_n = \frac{\dot{m}}{A} \tag{7.101}$$

If the direct mass flux specification option is used, the mass flux can be varied over the boundary by using profile files or user-defined functions. If the average mass flux is also specified, it is used to correct the specified mass flux profile, as described previously in this section.

Once the value of ρv_n at a given face has been determined, the density, ρ, at the face must be determined in order to find the normal velocity, v_n.

Boundary velocities are scaled to achieve the specified value of mass flow rate or mass flux. When the mass-flow outlet is used with the profile preserving feature, a scaling factor of the specified mass flow rate over the computed mass flow rate at the boundary is used to scale the normal face velocities at the boundary. The other velocity components will be extrapolated from the interior. Flow variables such as pressure, temperature, species, or other scalar quantities will be also extrapolated from adjacent cell centers.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.6.4.1. Exit Corrected Mass Flow Rate

The **Exit Corrected Mass Flow Rate** specification method adjusts the mass flow rate to the total conditions at the outlet, maintaining a constant exit corrected mass flow rate. This boundary option is mainly intended for turbomachinery applications. This method allows you to sweep through the complete machine operational range, including machine operating points from choked flow to stall conditions. When using the **Exit Corrected Mass Flow Rate** specification method, the boundary operates like a mass-flow outlet on the left side of the speedline curve away from the best efficiency point, and more like a pressure outlet boundary to the right of the best efficiency point all the way beyond the choke point. This method allows you to specify the equivalent mass flow, based on similar criteria, corrected to a specified reference temperature and pressure.

For compressible flows, the exit corrected mass flow rate ($\dot{m}_{\text{cor}}$) is calculated as:

$$\dot{m}_{\text{cor}} = \dot{m} \frac{\sqrt{\tilde{T}_0 / T_{\text{ref}}}}{\tilde{P}_0 / P_{\text{ref}}} \tag{7.102}$$

where $\tilde{P}_0$ and $\tilde{T}_0$ are mass-averaged values of total pressure and temperature in the absolute frame at the outlet. P_{ref} and T_{ref} are the reference conditions, which are constants in the equation. It should be noted that the numerical behavior of the boundary condition is not affected by the choice of reference conditions; rather, the reference conditions simply provide a dimensional meaning to the otherwise non-dimensional mass flow rate. It is typical to specify these reference conditions to be the same as the inflow total pressure and temperature.

In order to maintain a constant exit corrected mass flow, you can observe that the resulting mass flow rate must be proportional to the exit total pressure and inversely proportional to the square root of the exit total temperature (or equivalently, inversely proportional to the stagnation speed of sound). This allows the boundary condition to adapt dynamically to varying operating conditions, while remaining stable as the flow develops from the initial guess.

Note that the **Exit Corrected Mass Flow Rate** specification method is only available for ideal gas and real gas materials.

You can obtain an initial exit corrected mass flow rate value ($\dot{m}_{\text{cor}}$) from a previously converged case that uses standard inlet and outlet boundaries (for example, a pressure inlet and a pressure outlet). Use the converged solution to obtain the mass-flow-averaged value of $\tilde{T}_0$ and $\tilde{P}_0$ at the outlet boundary, as well as the mass flow rate ($\dot{m}$). These values can then be applied to Equation 7.102 (p. 1407) along with P_{ref} and T_{ref} (which are usually taken as the inflow total temperature and pressure). After you have calculated the exit corrected mass flow rate, you can adjust this value up or down in order to traverse the speed line from choke to stall.

7.4.7. Inlet Vent Boundary Conditions

Inlet vent boundary conditions are used to model an inlet vent with a specified loss coefficient, flow direction, and ambient (inlet) pressure and temperature.

7.4.7.1. Inputs at Inlet Vent Boundaries

You will enter the following information for an inlet vent boundary:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

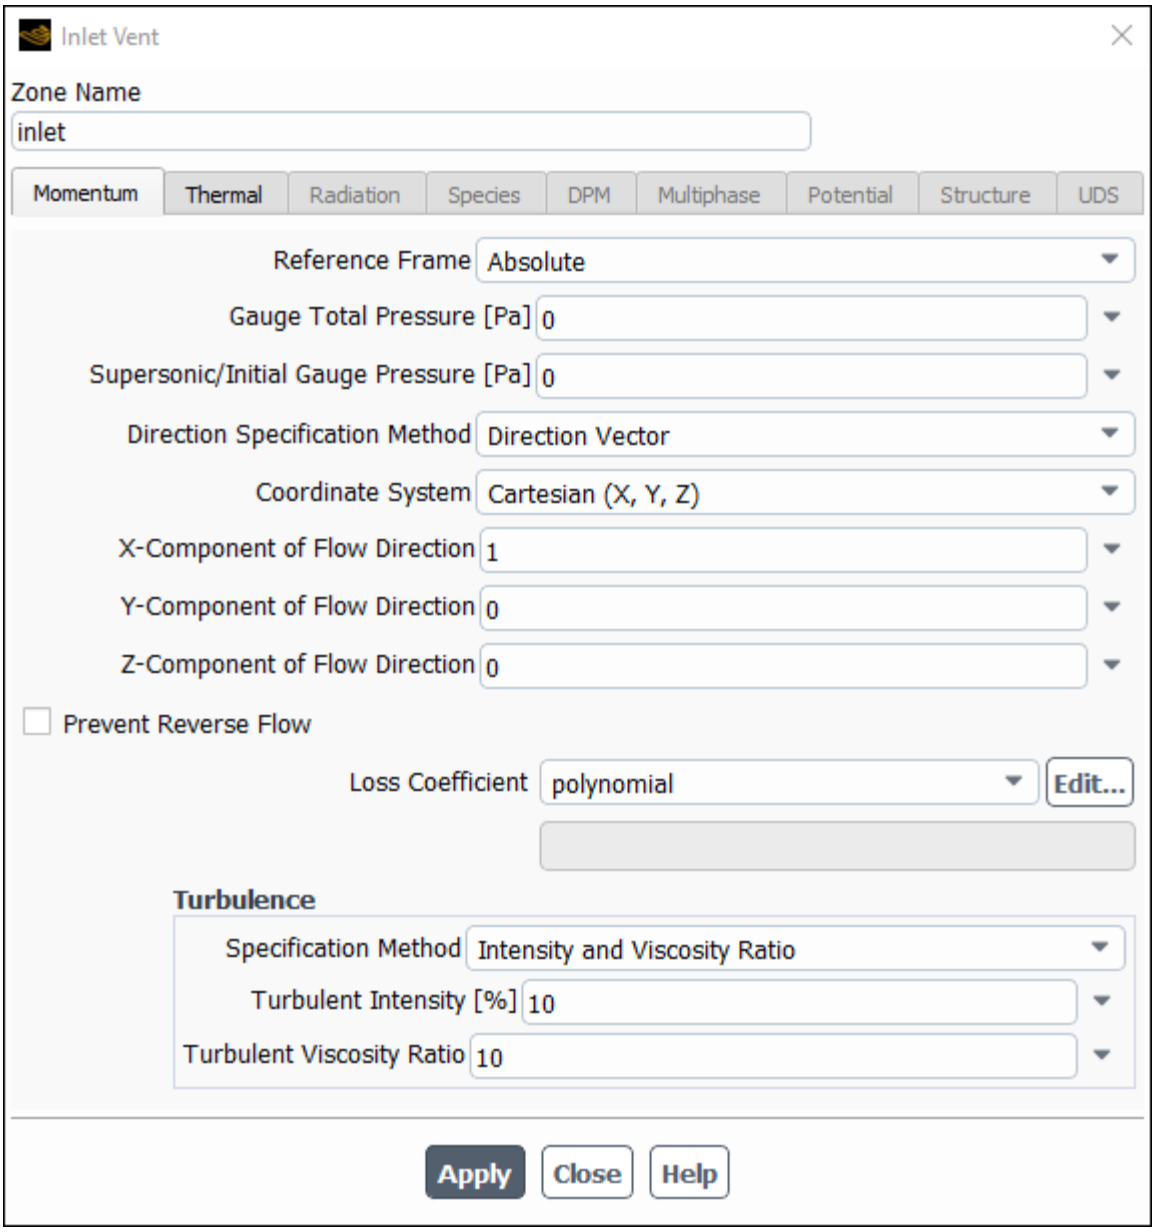
- type of reference frame
- total (stagnation) pressure
- total (stagnation) temperature
- flow direction
- static pressure
- turbulence parameters (for turbulent calculations)
- radiation parameters (for calculations using the P-1, DTRM, DO, surface-to-surface, or MC models)
- chemical species mass or mole fractions (for species calculations)
- mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
- progress variable (for premixed or partially premixed combustion calculations)
- discrete phase boundary conditions (for discrete phase calculations)
- multiphase boundary conditions (for general multiphase calculations)
- loss coefficient
- open channel flow parameters (for open channel flow calculations using the VOF multiphase model)

All values are entered in the Inlet Vent Dialog Box (p. 4951) (Figure 7.40: The Inlet Vent Dialog Box (p. 1409)), which is opened from the **Boundary Conditions** task page (as described in Setting Cell Zone and Boundary Conditions (p. 1281)).

The first 12 items listed above are specified in the same way that they are specified at pressure inlet boundaries. See Inputs at Pressure Inlet Boundaries (p. 1380) for details. Specification of the loss coefficient is described here. Open channel boundary condition inputs are described in Modeling Open Channel Flows (p. 2975).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.40: The Inlet Vent Dialog Box



7.4.7.1.1. Specifying the Loss Coefficient

An inlet vent is considered to be infinitely thin, and the pressure drop through the vent is assumed to be proportional to the dynamic head of the fluid, with an empirically determined loss coefficient that you supply. That is, the pressure drop, Δp, varies with the normal component of velocity through the vent, v, as follows:

$$\Delta p = k_L \frac{1}{2} \rho v^2 \tag{7.103}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where ρ is the fluid density, and k_L is the non-dimensional loss coefficient.

Important:

Δp is the pressure drop in the direction of the flow; therefore the vent will appear as a resistance even in the case of backflow.

You can define the **Loss-Coefficient** across the vent as a **constant**, **polynomial**, **piecewise-linear**, or **piecewise-polynomial** function of the normal velocity. The dialog boxes for defining these functions are the same as those used for defining temperature-dependent properties. See Defining Properties Using Temperature-Dependent Functions (p. 1590) for details.

7.4.8. Intake Fan Boundary Conditions

Intake fan boundary conditions are used to model an external intake fan with a specified pressure jump, flow direction, and ambient (intake) pressure and temperature.

Note:

The intake fan boundary condition considers only momentum. Diffusion processes are not considered.

7.4.8.1. Inputs at Intake Fan Boundaries

You will enter the following information for an intake fan boundary:

- type of reference frame
- total (stagnation) pressure
- total (stagnation) temperature
- flow direction
- static pressure
- turbulence parameters (for turbulent calculations)
- radiation parameters (for calculations using the P-1, DTRM, DO, surface-to-surface, or MC models)
- chemical species mass or mole fractions (for species calculations)
- mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
- progress variable (for premixed or partially premixed combustion calculations)
- discrete phase boundary conditions (for discrete phase calculations)
- multiphase boundary conditions (for general multiphase calculations)
- pressure jump

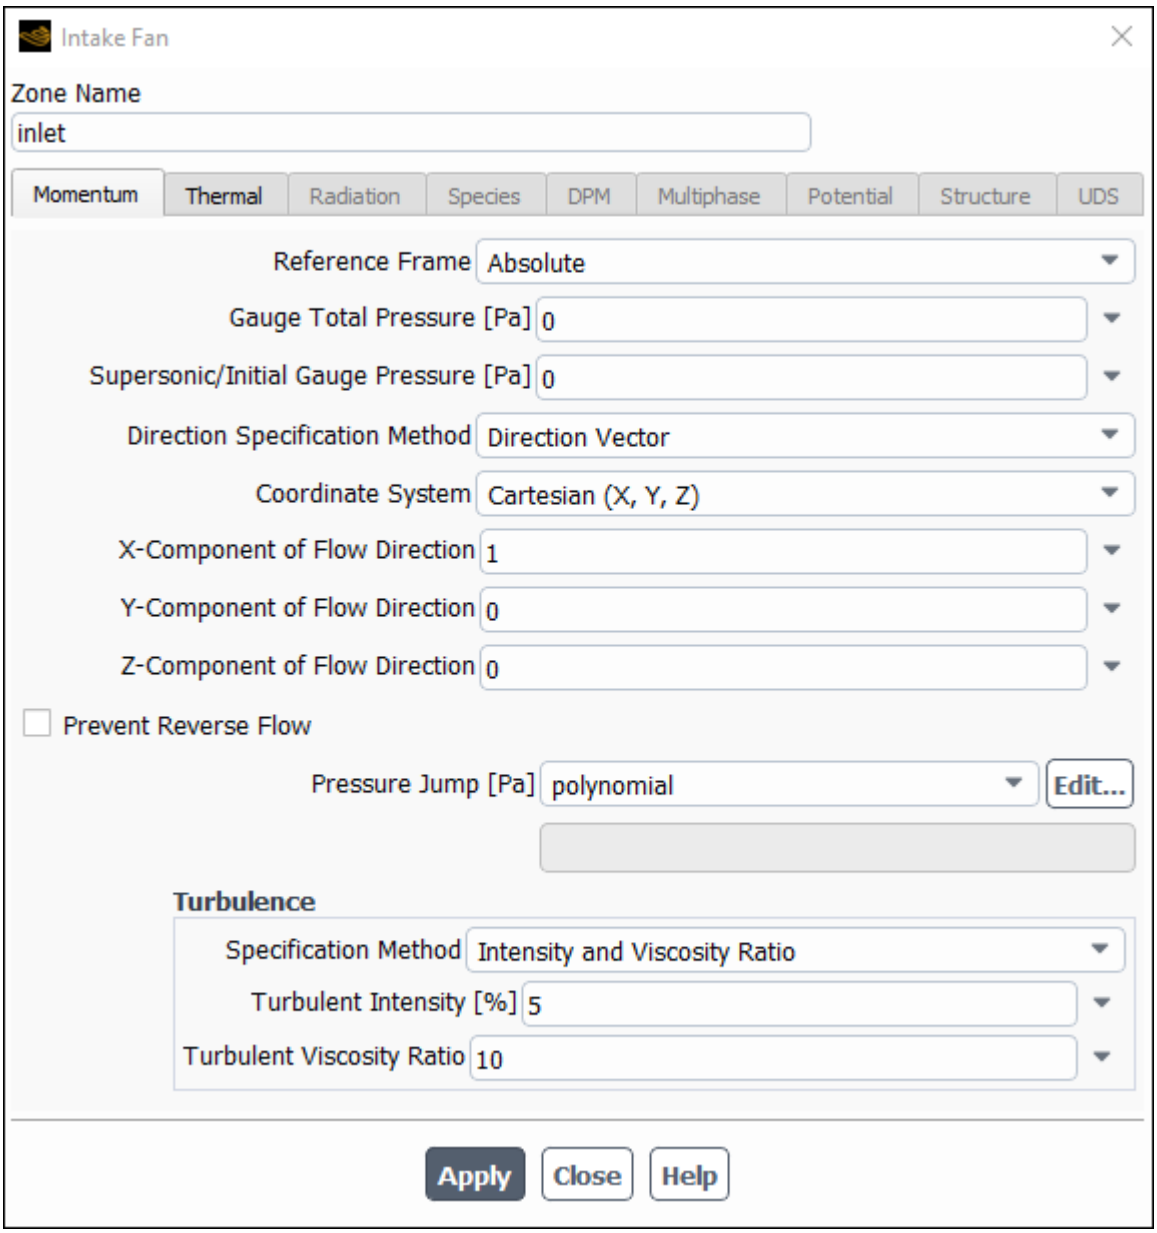
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- open channel flow parameters (for open channel flow calculations using the VOF multiphase model)

All values are entered in the Intake Fan Dialog Box (p. 4959) (shown in Figure 7.41: The Intake Fan Dialog Box (p. 1411)), which is opened from the **Boundary Conditions** task page (as described in Setting Cell Zone and Boundary Conditions (p. 1281)).

The first 12 items listed above are specified in the same way that they are specified at pressure inlet boundaries. See Inputs at Pressure Inlet Boundaries (p. 1380) for details. Specification of the pressure jump is described here. Open channel boundary condition inputs are described in Modeling Open Channel Flows (p. 2975).

Figure 7.41: The Intake Fan Dialog Box



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.8.1.1. Specifying the Pressure Jump

An intake fan is considered to be infinitely thin, and the discontinuous pressure rise across it is specified as a function of the velocity through the fan. In the case of reversed flow, the fan is treated like an outlet vent with a loss coefficient of unity.

You can define the **Pressure-Jump** across the fan as a **constant**, **polynomial**, **piecewise-linear**, or **piecewise-polynomial** function of the normal velocity. The dialog boxes for defining these functions are the same as those used for defining temperature-dependent properties. See Defining Properties Using Temperature-Dependent Functions (p. 1590) for details.

7.4.9. Pressure Outlet Boundary Conditions

Pressure outlet boundary conditions require the specification of a static (gauge) pressure at the outlet boundary. The value of the specified static pressure is used only while the flow is subsonic. Should the flow become locally supersonic, the specified pressure will no longer be used; pressure will be extrapolated from the flow in the interior. All other flow quantities are extrapolated from the interior.

A set of "backflow" conditions is also specified should the flow reverse direction at the pressure outlet boundary during the solution process. Convergence difficulties will be minimized if you specify realistic values for the backflow quantities.

Several options in Ansys Fluent exist, where a radial equilibrium outlet boundary condition can be used (see Defining Static Pressure (p. 1414) and a target mass flow rate for pressure outlets (see Target Mass Flow Rate Option (p. 1420) for details) can be specified.

For an overview of flow boundaries, see Flow Inlet and Exit Boundary Conditions (p. 1372).

7.4.9.1. Inputs at Pressure Outlet Boundaries

7.4.9.1.1. Summary

You will enter or select the following information for a pressure outlet boundary:

- static pressure
- pressure profile multiplier
- backflow conditions
  - total (stagnation) temperature (for energy calculations)
  - backflow pressure specification
  - backflow direction specification method
  - turbulence parameters (for turbulent calculations)
  - chemical species mass or mole fractions (for species calculations)
  - mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
  - progress variable (for premixed or partially premixed combustion calculations)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

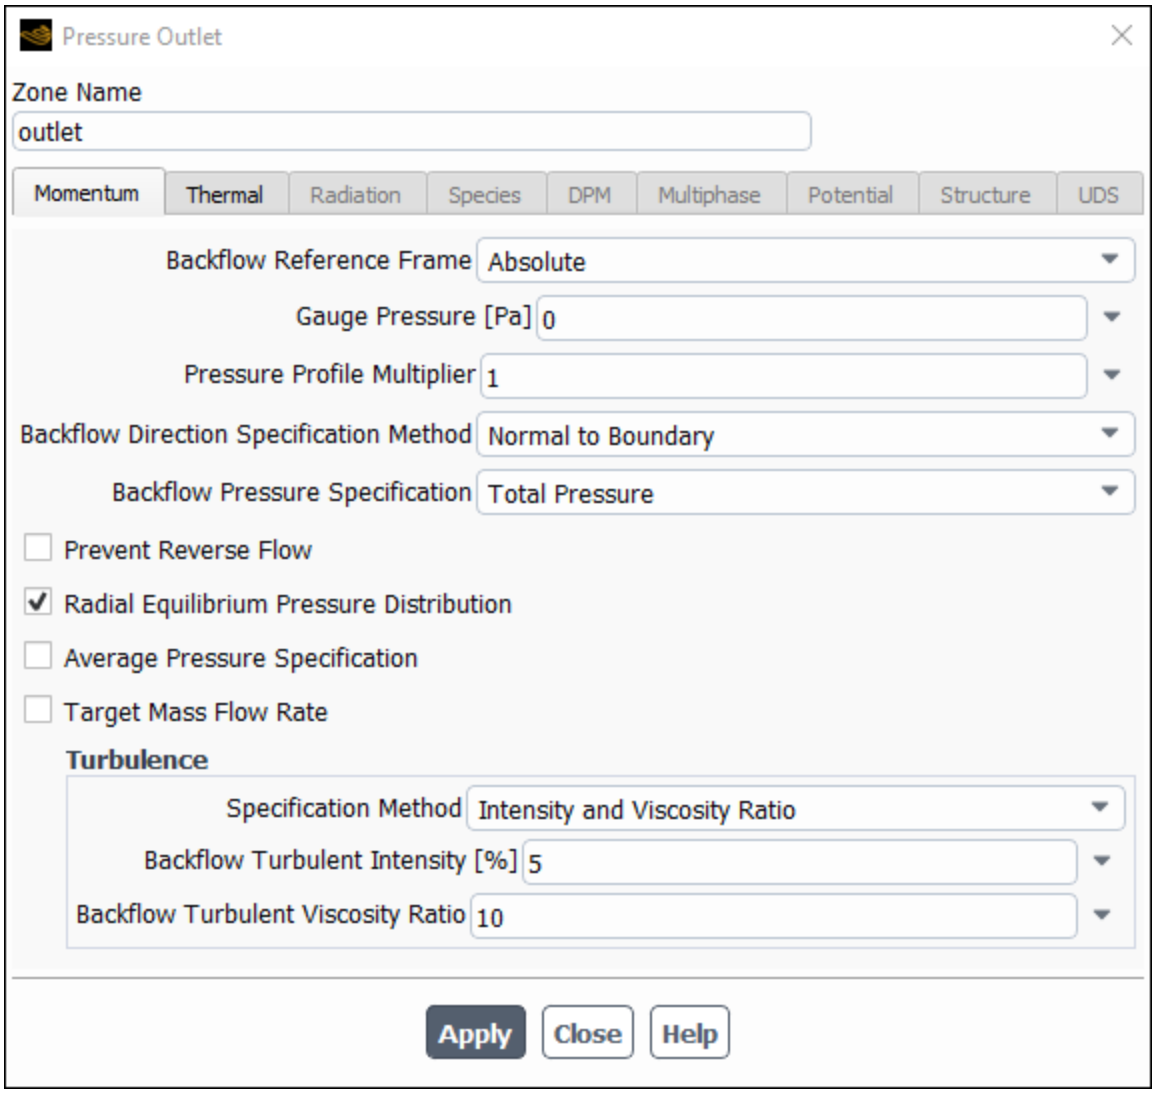
  - multiphase boundary conditions (for general multiphase calculations)
  - type of backflow reference frame (not available for multiphase flows or with the acoustic wave model)

- radiation parameters (for calculations using the P-1, DTRM, DO, surface-to-surface, or MC models)
- discrete phase boundary conditions (for discrete phase calculations)
- open channel flow parameters (for open channel flow calculations using the VOF multiphase model)
- radial equilibrium pressure distribution
- average pressure specification (not available for multiphase flows)
- target mass flow rate (not available for multiphase flows)
- acoustic wave model settings

All values are entered in the Pressure Outlet Dialog Box (p. 5006) (Figure 7.42: The Pressure Outlet Dialog Box (p. 1414)), which is opened from the **Boundary Conditions** task page (as described in Setting Cell Zone and Boundary Conditions (p. 1281)). Note that open channel boundary condition inputs are described in Modeling Open Channel Flows (p. 2975), and acoustic wave model settings are described in Boundary Acoustic Wave Models (p. 1503).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.42: The Pressure Outlet Dialog Box



7.4.9.1.2. Defining Static Pressure

To set the static pressure at the pressure outlet boundary, enter the appropriate value for **Gauge Pressure** in the **Pressure Outlet** dialog box. This value will be used when the flow is locally subsonic. Should the flow become locally supersonic, the pressure will be extrapolated from the upstream conditions. By default the subsonic and supersonic local flow condition at the boundary is determined based on the local normal velocity component.

Remember that the static pressure value you enter is relative to the operating pressure set in the Operating Conditions Dialog Box (p. 4926). Refer to Pressure Inputs and Hydrostatic Head (p. 1381) regarding hydrostatic pressure.

Ansys Fluent also provides an option to use a radial equilibrium outlet boundary condition. This option is used to model the exit flow in turbomachinery flow problems. To turn on this option, enable **Radial Equilibrium Pressure Distribution**. When this feature is active, the specified gauge pressure applies only to the position of minimum radius (relative to the axis of rotation) at the boundary. The static pressure on the rest of the zone is calculated from the assumption that radial velocity is negligible, so that the pressure gradient is given by

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\frac{\partial p}{\partial r} = \frac{\rho v_\theta^2}{r} \tag{7.104}$$

where r is the distance from the axis of rotation and v_θ is the tangential velocity. Note that this boundary condition can be used even if the rotational velocity is zero. For example, it could be applied to the calculation of the flow through an annulus containing guide vanes.

Important:

Note that the radial equilibrium outlet condition is available only for 3D and axisymmetric swirl calculations.

Ansys Fluent also provides an option to use an **Average Pressure Specification** method at the pressure outlet boundary. This option allows the pressure along the outlet boundary to vary, but maintain an average equivalent to the specified value in the **Gauge Pressure** input field. The pressure variation allowed in this boundary implementation slightly diminishes the reflectivity of the boundary as compared with the default uniform pressure specification. In the density-based solver two averaging methods are available, **Strong Averaging** and **Weak Averaging**. The average pressure specification in the pressure-based solver is the same as the strong pressure averaging in the density-based solver. For more details, see Calculation Procedure at Pressure Outlet Boundaries (p. 1417).

The **Pressure Profile Multiplier** allows you to specify a constant factor by which the **Gauge Pressure** is multiplied. This is provided mainly for cases where a non-uniform distribution of the static pressure at the pressure outlet boundary is specified by means of a profile file or a user-defined function. The scaling of an outlet profile with a multiplier can be convenient, for example, when computing a performance map for a turbomachine at different mass flow rates. The option will also work for a constant **Gauge Pressure** simply by scaling its value by a factor. This scaled pressure value will be used consistently when additional options are enabled in the **Pressure Outlet** dialog box; for example, when the **Radial Equilibrium Pressure Distribution** option is enabled, the scaled gauge pressure will be applied to the position of minimum radius (relative to the axis of rotation) at the boundary.

7.4.9.1.3. Defining Backflow Conditions

Backflow properties consistent with the models you are using will appear in the **Pressure Outlet** dialog box. The specified values will be used only if flow is pulled in through the outlet.

- The **Backflow Total Temperature** (in the **Thermal** tab) should be set for problems involving energy calculation.
- When the direction of the backflow re-entering the computational domain is known, and deemed to be relevant to the flow field solution, you can specify it choosing one of the options available in the **Backflow Direction Specification Method** drop-down list. The default value for this field is **Normal to Boundary**, and requires no further input. If you choose **Direction Vector**, the dialog box will expand to show the inputs for the components of the direction vector for the backflow, and if you are running the 3D version of Ansys Fluent, the dialog box will display a **Coordinate System** drop-down list. If you choose **From Neighboring Cell**, Ansys Fluent will determine the direction of the backflow using the direction of the flow in the cell layer adjacent to the pressure outlet.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- For turbulent calculations, there are several ways in which you can define the turbulence parameters. Instructions for deciding which method to use in determining appropriate values for these inputs are provided in Determining Turbulence Parameters (p. 1373). Turbulence modeling in general is described in Modeling Turbulence (p. 2025).

- If you are modeling species transport, you will set the backflow species mass or mole fractions under **Species Mass Fractions** or **Species Mole Fractions**. For details, see Defining Cell Zone and Boundary Conditions for Species (p. 2392).

- If you are modeling combustion using the non-premixed or partially premixed combustion model, you will set the backflow mixture fraction and variance values. See Defining Non-Premixed Boundary Conditions (p. 2524) for details.

- If you are modeling combustion using the premixed or partially premixed combustion model, you will set the backflow **Progress Variable** value. See Setting Boundary Conditions for the Progress Variable (p. 2539) for details.

- If you are using the VOF, mixture, or Eulerian model for multiphase flow, you will need to specify volume fractions for secondary phases and (for some models) additional parameters. See Defining Multiphase Cell Zone and Boundary Conditions (p. 2953) for details.

- If backflow occurs,

  1. The pressure you specified as the **Gauge Pressure** will be used to determine the total pressure or the static pressure (based on your selection from the **Backflow Pressure Specification** drop-down list), so you need not specify a backflow pressure value explicitly. When **Total Pressure** is selected for **Backflow Pressure Specification**, boundary face pressure values are calculated by combining the **Gauge Pressure** with a dynamic contribution that is based on the velocity in the adjacent cell zone; when **Static Pressure** is selected for **Backflow Pressure Specification**, the specified **Gauge Pressure** value is directly imposed as the boundary face pressure.

  2. The flow direction will be based on your selection from the **Backflow Direction Specification Method** drop-down list.

  3. The total temperature, total pressure, and flow directions are in *absolute* or *relative to the adjacent cell zone* reference frames, based on the **Backflow Reference Frame** setting specified in the **Pressure Outlet** dialog box.

  If the cell zone adjacent to the pressure outlet is moving (that is, if you are using a moving reference frame, multiple reference frames, mixing planes, or sliding meshes) and you are using the pressure-based solver, the velocity in the dynamic contribution to total pressure (see Equation 7.88 (p. 1382)) will be absolute or relative to the motion of the cell zone, depending on whether or not the **Absolute** velocity formulation is selected in the **General** task page. For the density-based solver, the velocity in Equation 7.88 (p. 1382) (or the Mach number in Equation 7.89 (p. 1382)) is always in the absolute frame.

Important:

Even if no backflow is expected in the converged solution, you should always set realistic values to minimize convergence difficulties in the event that backflow does occur during the calculation.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Backflow Reference Frame** option is not available for all multiphase models or non-reflecting boundary condition options.

7.4.9.1.3.1. Prevent Reverse Flow

When this option is selected, Fluent will erect artificial walls on the boundary mesh faces to prevent flow back into the domain. The artificial walls are removed when the flow is no longer entering the domain and when a favorable pressure gradient is recovered at the boundary mesh faces.

When artificial walls are created, Fluent will print a message in the console window indicating the number of faces on which artificial walls have been erected and the equivalent area percentage of the boundary it represents.

Note:

This feature is not available with multiphase flow.

7.4.9.1.4. Defining Radiation Parameters

The options available depend on which radiation model is active. For details, see Defining Boundary Conditions for Radiation (p. 2181).

7.4.9.1.5. Defining Discrete Phase Boundary Conditions

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the pressure outlet. See Setting Boundary Conditions for the Discrete Phase (p. 2776) for details.

7.4.9.1.6. Defining Open Channel Boundary Conditions

If you are using the VOF model for multiphase flow and modeling open channel flows, you will need to specify the **Free Surface Level**, **Bottom Level**, and additional parameters. See Modeling Open Channel Flows (p. 2975) for details.

7.4.9.2. Default Settings at Pressure Outlet Boundaries

Default settings (in SI) for pressure outlet boundary conditions are as follows:

Gauge Pressure	0
Pressure Profile Multiplier	1
Backflow Total Temperature	300
Backflow Turbulent Intensity	5%
Backflow Turbulent Viscosity Ratio	10

7.4.9.3. Calculation Procedure at Pressure Outlet Boundaries

At pressure outlets, if the flow exiting the boundary is subsonic, then Ansys Fluent uses the pressure specified in the **Pressure Outlet** dialog box as the static pressure of the fluid at the outlet plane,

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

P_s, and extrapolates all other conditions from the interior of the domain. However, if the flow exiting the boundary becomes supersonic, then the face pressure values are extrapolated from the interior cell pressure.

7.4.9.3.1. Average Pressure Specification

When this option is selected, the exit pressure is not kept constant over the pressure outlet boundary, but instead is allowed to vary across the boundary while maintaining an average boundary pressure close to the specified static exit pressure. This option can be used for pressure specified as a constant or as a profile (for example, in turbomachinery cases with radial, axial, or radial equilibrium pressure distributions).

There are two implementations of the **Average Pressure Specification**. These are **Strong Averaging** and **Weak Averaging**. The strong averaging approach is available in both the density-based and the pressure-based solver. The weak averaging approach is available only in the density-based solver.

Note:

- The **Average Pressure Specification** option is not available with multiphase flows.
- When using the density-based solver, **Strong Averaging** is the recommended method and is used by default. The weak averaging method is maintained primarily for legacy simulations.
- When one of the **Acoustic Wave Models** is active, the Average Pressure Specification option is not offered because the pressure will be obtained based on the **Acoustic Wave Model** chosen.
- Using the Average Pressure Specification option in unsteady simulations can result in nonphysical pressure feedback and is not recommended.

7.4.9.3.1.1. Strong Averaging

In the **Strong Averaging** approach, the face pressure value P_f for subsonic exit flow is computed using the following expression:

$$P_f = P_e + \left(1 - F\right)\left(P_c - P_{c_avg}\right) \tag{7.105}$$

where

P_c = interior cell pressure at neighboring exit face, f

P_{c_avg} = averaged interior cell pressure at a boundary

P_e = specified exit pressure

F = pressure blending factor; $F=0$ recovers the fully averaged pressure, $F=1$ recovers the specified pressure.

When the strong averaging option is used with a profile specification method (radial, axial, or radial equilibrium pressure distribution) then the outlet boundary will be subdivided into radial or axial containers called "bins", and the above averaging procedure is applied to each bin.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

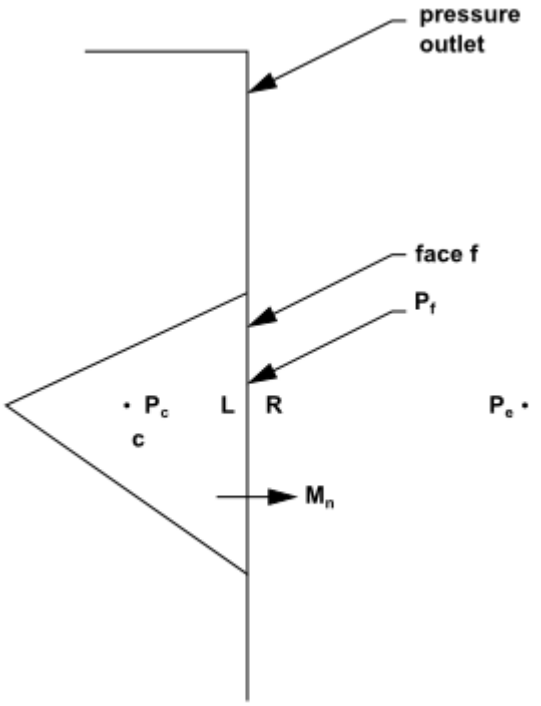
You can use the following TUI command to change the blending factor and the number of bins:

```
/define/boundary-conditions/bc-settings/pressure-outlet
```

7.4.9.3.1.2. Weak Averaging

When the weak averaging method is used and the flow is subsonic, the pressure at the faces of the outlet boundary is computed using a weighted average of the left and right state of the face boundary. This weighting is a blend of fifth-order polynomials based on the exit face normal Mach number [87] (p. 5660). Therefore, the face pressure P_f is a function of (P_c, P_e, M_n), where P_c is the interior cell pressure neighboring the exit face f, P_e is the specified exit pressure, and M_n is the face normal Mach number.

Figure 7.43: Pressures at the Face of a Pressure Outlet Boundary



For incompressible flows, the face pressure is computed as an average between the specified pressure and the interior pressure.

$$P_f = 0.5\left(P_c + P_e\right) \tag{7.106}$$

In this boundary implementation, the exit pressure is not constant along the pressure outlet boundary. However, upon flow convergence, the average boundary pressure will be close to the specified static exit pressure.

7.4.9.4. Other Optional Inputs at Pressure Outlet Boundaries

7.4.9.4.1. Non-Reflecting Boundary Conditions Option

One of the options that may be used at pressure outlets is non-reflecting boundary conditions (NRBC). This option is used when waves are made to pass through the boundaries while avoiding

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

false reflections. Details of non-reflecting boundary conditions can be found in General Non-Reflecting Boundary Conditions (p. 1514).

7.4.9.4.2. Target Mass Flow Rate Option

The simple Bernoulli's equation is used to adjust the pressure at every iteration on a pressure outlet zone in order to meet the desired mass flow rate. The change in pressure, based on Bernoulli's equation is given by the following equation:

$$dP = 0.5\rho_{ave}\left(\dot{m}^2 - \dot{m}_{req}^2\right) / \left(\rho_{ave}A\right)^2 \tag{7.107}$$

where dP is the change in pressure, $\dot{m}$ is the current computed mass flow rate at the pressure-outlet boundary, $\dot{m}_{req}$ is the required mass flow rate, ρ_{ave} is the computed average density at the pressure-outlet boundary, and A is the area of the pressure-outlet boundary.

Limitations

- The target mass flow rate option is not available with multiphase flows or when any of the non-reflecting boundary conditions models are used.
- If the pressure-outlet zone is used in the mixing-plane model, the target mass flow rate option will not be available for that particular zone.
- The pressure outlet will not achieve the target mass flow rate if the flow becomes choked (that is, the Mach number of the fluid in the pressure-outlet zone becomes equal to 1).
- The pressure outlet may not achieve the target mass flow rate if porous zones are present in the flow domain causing a large pressure drop.

Target Mass Flow Rate Settings

To use the target mass flow rate option

1. Enable **Target Mass Flow Rate** in the **Pressure Outlet** dialog box.
2. Specify the **Target Mass Flow** as either a constant value or hook a UDF to set the target mass flow rate.

   The settings for the target mass flow rate option can be accessed from the `target-mass-flow-rate-settings` text command:

   `define` → `boundary-conditions` → `target-mass-flow-rate-settings`

   You will be prompted to

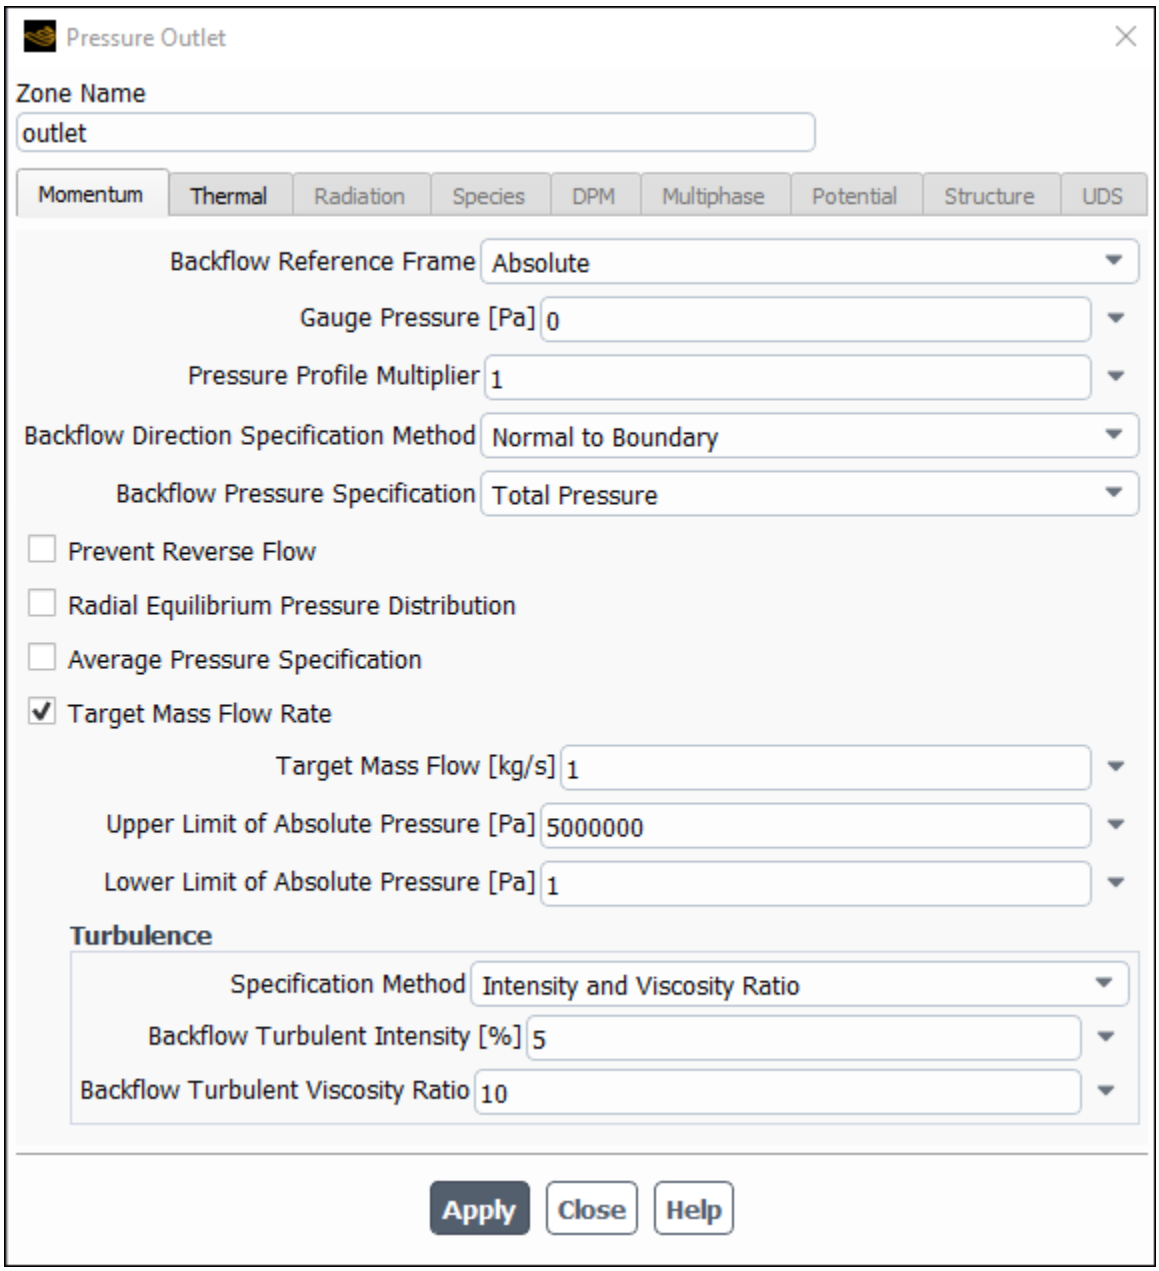
   a. Set the under-relaxation factor (the default setting is 0.05).

   b. Enable the targeted mass flow rate verbosity (the default is `no`). If enabled, it prints to the console window the required mass flow rate, computed mass flow rate, mean pressure, the new pressure imposed on the outlet, and the change in pressure in SI units.
3. In the **Pressure Outlet** dialog box, specify the **Upper Limit of Absolute Pressure** and **Lower Limit of Absolute Pressure**. Specifying the range of the pressure limits improves convergence in cases with a large number of outlet boundaries, which have different pressure variations

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

on different boundaries. You can also use the `define/boundary-conditions/pressure-outlet` text command to specify these limits.

Figure 7.44: The Pressure Outlet Dialog Box with the Target Mass Flow Rate Option Enabled



Solution Strategies When Using the Target Mass Flow Rate Option

If convergence difficulties are encountered or if the solution is not converging at the desired mass flow rate, then try to lower the under-relaxation factor from the default value. Otherwise, you can use the alternate method to converge at the required mass flow rate.

In some cases, you may want to switch off the target mass flow rate option initially, then guess an exit pressure that will bring the solution closer to the target mass flow rate. After the solution stabilizes, you can turn on the target mass flow rate option and iterate to convergence. For many complex flow problems, this strategy is usually very successful.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The use of Full Multigrid Initialization is also very helpful in obtaining a good starting solution and in general will reduce the time required to get a converged solution on a target mass flow rate. For further information on Full Multigrid Initialization, see Full Multigrid (FMG) Initialization (p. 3619).

Setting Target Mass Flow Rates Using UDFs

For some unsteady problems it is desirable that the target mass flow rate be a function of the physical flow time. This enforcement of boundary condition can be done by attaching a UDF with `DEFINE_PROFILE` functions to the target mass flow rate field.

Important:

Note that the mass flow rate profile is a function of time and only one constant value should be applied to all zone faces at a given time.

An example of a simple UDF using a `DEFINE_PROFILE` that will adjust the mass flow rate can be found in `DEFINE_PROFILE` in the Fluent Customization Manual.

7.4.10. Pressure Far-Field Boundary Conditions

Pressure far-field conditions are used in Ansys Fluent to model a free-stream condition at infinity, with free-stream Mach number and static conditions being specified. The pressure far-field boundary condition is often called a characteristic boundary condition, since it uses characteristic information (Riemann invariants) to determine the flow variables at the boundaries.

7.4.10.1. Limitations

Note the following limitations and restrictions when using pressure far-field boundary conditions:

- This boundary condition is applicable only when the density is calculated using the ideal-gas law (see Density (p. 1598)). Using it for other flows is not permitted. To effectively approximate true infinite-extent conditions, you must place the far-field boundary far enough from the object of interest. For example, in lifting airfoil calculations, it is not uncommon for the far-field boundary to be a circle with a radius of 20 chord lengths.
- It is incompatible with the multiphase models (VOF, mixture, and Eulerian) that are available with the pressure-based solver.
- It cannot be applied to flows that employ constant density, the real gas model, and the wet steam model, which are available in the density-based solver.

For an overview of flow boundaries, see Flow Inlet and Exit Boundary Conditions (p. 1372).

7.4.10.2. Inputs at Pressure Far-Field Boundaries

7.4.10.2.1. Summary

You will enter the following information for a pressure far-field boundary:

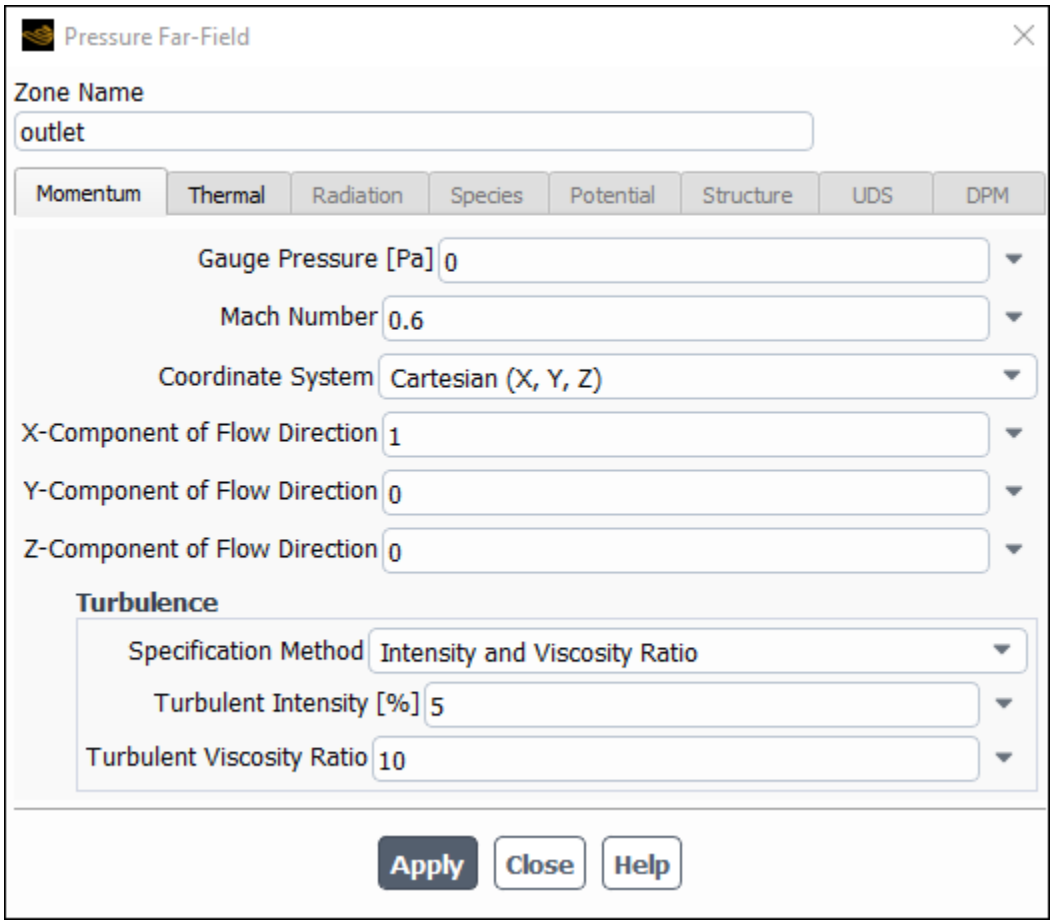
- static pressure

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Mach number
- temperature
- flow direction
- turbulence parameters (for turbulent calculations)
- radiation parameters (for calculations using the P-1, DTRM, DO, surface-to-surface, or MC models)
- chemical species mass or mole fractions (for species calculations)
- discrete phase boundary conditions (for discrete phase calculations)

All values are entered in the Pressure Far-Field Dialog Box (p. 4991) (Figure 7.45: The Pressure Far-Field Dialog Box (p. 1423)), which is opened from the **Boundary Conditions** task page (as described in Setting Cell Zone and Boundary Conditions (p. 1281)).

Figure 7.45: The Pressure Far-Field Dialog Box



7.4.10.2.2. Defining Static Pressure, Mach Number, and Static Temperature

To set the static pressure and temperature at the far-field boundary in the **Pressure Far-Field** dialog box, enter the appropriate values for **Gauge Pressure** and **Mach Number** in the **Momentum**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

tab. The Mach number can be subsonic, sonic, or supersonic. Set the **Temperature** in the **Thermal** tab.

7.4.10.2.3. Defining the Flow Direction

You can define the flow direction at a pressure far-field boundary by setting the components of the direction vector. If your geometry is 2D non-axisymmetric enter appropriate values for **X** and **Y** in the **Pressure Far-Field** dialog box (Figure 7.45: The Pressure Far-Field Dialog Box (p. 1423)). If your geometry is 2D axisymmetric, enter the appropriate values for **Axial**, **Radial**, and (if you are modeling axisymmetric swirl) **Tangential-Component of Flow Direction**.

If your geometry is 3D, you can choose a **Coordinate System** that is **Cartesian**, **Cylindrical**, or **Local Cylindrical**. In the Cartesian coordinate system, enter the appropriate values for **X**, **Y**, and **Z-Component of Flow Direction**. If the direction cosine data on the boundary is available, then use the cylindrical or local cylindrical coordinate system and specify the **Axial**, **Radial**, **Tangential-Component of Flow Direction**. For **Cylindrical**, axis parameters need to be specified on the adjacent cell zone of the boundary face. For **Local Cylindrical Swirl**, specify the **Axis Origin** and **Axis Direction**.

7.4.10.2.4. Defining Turbulence Parameters

For turbulent calculations, there are several ways in which you can define the turbulence parameters. Instructions for deciding which method to use and determining appropriate values for these inputs are provided in Determining Turbulence Parameters (p. 1373). Turbulence modeling is described in Modeling Turbulence (p. 2025).

7.4.10.2.5. Defining Radiation Parameters

The options available depend on which radiation model is active. For details, see Defining Boundary Conditions for Radiation (p. 2181).

7.4.10.2.6. Defining Species Transport Parameters

If you are modeling species transport, you will set the species mass or mole fractions under **Species Mass Fractions** or **Species Mole Fractions**. See Defining Cell Zone and Boundary Conditions for Species (p. 2392) for details.

7.4.10.3. Defining Discrete Phase Boundary Conditions

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the pressure far-field boundary. See Setting Boundary Conditions for the Discrete Phase (p. 2776) for details.

7.4.10.4. Default Settings at Pressure Far-Field Boundaries

Default settings (in SI) for pressure far-field boundary conditions are as follows:

Gauge Pressure	0
Mach Number	0.6
Temperature	300
X-Component of Flow Direction	1

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Y-Component of Flow Direction	0
Z-Component of Flow Direction	0
Turbulent Intensity	5%
Turbulent Viscosity Ratio	10

7.4.10.5. Calculation Procedure at Pressure Far-Field Boundaries

The pressure far-field boundary condition is a non-reflecting boundary condition based on the introduction of Riemann invariants (that is, characteristic variables) for a one-dimensional flow normal to the boundary. For flow that is subsonic there are two Riemann invariants, corresponding to incoming and outgoing waves:

$$R_{\infty}=v_{n_{\infty}}-\frac{2c_{\infty}}{\gamma-1} \tag{7.108}$$

$$R_i=v_{n_i}+\frac{2c_i}{\gamma-1} \tag{7.109}$$

where v_n is the velocity magnitude normal to the boundary, c is the local speed of sound and γ is the ratio of specific heats (ideal gas). The subscript ∞ refers to conditions being applied at infinity (the boundary conditions), and the subscript i refers to conditions in the interior of the domain (that is, in the cell adjacent to the boundary face). These two invariants can be added and subtracted to give the following two equations:

$$v_n=\frac{1}{2}\left(R_i+R_{\infty}\right) \tag{7.110}$$

$$c=\frac{\gamma-1}{4}\left(R_i-R_{\infty}\right) \tag{7.111}$$

where v_n and c become the values of normal velocity and sound speed applied on the boundary. At a face through which flow exits, the tangential velocity components and entropy are extrapolated from the interior; at an inflow face, these are specified as having free-stream values. Using the values for v_n, c, tangential velocity components, and entropy the values of density, velocity, temperature, and pressure at the boundary face can be calculated.

7.4.10.6. Flux-based Pressure Far-Field

Fluent's density-based solver offers an alternative method for the pressure far-field boundary condition. This method employs a Riemann solver to evaluate the numerical flux at the far-field boundary, thus providing the same level of accuracy and robustness as the interior faces. This treatment is a global application of the local tangency-correction used to regain robustness on boundary faces tangent to the imposed flow direction (as described in Tangency Correction (p. 1426)). It is also advantageous for calculations where boundary layers or wakes extend beyond the boundary of the computational domain. This flux-based pressure far-field can be selected with the following text command:

```
/define/boundary-condition/bc-settings/pressure-far-field/type?
```

Following the prompts, enter **1** for `Flux-based`.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.10.7. Tangency Correction

Depending on the choice of computational domain, certain boundary-faces might be tangent to the imposed free-stream flow direction. Flow tangency along a pressure far-field boundary hinders the solver robustness. To regain robustness in such situations, a local tangency-correction has been implemented in Fluent's density-based solver. This correction locally replaces the standard Riemann-invariants boundary treatment by a numerical-flux evaluation, analogous to using a Riemann solver. The correction is active by default, and can be deactivated with the following text command:

```
/define/boundary-condition/bc-settings/pressure-far-field/riemann-in-
variants-tangency-correction?
```

7.4.11. Outflow Boundary Conditions

Outflow boundary conditions in Ansys Fluent are used to model flow exits where the details of the flow velocity and pressure are not known prior to solving the flow problem. You do not define any conditions at outflow boundaries (unless you are modeling radiative heat transfer, a discrete phase of particles, or split mass flow): Ansys Fluent extrapolates the required information from the interior. It is important, however, to understand the limitations of this boundary type.

Important:

Note that outflow boundaries cannot be used in the following cases:

- If a problem includes pressure inlet boundaries; use pressure outlet boundary conditions (see Pressure Outlet Boundary Conditions (p. 1412)) instead.
- If you are modeling compressible flow.
- If you are modeling unsteady flows with varying density (even if the fluid is incompressible), it is preferable to use a pressure outlet.

In general, an outflow condition may be used in incompressible cases using the Eulerian or Mixture multiphase models. However, if the flow may produce a recirculation at the outlet or if the flow field is not stable and fully developed at the outlet, then a pressure outlet boundary condition is preferred.

For an overview of flow boundaries, see Flow Inlet and Exit Boundary Conditions (p. 1372).

7.4.11.1. Ansys Fluent's Treatment at Outflow Boundaries

The boundary conditions used by Ansys Fluent at outflow boundaries are as follows:

- A zero diffusion flux for all flow variables.
- An overall mass balance correction.

The zero diffusion flux condition applied at outflow cells means that the conditions of the outflow plane are extrapolated from within the domain and have no impact on the upstream flow. The extrapolation procedure used by Ansys Fluent updates the outflow velocity and pressure in a

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

manner that is consistent with a fully-developed flow assumption, as noted below, when there is no area change at the outflow boundary.

The zero diffusion flux condition applied by Ansys Fluent at outflow boundaries is approached physically in fully-developed flows. Fully-developed flows are flows in which the flow velocity profile (and/or profiles of other properties such as temperature) is unchanging in the flow direction.

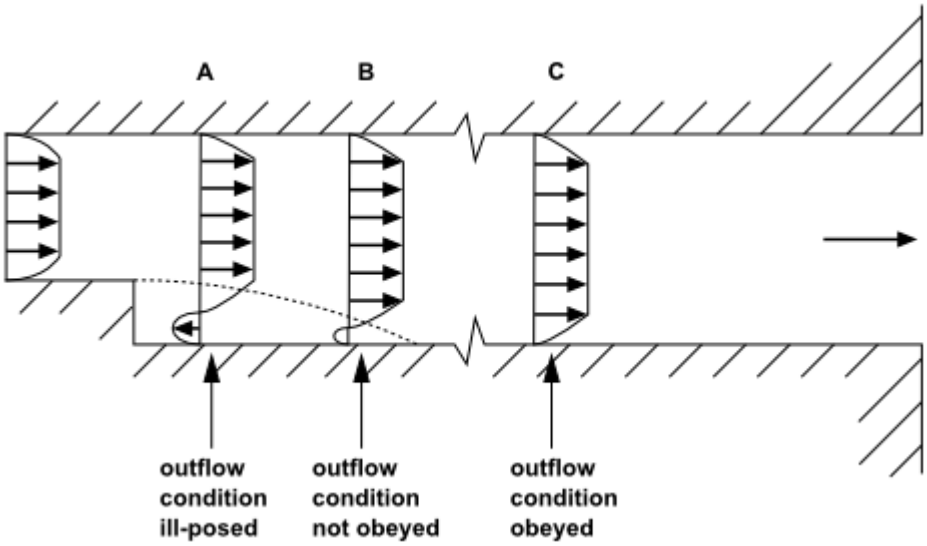
It is important to note that gradients in the cross-stream direction may exist at an outflow boundary. Only the diffusion fluxes in the direction normal to the exit plane are assumed to be zero.

7.4.11.2. Using Outflow Boundaries

As noted in Ansys Fluent's Treatment at Outflow Boundaries (p. 1426), the outflow boundary condition is obeyed in fully-developed flows where the diffusion flux for all flow variables in the exit direction are zero. However, you may also define outflow boundaries at physical boundaries where the flow is not fully developed—and you can do so with confidence if the assumption of a zero diffusion flux at the exit is expected to have a small impact on your flow solution. The appropriate placement of an outflow boundary is described by example below.

- Outflow boundaries where normal gradients are negligible: Figure 7.46: Choice of the Outflow Boundary Condition Location (p. 1427) shows a simple two-dimensional flow problem and several possible outflow boundary location choices. Location C shows the outflow boundary located upstream of the plenum exit but in a region of the duct where the flow is fully-developed. At this location, the outflow boundary condition is exactly obeyed.

  Figure 7.46: Choice of the Outflow Boundary Condition Location



- Ill-posed outflow boundaries: Location B in Figure 7.46: Choice of the Outflow Boundary Condition Location (p. 1427) shows the outflow boundary near the reattachment point of the recirculation in the wake of the backward-facing step. This choice of outflow boundary condition is ill-posed as the gradients normal to the exit plane are quite large at this point and can be expected to have a significant impact on the flow field upstream. Because the outflow boundary condition ignores these axial gradients in the flow, location B is a poor choice for an outflow boundary. The exit location should be moved downstream from the reattachment point.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.46: Choice of the Outflow Boundary Condition Location (p. 1427) shows a second ill-posed outflow boundary at location A. Here, the outflow is located where flow is pulled into the Ansys Fluent domain through the outflow boundary. In situations like this the Ansys Fluent calculation typically does not converge and the results of the calculation have no validity. This is because when flow is pulled into the domain through an outflow, the mass flow rate through the domain is "floating" or undefined. In addition, when flow enters the domain through an outflow boundary, the scalar properties of the flow are not defined. For example, the temperature of the flow pulled in through the outflow is not defined. (Ansys Fluent chooses the temperature using the temperature of the fluid adjacent to the outflow, inside the domain.) Therefore you should view all calculations that involve flow entering the domain through an outflow boundary with skepticism. For such calculations, pressure outlet boundary conditions (see Pressure Outlet Boundary Conditions (p. 1412)) are recommended.

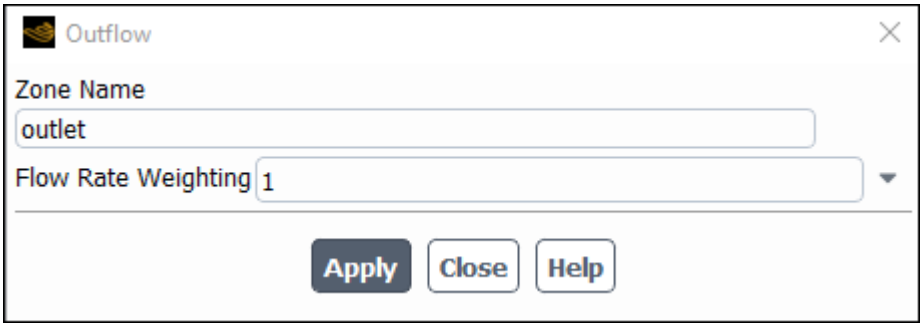
Important:

Note that convergence may be affected if there is recirculation through the outflow boundary at any point during the calculation, even if the final solution is not expected to have any flow reentering the domain. This is particularly true of turbulent flow simulations.

7.4.11.3. Mass Flow Split Boundary Conditions

In Ansys Fluent, it is possible to use multiple outflow boundaries and specify the fractional flow rate through each boundary. In the Outflow Dialog Box (p. 4979), set the **Flow Rate Weighting** to indicate what portion of the outflow is through the boundary.

Figure 7.47: The Outflow Dialog Box



The **Flow Rate Weighting** is a weighting factor:

$$\text{percentage flow through boundary} = \frac{\text{Flow Rate Weighting specified on boundary}}{\text{sum of all Flow Rate Weightings}} \tag{7.112}$$

By default, the **Flow Rate Weighting** for all outflow boundaries is set to 1. If the flow is divided equally among all of your outflow boundaries (or if you have just one outflow boundary), you need not change the settings from the default; Ansys Fluent will scale the flow rate fractions to obtain equal fractions through all outflow boundaries. Therefore, if you have two outflow boundaries and you want half of the flow to exit through each one, no inputs are required from you. If, however,

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

you want 75% of the flow to exit through one, and 25% through the other, you will need to explicitly specify *both* **Flow Rate Weighting** values, that is, 0.75 for one boundary and 0.25 for the other.

Important:

If you specify a **Flow Rate Weighting** of 0.75 at the first exit and leave the default **Flow Rate Weighting** (1.0) at the second exit, then the flow through each boundary will be

$$\text{Boundary 1} = \frac{0.75}{0.75+1.0} = 0.429 \text{ or } 42.9\%$$

$$\text{Boundary 2} = \frac{1.0}{0.75+1.0} = 0.571 \text{ or } 57.1\%$$

7.4.11.4. Other Inputs at Outflow Boundaries

7.4.11.4.1. Radiation Inputs at Outflow Boundaries

In general, there are no boundary conditions for you to set at an outflow boundary. If, however, you are using the P-1, DTRM, DO, surface-to-surface, or MC models, you will set the **Internal Emissivity** and (optionally) **External Black Body Temperature Method** in the **Outflow** dialog box. These parameters are described in Defining Boundary Conditions for Radiation (p. 2181). The default value for **Internal Emissivity** is 1 and the default value for **Black Body Temperature** is 300.

7.4.11.4.2. Defining Discrete Phase Boundary Conditions

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the outflow boundary. See Setting Boundary Conditions for the Discrete Phase (p. 2776) for details.

7.4.12. Outlet Vent Boundary Conditions

Outlet vent boundary conditions are used to model an outlet vent with a specified loss coefficient and ambient (discharge) pressure and temperature.

7.4.12.1. Inputs at Outlet Vent Boundaries

You will enter the following information for an outlet vent boundary:

- static pressure
- backflow conditions
  - total (stagnation) temperature (for energy calculations)
  - backflow pressure specification
  - backflow direction specification method
  - turbulence parameters (for turbulent calculations)
  - chemical species mass or mole fractions (for species calculations)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

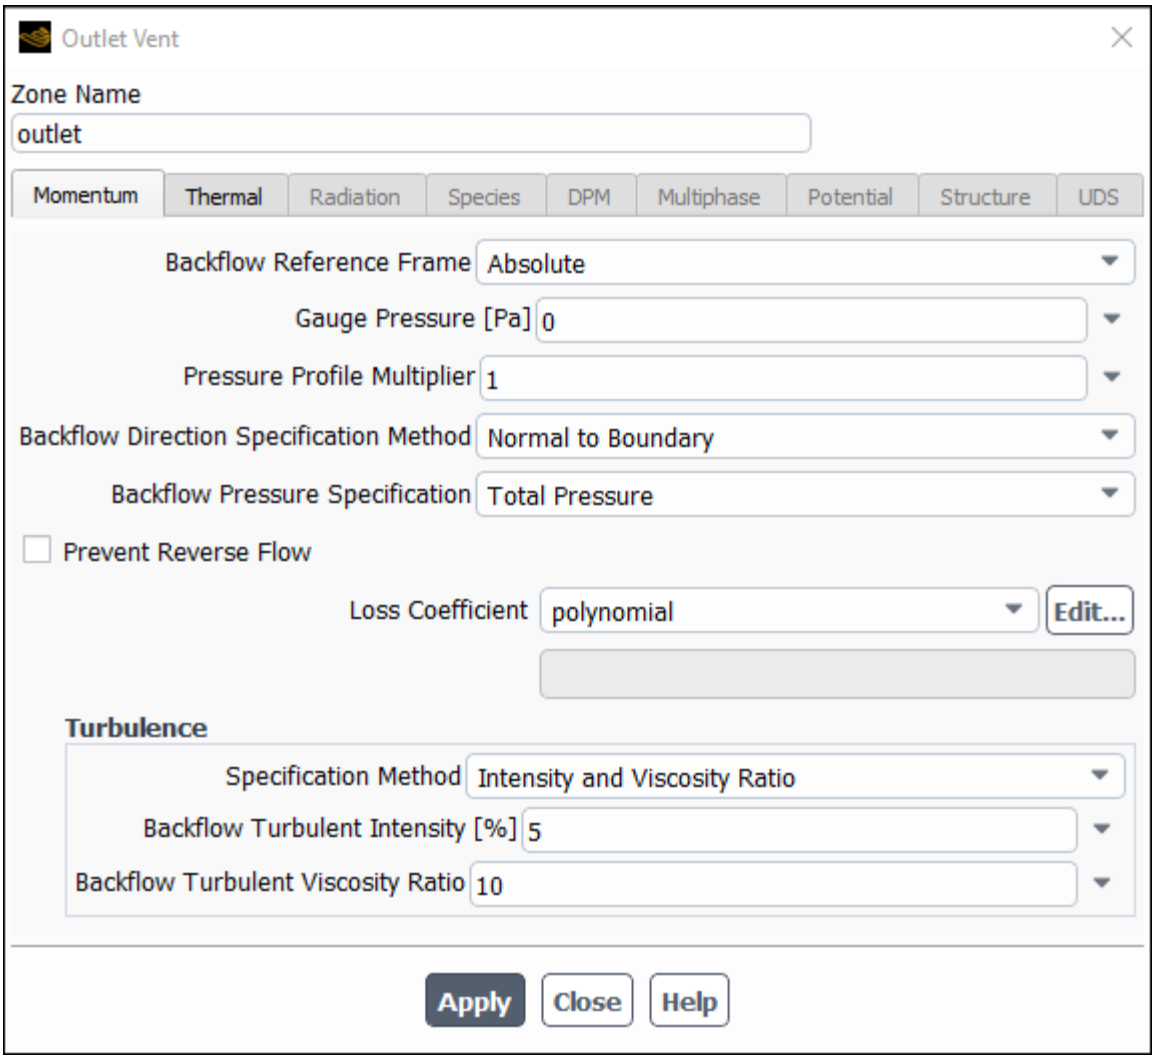
  - mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
  - progress variable (for premixed or partially premixed combustion calculations)
  - multiphase boundary conditions (for general multiphase calculations)
  - type of backflow reference frame (not available for multiphase flows)
- radiation parameters (for calculations using the P-1, DTRM, DO, surface-to-surface, or MC models)
- discrete phase boundary conditions (for discrete phase calculations)
- loss coefficient
- open channel flow parameters (for open channel flow calculations using the VOF multiphase model)

All values are entered in the Outlet Vent Dialog Box (p. 4981) (Figure 7.48: The Outlet Vent Dialog Box (p. 1431)), which is opened from the **Boundary Conditions** task page (as described in Setting Cell Zone and Boundary Conditions (p. 1281)).

The first 4 items listed above are specified in the same way that they are specified at pressure outlet boundaries. See Inputs at Pressure Outlet Boundaries (p. 1412) for details. Specification of the loss coefficient is described here. Open channel boundary condition inputs are described in Modeling Open Channel Flows (p. 2975).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.48: The Outlet Vent Dialog Box



7.4.12.1.1. Specifying the Loss Coefficient

An outlet vent is considered to be infinitely thin, and the pressure drop through the vent is assumed to be proportional to the dynamic head of the fluid, with an empirically determined loss coefficient that you supply. That is, the pressure drop, Δp, varies with the normal component of velocity through the vent, v, as follows:

$$\Delta p = k_L \frac{1}{2} \rho v^2 \tag{7.113}$$

where ρ is the fluid density, and k_L is the nondimensional loss coefficient.

Important:

Δp is the pressure drop in the direction of the flow; therefore the vent will appear as a resistance even in the case of backflow.

You can define a **constant**, **polynomial**, **piecewise-linear**, or **piecewise-polynomial** function for the **Loss Coefficient** across the vent. The dialog boxes for defining these functions are the

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

same as those used for defining temperature-dependent properties. See Defining Properties Using Temperature-Dependent Functions (p. 1590) for details.

7.4.13. Exhaust Fan Boundary Conditions

Exhaust fan boundary conditions are used to model an external exhaust fan with a specified pressure jump and ambient (discharge) pressure.

Note:

The exhaust fan boundary condition considers only momentum. Diffusion processes are not considered.

7.4.13.1. Inputs at Exhaust Fan Boundaries

You will enter the following information for an exhaust fan boundary:

- static pressure
- backflow conditions
  - total (stagnation) temperature (for energy calculations)
  - backflow pressure specification
  - backflow direction specification method
  - turbulence parameters (for turbulent calculations)
  - chemical species mass or mole fractions (for species calculations)
  - mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
  - progress variable (for premixed or partially premixed combustion calculations)
  - multiphase boundary conditions (for general multiphase calculations)
  - type of backflow reference frame (not available for multiphase flows)
  - user-defined scalar boundary conditions (for user-defined scalar calculations)
- radiation parameters (for calculations using the P-1, DTRM, DO, surface-to-surface, or MC models)
- discrete phase boundary conditions (for discrete phase calculations)
- pressure jump
- open channel flow parameters (for open channel flow calculations using the VOF multiphase model)

All values are entered in the Exhaust Fan Dialog Box (p. 4941) (Figure 7.49: The Exhaust Fan Dialog Box (p. 1434)), which is opened from the **Boundary Conditions** task page (as described in Setting Cell Zone and Boundary Conditions (p. 1281)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

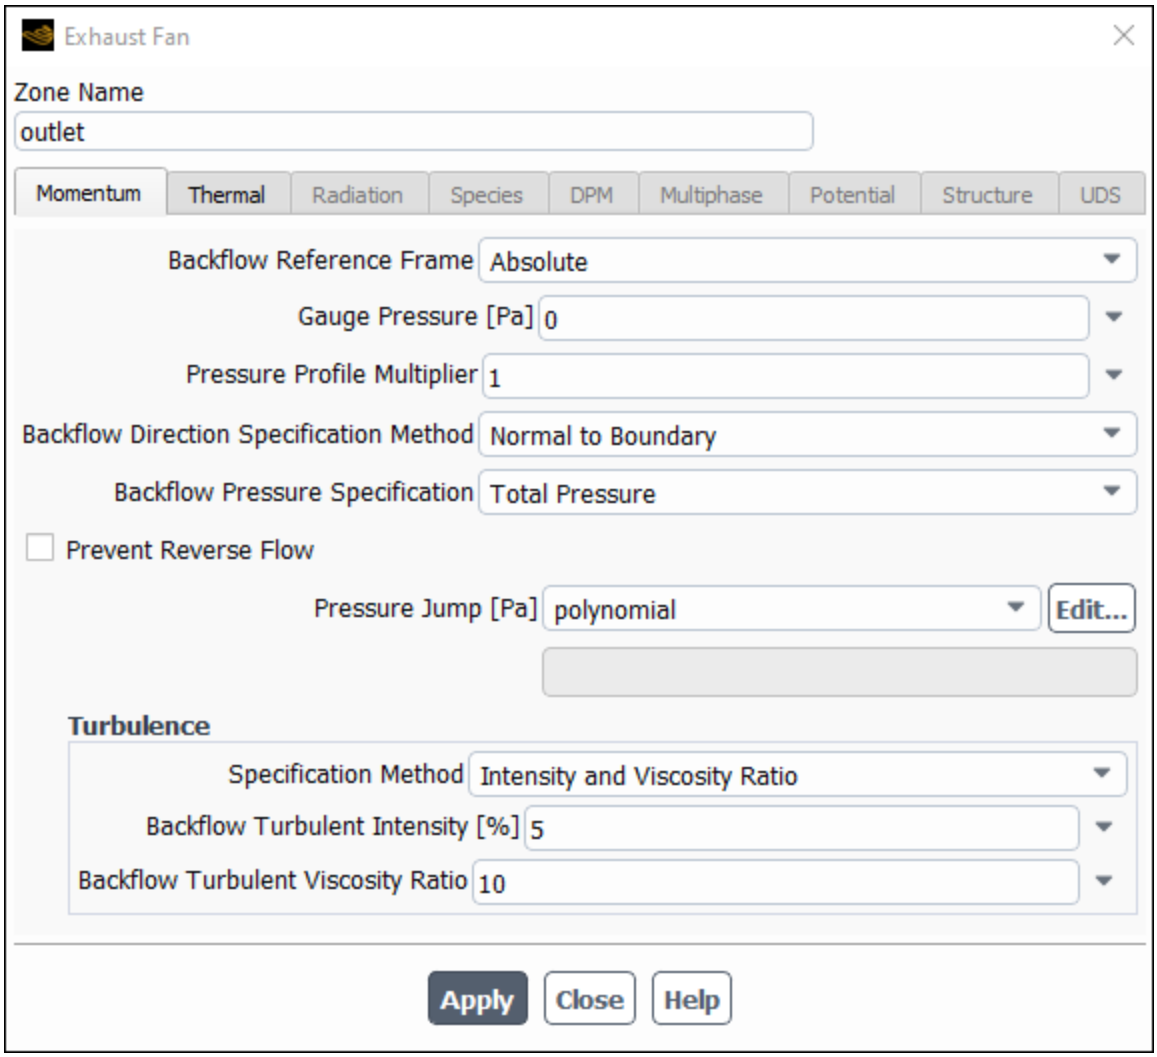
The first 4 items listed above are specified in the same way that they are specified at pressure outlet boundaries. See Inputs at Pressure Outlet Boundaries (p. 1412) for details. Specification of the pressure jump is described here. Open channel boundary condition inputs are described in Modeling Open Channel Flows (p. 2975).

7.4.13.1.1. Specifying the Pressure Jump

An exhaust fan is considered to be infinitely thin, and the discontinuous pressure rise across it is specified as a function of the local fluid velocity normal to the fan. You can define a **constant**, **polynomial**, **piecewise-linear**, or **piecewise-polynomial** function for the **Pressure Jump** across the fan. The dialog boxes for defining these functions are the same as those used for defining temperature-dependent properties. See Defining Properties Using Temperature-Dependent Functions (p. 1590) for details.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.49: The Exhaust Fan Dialog Box



Important:

You must be careful to model the exhaust fan so that a pressure rise occurs for forward flow through the fan. In the case of reversed flow, the fan is treated like an inlet vent with a loss coefficient of unity.

7.4.14. Degassing Boundary Conditions

Degassing boundary conditions are used to model a free surface through which dispersed gas bubbles are allowed to escape, but the continuous phase is not. A typical application is a bubble column in which you want to reduce computational cost by not including the freeboard region in the simulation.

When the degassing boundary condition is specified for an outlet, the continuous liquid phase sees the boundary as a free-slip wall and does not leave the domain. The dispersed gas phase sees the boundary as an outlet. The outlet pressure is not specified. Instead, Ansys Fluent automatically specifies

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

a mass sink for the dispersed gas phase in the cells adjacent to the degassing outlet. The mass sink is calculated using the flux normal to the boundary at the cell center.

Note:

The degassing boundary condition is only available for two-phase liquid-gas flows using the Eulerian multiphase model.

7.4.14.1. Limitations

The following limitations apply to the degassing boundary condition in Ansys Fluent:

- The degassing boundary condition is only available for liquid-gas two-phase flow using the Eulerian model. The primary phase must be liquid.
- In order for the gas to escape from the degassing boundary, gravity must be switched on in the model.
- The degassing boundary condition is only recommended for modeling situations like bubble columns without the freeboard region.
- When postprocessing on a degassing boundary, there is no normal velocity for either phase since the gas escape is modeled by a mass sink in the neighboring cells.

7.4.14.2. Inputs at Degassing Boundaries

No inputs are necessary for the degassing boundary condition. However, the initial condition for volume fraction must be set appropriately. It is recommended that the gas phase volume fraction be initialized with a nonzero value smaller than the steady-state gas holdup value.

7.4.15. Wall Boundary Conditions

Wall boundary conditions are used to bound fluid and solid regions. In viscous flows, the no-slip boundary condition is enforced at walls by default, but you can specify a tangential velocity component in terms of the translational or rotational motion of the wall boundary, or model a "slip" wall by specifying shear. (You can also model a slip wall with zero shear using the symmetry boundary type, but using a symmetry boundary will apply symmetry conditions for *all* equations. See Symmetry Boundary Conditions (p. 1474) for details.)

The shear stress and heat transfer between the fluid and wall are computed based on the flow details in the local flow field.

The following topics are discussed in this section:

7.4.15.1. Inputs at Wall Boundaries
7.4.15.2. Stationary Wall
7.4.15.3. Wall Roughness Effects in Turbulent Wall-Bounded Flows
7.4.15.4. Wall Motion
7.4.15.5. Thermal Boundary Conditions at Walls
7.4.15.6. Species Boundary Conditions for Walls

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.15.7. Radiation Boundary Conditions for Walls
7.4.15.8. Discrete Phase Model (DPM) Boundary Conditions for Walls
7.4.15.9. User-Defined Scalar (UDS) Boundary Conditions for Walls
7.4.15.10. Wall Film Conditions for Walls
7.4.15.11. Structural Model Conditions for Walls
7.4.15.12. Default Settings at Wall Boundaries
7.4.15.13. Shear-Stress Calculation Procedure at Wall Boundaries
7.4.15.14. Heat Transfer Calculations at Wall Boundaries

7.4.15.1. Inputs at Wall Boundaries

7.4.15.1.1. Summary

You will enter the following information for a wall boundary:

- wall roughness (for turbulent flows, optional)
- wall motion conditions (for moving or rotating walls)
- shear conditions (for slip walls, optional)
- thermal boundary conditions (for heat transfer calculations)
- species boundary conditions (for species calculations)
- chemical reaction boundary conditions (for surface reactions)
- radiation boundary conditions (for calculations using the P-1, DTRM, DO, surface-to-surface, or MC models)
- discrete phase boundary conditions (for discrete phase calculations)
- wall adhesion contact angle (for VOF calculations, optional)
- displacement boundary conditions for intrinsic fluid-structure interaction (FSI) simulations

7.4.15.2. Stationary Wall

For a stationary wall, choose the **Stationary Wall** option under **Wall Motion**.

7.4.15.3. Wall Roughness Effects in Turbulent Wall-Bounded Flows

Fluids flows over rough surfaces are encountered in diverse situations. Examples are, among many others, flows over the surfaces of airplanes (especially due to ice accretion), ships, turbomachinery, heat exchangers, piping systems, and atmospheric boundary layers over terrain of varying roughness. Wall roughness affects drag (resistance) as well as heat and mass transfer on the walls.

If you are modeling turbulent wall-bounded flow in which the wall roughness effects are considered to be significant, you can include the wall roughness effects through the Standard Law-of-the-Wall Modified for Roughness (for details, see Wall Roughness Effects in Turbulent Wall-Bounded Flows

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

in the *Fluent Theory Guide*) or you can use one of the Additional Roughness Models for Icing Simulations (p. 1438) (for Spalart-Allmaras or the SST k-ω models only).

Note:

Rough walls cannot be used together with the following model combinations:

- An -equation model with enhanced wall treatment or the Menter-Lechner near-wall treatment.

  Note that the following are the relevant -equations:

  – all of the k- models (that is, standard, RNG, and realizable).

  – the Reynolds stress model with Linear Pressure-Strain model selected.

  – the detached eddy simulation (DES) with the Realizable k-epsilon option selected.

- the Reynolds stress model with the Stress-Omega or Stress-BSL model selected.
- the transition k-kl-ω model.
- the Large Eddy Simulation (LES) model with Kader Blending Wall Functions and Werner Wengle Wall Treatment.

7.4.15.3.1. Setting the Roughness Parameters

The roughness parameters are in the **Momentum** tab of the Wall Dialog Box (p. 5031) (see Figure 7.54: The Wall Dialog Box for Marangoni Stress (p. 1445)), which is opened from the Boundary Conditions Task Page (p. 4937) (as described in Setting Cell Zone and Boundary Conditions (p. 1281)).

To model the wall roughness effects, you must specify two roughness parameters: the **Roughness Height**, K_s, and the **Roughness Constant**, C_s. The default roughness height (K_s) is zero, which corresponds to smooth walls. For the roughness to take effect, you must specify a nonzero value for K_s. For a uniform sand-grain roughness, the height of the sand-grain can simply be taken for K_s. For a non-uniform sand-grain, however, the mean diameter (D_{50}) would be a more meaningful roughness height. For other types of roughness, an "equivalent" sand-grain roughness height could be used for K_s. The above approaches are only relevant if the height is considered constant per surface. However, if the roughness constant or roughness height is not constant, then you can specify a profile (see Profiles (p. 1540)). Similarly, user-defined functions may be used to define a wall roughness height that is not constant. For details on the format of user-defined functions, refer to the Fluent Customization Manual.

Choosing a proper roughness constant (C_s) is dictated mainly by the type of the given roughness. The default roughness constant (C_s=0.5) was determined so that, when used with k - ε turbulence models, it reproduces Nikuradse's resistance data for pipes roughened with tightly-packed, uniform sand-grain roughness. You may need to adjust the roughness constant when the roughness you want to model departs much from uniform sand-grain. For instance, there is some experimental evidence that, for non-uniform sand-grains, ribs, and wire-mesh roughness, a higher value (C_s=$0.5\sim1.0$) is more appropriate. Unfortunately, a clear guideline for choosing C_s for arbitrary types of roughness is not available.

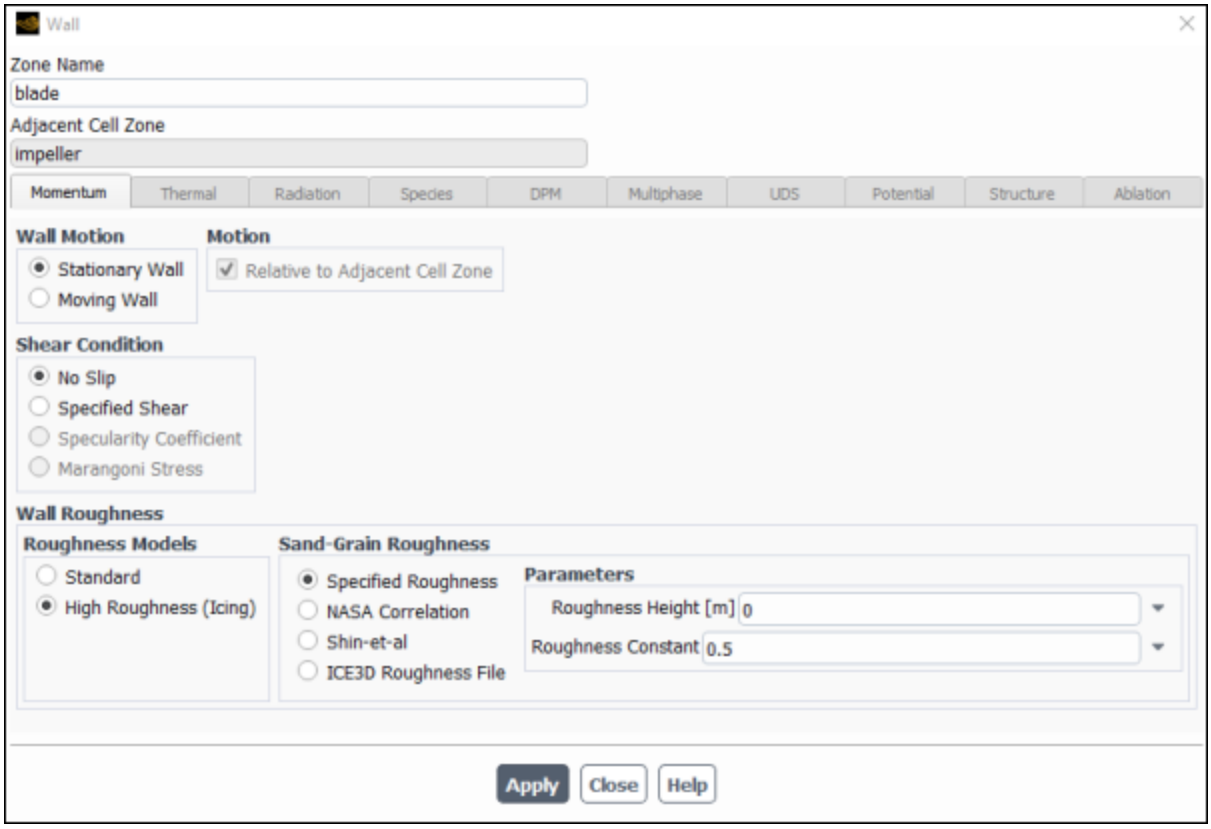
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.15.3.2. Additional Roughness Models for Icing Simulations

Additional roughness models are available if you have selected the **Spalart-Allmaras** or the **SST** k-ω model in the **Viscous Model** dialog box. See the Steps in Using a Turbulence Model (p. 2045) for more information. With one of these viscous models active, the additional roughness models will be available on the **Wall** boundary condition panel on the **Momentum** tab under **Wall Roughness** → **Roughness Models** → **High Roughness (Icing)**. A discussion of the treatment of the turbulence models with the **High Roughness (Icing)** enabled is given in Treatment of the Spalart-Allmaras Model for Icing Simulations and Treatment of the SST Model for Icing Simulations. These models are primarily designed and tested for simulations of icing applications, however they may also be useful for other applications in which the boundary layer is fully resolved and there is surface roughness that is large relative to the near-wall mesh.

Note that the **High Roughness (Icing)** models are only valid for low-Re number turbulence, or need fine near-wall meshes (mesh should fully resolve the boundary layer).

Figure 7.50: The Wall Dialog Box for High Roughness (Icing) Models



You have the following options:

- Specified Roughness
- NASA Correlation
- Shin-et-al
- ICE3D Roughness File

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.15.3.2.1. Specified Roughness

A **Specified Roughness** can be applied in the same manner as described in the section on the **Standard Roughness** model. See Setting the Roughness Parameters (p. 1437) for more details.

7.4.15.3.2.2. NASA Correlation

If the **NASA Correlation** option is selected, the surface sand-grain roughness height is computed with an empirical NASA correlation for icing in air flows [136] (p. 5662). The sand-grain roughness height is computed from the product of the following coefficients:

$$\left[\frac{h_s/c}{\left(h_s/c\right)_{base}}\right]_{V_\infty} = 0.4286 + 0.0044139 V_\infty \tag{7.114}$$

$$\left[\frac{h_s/c}{\left(h_s/c\right)_{base}}\right]_{LC} = 0.5714 + 0.2457\,(LC) + 1.2571\,(LC)^2 \tag{7.115}$$

$$\left[\frac{h_s/c}{\left(h_s/c\right)_{base}}\right]_{T_s} = 0.04\,T_s - 11.27 \tag{7.116}$$

Where V_∞ is the **Free Stream Velocity**, T_s is the **Free Stream Temperature**, LC is the **Liquid Content** (in most cases water for ice accretion), c is the **Characteristic Length**, and $\left(h_s/c\right)_{base} = 0.001177$.

The sand-grain roughness height is then obtained from the formulation:

$$h_s = \left[\frac{h_s/c}{\left(h_s/c\right)_{base}}\right]_{T_s}\left[\frac{h_s/c}{\left(h_s/c\right)_{base}}\right]_{LC}\left[\frac{h_s/c}{\left(h_s/c\right)_{base}}\right]_{V_\infty} \cdot \left(h_s/c\right)_{base} \cdot c \tag{7.117}$$

7.4.15.3.2.3. Shin-et-al

If the **Shin-et-al** option is selected the empirical correlation for the surface sand-grain roughness is computed with the Shin and Bond formulation [136] (p. 5662), which modifies the NASA correlation (see the NASA Correlation (p. 1439) for a description of variables) with the following factor:

$$\left[\frac{h_s/c}{\left(h_s/c\right)_{base}}\right]_{MVD} = \begin{cases} 1 & MVD \le 20 \\ 1.667 - 0.0333(MVD) & MVD > 20 \end{cases} \tag{7.118}$$

where MVD is the droplet mean diameter (**Droplet Diameter**). The corresponding value of the sand-grain roughness height is obtained from:

$$h_s = 0.6839\left[\frac{h_s/c}{\left(h_s/c\right)_{base}}\right]_{LC}\left[\frac{h_s/c}{\left(h_s/c\right)_{base}}\right]_{T_s}\left[\frac{h_s/c}{\left(h_s/c\right)_{base}}\right]_{MVD} \cdot \left(h_s/c\right)_{base} \cdot c \tag{7.119}$$

7.4.15.3.2.4. ICE3D Roughness File

If the **ICE3D Roughness File** is selected, the sand-grain roughness height is read from a node-based input file obtained from FENSAP-ICE. The file must have the format $\left\{x_i, y_i, z_i, h_{s,i}\right\}$, and

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

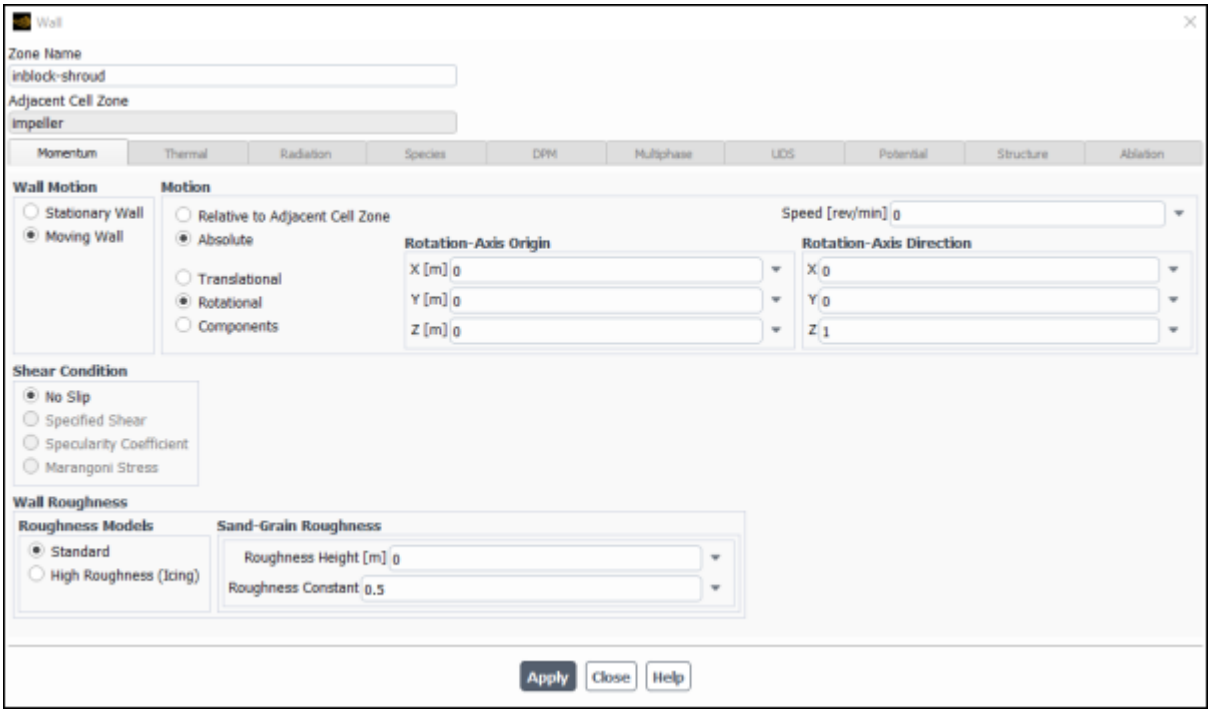
be read in Fluent via **File** → **Read** → **Profile**. After the FENSAP-ICE roughness file is read into Fluent, the file name will appear in the dropdown list.

7.4.15.4. Wall Motion

Wall boundaries can be either stationary or moving. The stationary boundary condition specifies a fixed wall, whereas the moving boundary condition can be used to specify the translational or rotational velocity of the wall, or the velocity components.

Wall motion conditions are entered in the **Momentum** tab of the Wall Dialog Box (p. 5031) (Figure 7.51: The Wall Dialog Box for a Moving Wall (p. 1440)), which is opened from the Boundary Conditions Task Page (p. 4937) (as described in Setting Cell Zone and Boundary Conditions (p. 1281)). To view the wall motion conditions, click the **Momentum** tab.

Figure 7.51: The Wall Dialog Box for a Moving Wall



7.4.15.4.1. Velocity Conditions for Moving Walls

If you want to include tangential motion of the wall in your calculation, you need to define the translational or rotational velocity, or the velocity components. Select the **Moving Wall** option under **Wall Motion**. The **Wall** dialog box will expand, as shown in Figure 7.51: The Wall Dialog Box for a Moving Wall (p. 1440), to show the wall velocity conditions.

Note that you cannot use the moving wall condition to model problems where the wall motion with respect to the adjacent cell zone has a component that is normal to the wall itself. For such problems, consider using a Sliding or Dynamic Mesh approach as discussed in Modeling Flows Using Sliding and Dynamic Meshes (p. 1765). Ansys Fluent will neglect any normal component of wall motion that you specify using the methods below.

- **Specifying Relative or Absolute Velocity**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If the cell zone adjacent to the wall is moving (for example, if you are using a moving reference frame or a sliding mesh), you can choose to specify velocities relative to the zone motion by enabling the **Relative to Adjacent Cell Zone** option. If you choose to specify relative velocities, a velocity of zero means that the wall is stationary in the relative frame, and therefore moving at the speed of the adjacent cell zone in the absolute frame. If you choose to specify absolute velocities (by enabling the **Absolute** option), a velocity of zero means that the wall is stationary in the absolute frame, and therefore moving at the speed of the adjacent cell zone—but in the opposite direction—in the relative reference frame.

Important:

If you are using one or more moving reference frames, sliding meshes, or mixing planes, and you want the wall to be fixed in the moving frame, it is recommended that you specify relative velocities (the default) rather than absolute velocities. Then, if you modify the speed of the adjacent cell zone, you will not need to make any changes to the wall velocities, as you would if you specified absolute velocities.

Note that if the adjacent cell zone is not moving, the absolute and relative options are equivalent.

- **Translational Wall Motion**

  For problems that include linear translational motion of the wall boundary (for example, a rectangular duct with a moving belt as one wall) you can enable the **Translational** option and specify the wall's **Speed** and **Direction** (**X,Y,Z** vector). By default, wall motion is "disabled" by the specification of **Translational** velocity with a **Speed** of zero. You can define time-varying translational speed using a transient profile (Standard Transient Profiles (p. 1500)) or user-defined function for the speed of the wall.

  If you need to define nonlinear translational motion, you will need to use the **Components** option, described below.

- **Rotational Wall Motion**

  For problems that include rotational wall motion you can enable the **Rotational** option and define the rotational **Speed** about a specified axis. To define the axis, set the **Rotation-Axis Direction** and **Rotation-Axis Origin**. This axis is independent of the axis of rotation used by the adjacent cell zone, and independent of any other wall rotation axis. For 3D problems, the axis of rotation is the vector passing through the specified **Rotation-Axis Origin** and parallel to the vector from (0,0,0) to the (**X,Y,Z**) point specified under **Rotation-Axis Direction**. For 2D problems, you will specify only the **Rotation-Axis Origin**; the axis of rotation is the z -direction vector passing through the specified point. For 2D axisymmetric problems, you will not define the axis: the rotation will always be about the x axis, with the origin at (0,0). You can define time-varying rotational speed using a transient profile (Standard Transient Profiles (p. 1500)) profile or a user-defined function for the speed of the wall.

  Note that the modeling of tangential rotational motion will be correct only if the wall bounds a surface of revolution about the prescribed axis of rotation (for example, a circle or cylinder). Note also that rotational motion can be specified for a wall in a stationary reference frame.

- **Wall Motion Based on Velocity Components**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For problems that include linear or nonlinear translational motion of the wall boundary you can enable the **Components** option and specify the **X-Velocity**, **Y-Velocity**, and **Z-Velocity** of the wall. You can define nonlinear translational motion using a profile or a user-defined function for the **X-Velocity**, **Y-Velocity**, and/or **Z-Velocity** of the wall.

- **Wall Motion for Two-Sided Walls**

  As discussed earlier in this section, when you read a mesh with a two-sided wall zone (which forms the interface between fluid/solid regions) into Ansys Fluent, a "shadow" zone will automatically be created so that each side of the wall is a distinct wall zone. For two-sided walls, it is possible to specify different motions for the wall and shadow zones, whether or not they are coupled. Note, however, that you cannot specify motion for a wall (or shadow) that is adjacent to a solid zone.

7.4.15.4.2. Shear Conditions at Walls

Four types of shear conditions are available:

- no-slip
- specified shear
- specularity coefficient
- Marangoni stress

The no-slip condition is the default, and it indicates that the fluid sticks to the wall and moves with the same velocity as the wall, if it is moving. The specified shear and Marangoni stress boundary conditions are useful in modeling situations in which the shear stress (rather than the motion of the fluid) is known. Examples of such situations are applied shear stress, slip wall (zero shear stress), and free surface conditions (zero shear stress or shear stress dependent on surface tension gradient). The specified shear boundary condition allows you to specify the x, y, and z components of the shear stress as constant values or profiles. The Marangoni stress boundary condition allows you to specify the gradient of the surface tension with respect to the temperature at this surface. The shear stress is calculated based on the surface gradient of the temperature and the specified surface tension gradient. The Marangoni stress option is available only for calculations in which the energy equation is being solved.

The specularity coefficient shear condition is specifically used in multiphase with granular flows. The specularity coefficient is a measure of the fraction of collisions that transfer momentum to the wall and its value ranges between zero and unity. This implementation is based on the Johnson and Jackson [71] (p. 5659) boundary conditions for granular flows.

Shear conditions are entered in the **Momentum** tab of the Wall Dialog Box (p. 5031), which is opened from the Boundary Conditions Task Page (p. 4937) (as described in Setting Cell Zone and Boundary Conditions (p. 1281)).

7.4.15.4.3. No-Slip Walls

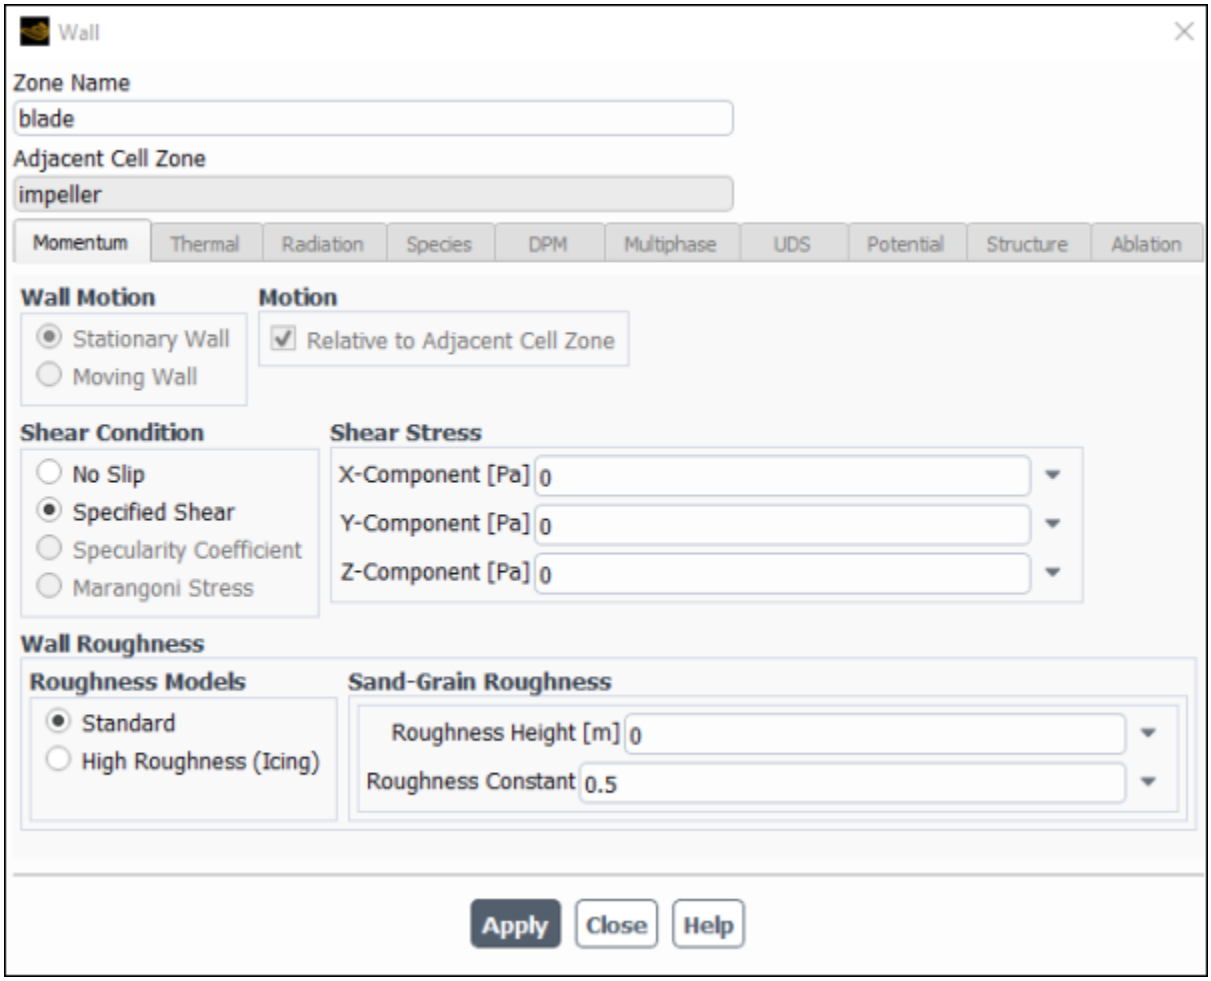
You can model a no-slip wall by selecting the **No Slip** option under **Shear Condition**. This is the default for all walls in viscous flows.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.15.4.4. Specified Shear

In addition to the no-slip wall that is the default for viscous flows, you can model a slip wall by specifying zero or nonzero shear. For nonzero shear, the shear to be specified is the shear at the wall by the fluid. To specify the shear, select the **Specified Shear** option under **Shear Condition** (see Figure 7.52: The Wall Dialog Box for Specified Shear (p. 1443)). You can then enter x, y, and z components of shear under **Shear Stress**.

Figure 7.52: The Wall Dialog Box for Specified Shear



7.4.15.4.5. Specularity Coefficient

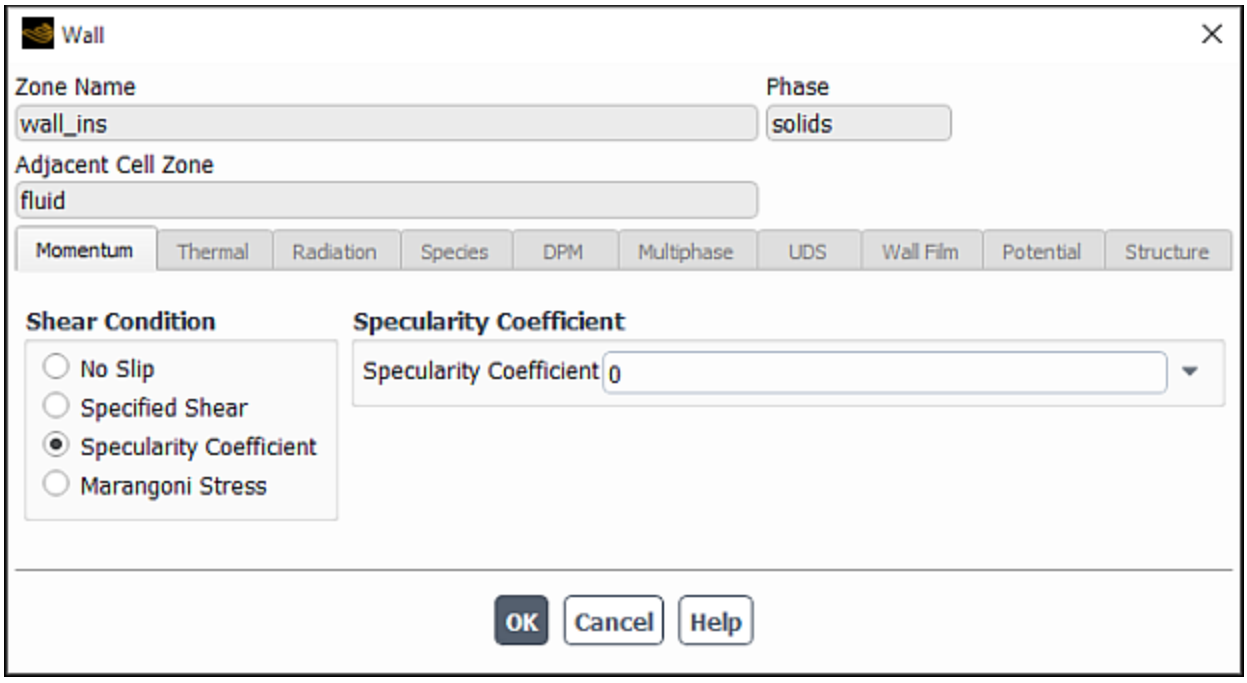
For multiphase granular flow, you can specify the specularity coefficient such that when the value is zero, this condition is equivalent to zero shear at the wall, but when the value is near unity, there is a significant amount of lateral momentum transfer. To specify the specularity coefficient, select the **Specularity Coefficient** option under **Shear Condition** (see Figure 7.53: The Wall Dialog Box for the Specularity Coefficient (p. 1444)) and enter the desired value in the text-entry box under **Specularity Coefficient**.

Note:

The specularity coefficient is not available for moving walls.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.53: The Wall Dialog Box for the Specularity Coefficient



7.4.15.4.6. Marangoni Stress

Ansys Fluent can also model shear stresses caused by the variation of surface tension due to temperature. The shear stress applied at the wall is given by

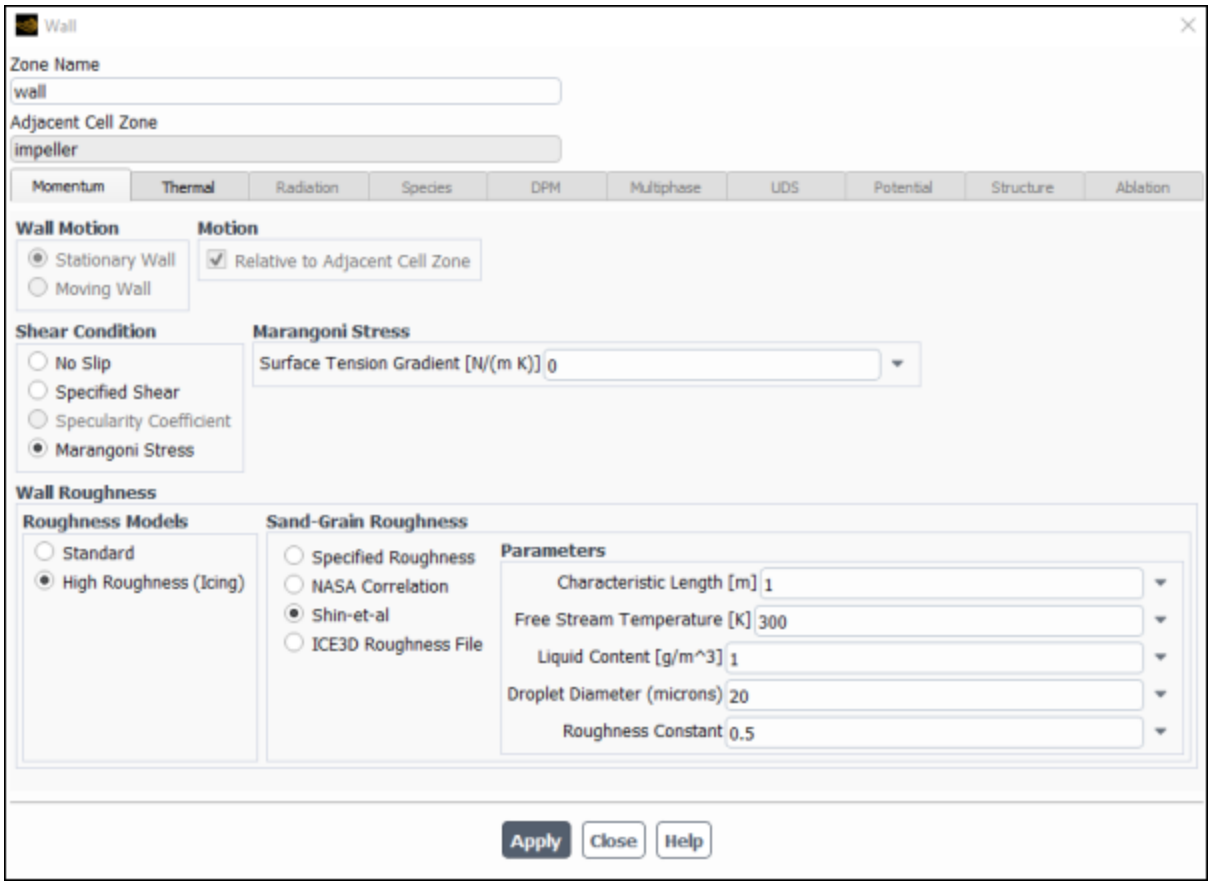
$$\tau = \frac{d\sigma}{dT} \nabla_s T \tag{7.120}$$

where $d\sigma / dT$ is the surface tension gradient with respect to temperature, and $\nabla_s T$ is the surface gradient. This shear stress is then applied to the momentum equation.

To model Marangoni stress for the wall, select the **Marangoni Stress** option under **Shear Condition** (see Figure 7.54: The Wall Dialog Box for Marangoni Stress (p. 1445)). This option is available only for calculations in which the energy equation is being solved. You can then enter the surface tension gradient ($d\sigma / dT$ in Equation 7.120 (p. 1444)) in the **Surface Tension Gradient** field. Wall functions for turbulence are not used with the **Marangoni Stress** option.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.54: The Wall Dialog Box for Marangoni Stress



7.4.15.4.7. Partial Slip for Rarefied Gases

Ansys Fluent offers a partial-slip boundary condition for rarefied gases. In the rarefied regime, the finite amount of friction is no longer sufficient to allow the full adhesion of gas particles onto solid walls, see Partial Slip for Rarefied Gases (p. 2314).

7.4.15.5. Thermal Boundary Conditions at Walls

When you are solving the energy equation, you need to define thermal boundary conditions at wall boundaries. Seven types of thermal conditions are available:

- fixed heat flux
- fixed temperature
- convective heat transfer
- external radiation heat transfer
- combined external radiation and convection heat transfer
- thermal data transferred between another system in Workbench using System Coupling
- thermal coupling across a mapped interface

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

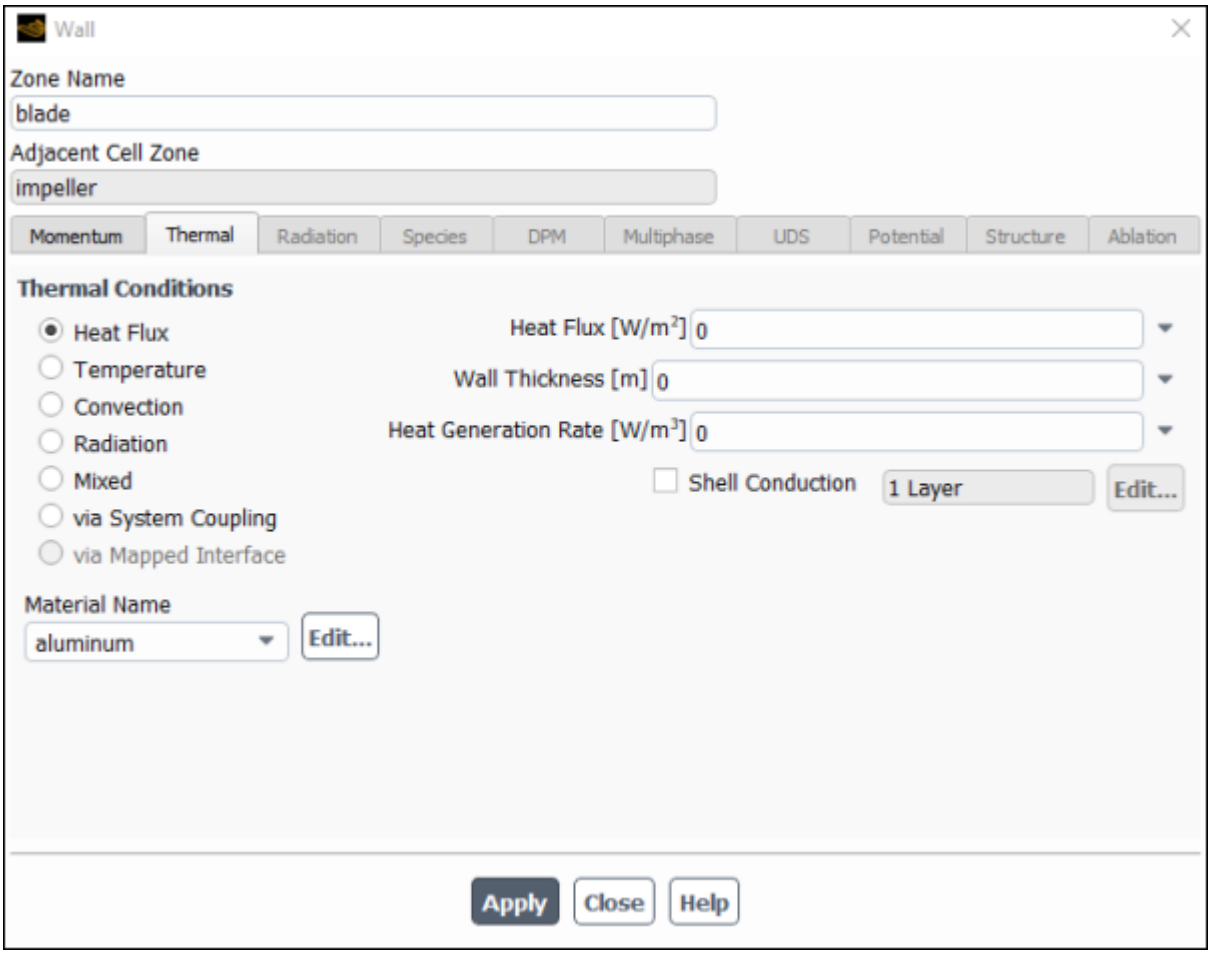
If the wall zone is a "two-sided wall" (a wall that forms the interface between two regions, such as the fluid/solid interface for a conjugate heat transfer problem) a subset of these thermal conditions will be available, but you will also be able to choose whether or not the two sides of the wall are "coupled". See below for details.

The inputs for each type of thermal condition are described below. If the wall has a nonzero-thickness, you should also set parameters for calculating thin-wall thermal resistance and heat generation in the wall, as described below.

You can model conduction within boundary walls and internal (that is, two-sided) walls of your model. This type of conduction, called shell conduction, allows you to more conveniently model heat conduction on walls where the wall thickness is small with respect to the overall geometry (for example, finned heat exchangers or sheet metal in automobile underhoods). Meshing these walls with solid cells would lead to high-aspect-ratio meshes and a significant increase in the total number of cells. See below for details about shell conduction.

Thermal conditions are entered in the **Thermal** tab of the Wall Dialog Box (p. 5031) (Figure 7.55: The Wall Dialog Box (Thermal Tab) (p. 1446)), which is opened from the **Boundary Conditions** task page (as described in Setting Cell Zone and Boundary Conditions (p. 1281)).

Figure 7.55: The Wall Dialog Box (Thermal Tab)



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.15.5.1. Heat Flux Boundary Conditions

For a fixed heat flux condition, choose the **Heat Flux** option under **Thermal Conditions**. You will then need to set the appropriate value for the heat flux at the wall surface in the **Heat Flux** field. You can define an adiabatic wall by setting a zero heat flux condition. This is the default condition for all walls.

7.4.15.5.2. Temperature Boundary Conditions

To select the fixed temperature condition, choose the **Temperature** option under **Thermal Conditions** in the **Wall** dialog box. You will need to specify the temperature at the wall surface (**Temperature**). The heat transfer to the wall is computed using Equation 7.123 (p. 1458) or Equation 7.124 (p. 1458).

7.4.15.5.3. Convective Heat Transfer Boundary Conditions

For a convective heat transfer wall boundary, select **Convection** under **Thermal Conditions**. Your inputs of **Heat Transfer Coefficient** and **Free Stream Temperature** will allow Ansys Fluent to compute the heat transfer to the wall using Equation 7.127 (p. 1459).

7.4.15.5.4. External Radiation Boundary Conditions

If radiation heat transfer from the exterior of your model is of interest, you can enable the **Radiation** option in the **Wall** dialog box and set the **External Emissivity** and **External Radiation Temperature**.

7.4.15.5.5. Combined Convection and External Radiation Boundary Conditions

You can choose a thermal condition that combines the convection and radiation boundary conditions by selecting the **Mixed** option. With this thermal condition, you will need to set the **Heat Transfer Coefficient**, **Free Stream Temperature**, **External Emissivity**, and **External Radiation Temperature**.

7.4.15.5.6. Augmented Heat Transfer

When modeling the heat transfer of applications that have perturbed flow and/or disturbed boundary layers, it can be necessary to augment the calculation of the diffusive heat flux with a convective augmentation factor. Such applications include the modeling of underhood and underbody heat loads, as wells as transient heat transfer in fully warmed-up exhaust systems.

The convective augmentation factor represents the ratio of the measured Nusselt number to the Nusselt number of an ideal flow. You can define it by using the following text command:

`define` → `boundary-conditions` → `wall`

You will be prompted to define the `Convective Augmentation Factor` as either a profile or a single value. Note that a value of 1 (the default value) represents no augmentation of the diffusive heat flux, whereas values greater than 1 initiate augmentation. For further details, see the equation for `qid` in `DEFINE_HEAT_FLUX` of the Fluent Customization Manual.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.15.5.7. Thin-Wall Thermal Resistance Parameters

By default, a wall will have a thickness of zero. You can, however, in conjunction with any of the thermal conditions, model a thin layer of material on the wall. For example, you can model the effect of a piece of sheet metal between two fluid zones, a coating on a solid zone, or contact resistance between two solid regions. Ansys Fluent will solve a 1D steady heat conduction equation to compute the thermal resistance offered by the wall and the heat generation in the wall.

To include these effects in the heat transfer calculation you will need to specify the type of material, the thickness of the wall, and the heat generation rate in the wall:

1. Select the material type in the **Material Name** drop-down list, and

   If you want to check or modify the properties of the selected material, you can click **Edit...** to open the **Edit Material** dialog box; this dialog box contains just the properties of the selected material, not the full contents of the standard **Create/Edit Materials** dialog box.

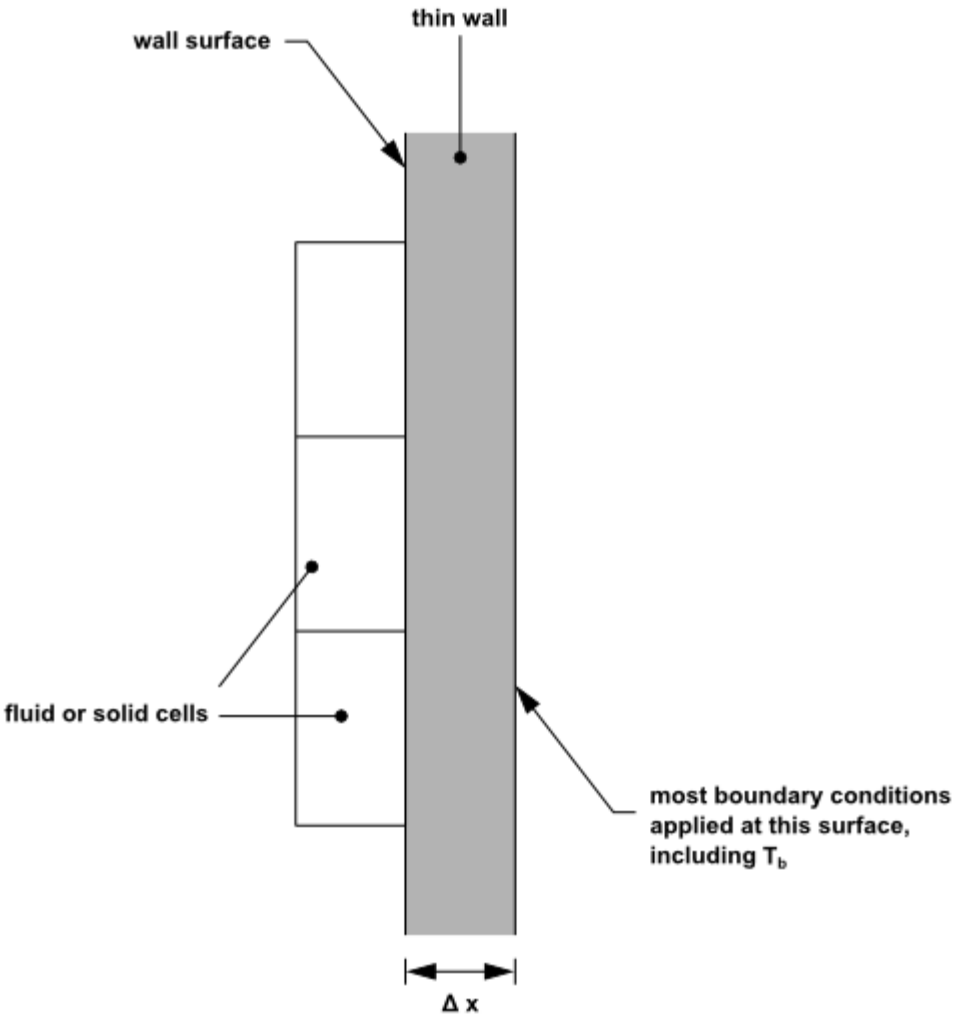
2. Specify the thickness in the **Wall Thickness** field.

   You can specify a constant thickness or you can specify a variable thickness using an expression, UDF, or profile.

   When you specify a thickness, the wall is then treated as a coupled wall, where the surface that is adjacent to the fluid / solid cells is referred to as the "wall surface". See Figure 7.56: A Thin Wall (p. 1449).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.56: A Thin Wall



The thermal resistance of the wall is $\Delta x / k$, where k is the conductivity of the wall material and Δx is the wall thickness. The thermal wall boundary condition you set will be specified on the surface that is separated from the fluid / solid cells by the wall thickness. The temperature specified at this side of the wall is T_b.

Important:

Note that for thin walls, you can only specify a constant thermal conductivity. If you want to use a non-constant thermal conductivity for a wall with nonzero-thickness, you should use the shell conduction model (see Shell Conduction (p. 1452) for details).

3. Specify the heat generation rate inside the wall in the **Heat Generation Rate** field. This option is useful if, for example, you are modeling printed circuit boards where you know the electrical power dissipated in the circuits.

When postprocessing a wall that has a thickness but does not have shell conduction enabled, the **Temperature...** category provides three options: the temperature of the adjacent fluid / solid

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

cells are stored as **Static Temperature**; the temperature of the wall surface itself is stored as **Wall Temperature**; and the temperature of the surface that is separated from the fluid / solid cells by the wall thickness is stored as **Wall Temperature (Thin)**. If a more detailed analysis of the solid zone and surfaces is required, then you should consider creating layers of solid cells in your meshing application.

7.4.15.5.8. Thermal Conditions for Two-Sided Walls

If the wall zone has a fluid or solid region on each side, it is called a "two-sided wall". When you read a mesh with this type of wall zone into Ansys Fluent, a "shadow" zone will automatically be created so that each side of the wall is a distinct wall zone. In the **Wall** dialog box, the shadow zone's name will be shown in the **Shadow Face Zone** field. You can choose to specify different thermal conditions on each zone, or to couple the two zones:

- To couple the two sides of the wall (creating a "coupled wall"), select the **Coupled** option under **Thermal Conditions**. (This option will appear in the **Wall** dialog box only when the wall is a two-sided wall.) No additional thermal boundary conditions are required, because the solver will calculate heat transfer directly from the solution in the adjacent cells. You can, however, specify the material type, wall thickness, and heat generation rate for thin-wall thermal resistance calculations, as described in Thin-Wall Thermal Resistance Parameters (p. 1448). Note that the resistance parameters you set for one side of the wall will automatically be assigned to its shadow wall zone. Specifying the heat generation rate inside the wall is useful if, for example, you are modeling printed circuit boards where you know the electrical power dissipated in the circuits but not the heat flux or wall temperature.

  Note:

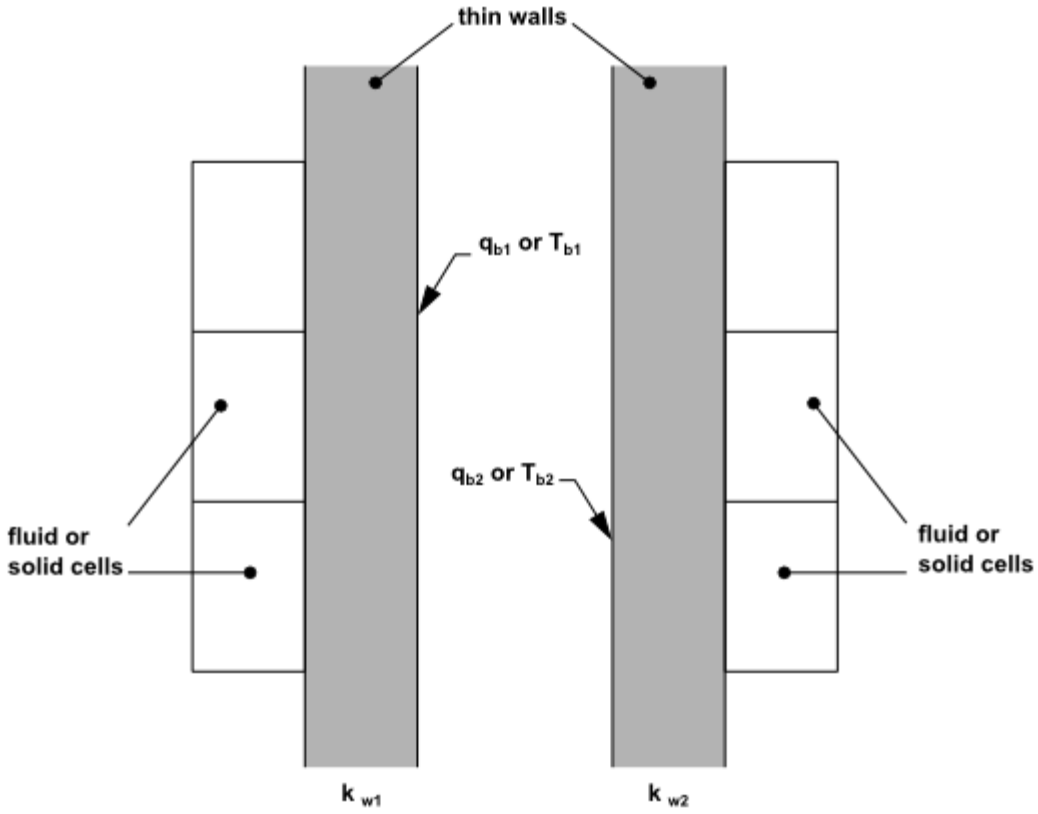
  – For inviscid flows with two-sided walls, the **Thermal** tab is greyed out and the reported heat flux on the CHT surface will be 0.

  – Results may differ for coupled walls that are intersecting boundaries. That is, you may see different results on a wall as compared to its wall-shadow depending on whether **Node Values** are enabled/disabled in this scenario.

- To uncouple the two sides of the wall and specify different thermal conditions on each one, choose **Temperature** or **Heat Flux** as the thermal condition type (**Convection** and **Radiation** are not applicable for two-sided walls); note that this uncoupling will not be effective if you have enabled shell conduction for the wall. The relationship between the wall and its shadow will be retained, so that you can couple them again at a later time, if desired. You will need to set the relevant parameters for the selected thermal condition, as described above. The two uncoupled walls can have different thicknesses, and are effectively insulated from one another. If you specify a nonzero wall thickness for the uncoupled walls, the thermal boundary conditions you set will be specified for each thin wall on the surface that is separated from the fluid / solid cells by the wall thickness, as shown in Figure 7.57: Uncoupled Thin Walls (p. 1451), where T_{b1} is the **Temperature** (or q_{b1} is the **Heat Flux**) specified on one wall and T_{b2} is the **Temperature** (or q_{b2} is the **Heat Flux**) specified on the other wall. k_{w1} and k_{w2} are the thermal conductivities of the uncoupled thin walls. Note that the gap between the walls in Figure 7.57: Uncoupled Thin Walls (p. 1451) is not part of the model; it is included in the figure only to show where the thermal boundary condition for each uncoupled wall is applied.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.57: Uncoupled Thin Walls



7.4.15.5.8.1. Orthogonality-Based Secondary Gradient Limiting at Coupled Two-Sided Walls

When cells near coupled two-sided walls have poor face orthogonality with respect to the wall, the tangential component (also known as the secondary gradient) of the discretized diffusive flux for the energy and user-defined scalar equations can become unbounded. This generates instabilities that can lead to solution divergence. When using the pressure-based solver, you have the option of limiting the secondary gradients in order to control the cross-diffusion source term. This control mechanism can improve the robustness of the discretization method while maintaining solution accuracy.

When this secondary gradient limiting is enabled, the diffusive flux approximation (described in Connectivity Macros in the *Fluent Customization Manual*) at the wall is modified so that a coefficient (ψ) controls the diffusion term:

$$D_f = \Gamma_f \frac{\left(\phi_1 - \phi_0\right)}{ds} \frac{\vec{A}\cdot\vec{A}}{\vec{A}\cdot\vec{e}_s} + \psi\Gamma_f \left(\overline{\nabla}\phi\cdot\vec{A} - \overline{\nabla}\phi\cdot\vec{e}_s \frac{\vec{A}\cdot\vec{A}}{\vec{A}\cdot\vec{e}_s} \right) \tag{7.121}$$

where the diffusion coefficient ψ is a function of face orthogonality—that is, the dot product between $\vec{A}$ (the area vector for the face, normal to the wall) and $\vec{e}_s$ (the unit vector along the line connecting the cell centroid (0) and face centroid (1)). Note that $0 \le \psi \le 1$.

Note the following limitations:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- It is only available with the pressure-based solver.
- It can only be applied to the energy calculation and/or user-defined scalars (UDS) on coupled two-sided walls (that is, wall / wall-shadow pairs with **Coupled** selected from the **Thermal Conditions** list in the **Thermal** tab).

To enable orthogonality-based secondary gradient limiting, use the following text commands:

- For the energy equation:

  `solve → set → advanced → secondary-gradient-limiting → energy?`

- For user-defined scalars:

  `solve → set → advanced → secondary-gradient-limiting → uds?`

When you enable secondary gradient limiting, by default it is applied to faces on the coupled two-sided walls using mesh quality limits from 0.7–0.9. You can shift the range if necessary by using the following text command; note that shifting this range closer to 1 will decrease the risk of divergence, but at the cost of accuracy.

`solve → set → advanced → secondary-gradient-limiting → mesh-quality-limits`

7.4.15.5.9. Shell Conduction

To enable shell conduction for a wall, enable the **Shell Conduction** option in the **Wall** boundary condition dialog box. You can then click the **Edit...** button to open the **Shell Conduction Layers** dialog box, where you can define the properties of the single or multiple layers of the shell. Note that you must specify a nonzero wall thickness for every layer of the shell. When shell conduction is enabled, Ansys Fluent will compute heat conduction for the wall not only in the normal direction (which is always computed when the energy equation is solved), but also in the planar directions. The **Shell Conduction** option will appear in the **Wall** dialog box for all walls when solution of the energy equation is active (except for mapped interfaces). For information about how the thermal conditions are applied on a wall with shell conduction enabled, managing multiple shells, and postprocessing shell conduction walls, see Shell Conduction (p. 2146).

Ansys Fluent cases with shell conduction can be read in serial or parallel. Either a partitioned or an unpartitioned case file can be read in parallel (see Mesh Partitioning and Load Balancing (p. 4281) for more information on partitioning). After reading a case file in parallel, shell zones can be created on any wall.

To convert every wall with a finite thickness into a shell with a single action, the TUI command `define/boundary-conditions/modify-zones/create-all-shell-threads` can be used; each converted shell will have a single layer with the same thickness as the original thin wall (any pre-existing shells will not be modified). To disable shell conduction in every wall with a single action, the TUI command `define/boundary-conditions/modify-zones/delete-all-shells` can be used. These capabilities are available in both serial and parallel mode.

For more information on shell conduction, see Shell Conduction (p. 2146).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.15.5.10. Heat Transfer Boundary Conditions Through System Coupling

System Coupling allows the input and output of thermal data from Ansys Fluent. When Fluent is coupled with another system in Workbench using System Coupling, you can select the **via System Coupling** option on the desired wall boundaries to receive thermal data through System Coupling service. Note that this option does not need to be selected to provide thermal data from Fluent.

For more details about setting up a simulation with System Coupling, see the Performing System Coupling Simulations Using Fluent (p. 4595) and the System Coupling User's Guide.

When thermal data is transferred into Fluent via System Coupling, the following variables are available:

- temperature
- heat flow (heat rate)
- heat transfer coefficient (also known as "convection coefficient")

When thermal data is transferred out of Fluent via System Coupling, the following variables are available:

- temperature
- heat flow (heat rate)
- heat transfer coefficient (also known as "convection coefficient")
- near wall temperature (also known as "bulk temperature" or "ambient temperature")

For each data transfer, you specify the type of data transfer (the variables transferred) during the System Coupling setup.

As part of standard heat transfer boundary condition settings in Ansys Fluent, you can also specify the type of material, the thickness of the wall, and the heat generation rate in the wall. Select the material type in the **Material Name** drop-down list; if you want to check or modify the properties of the selected material, you can click **Edit...** to open the **Edit Material** dialog box (this dialog box contains just the properties of the selected material, and not the full contents of the standard **Create/Edit Materials** dialog box). You can specify the thickness in the **Wall Thickness** number-entry box and the heat generation rate in the **Heat Generation Rate** number-entry box.

Note:

A boundary will behave in the same way as an adiabatic boundary if the **via System Coupling** option is enabled on this boundary, and Ansys Fluent is not receiving data from the coupling data transfer. Fluent is not receiving coupling data if it is either not involved with a System Coupling simulation, or if the coupling is a one-way transfer with the Fluent analysis only providing data to the second solver.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.15.5.11. Heat Transfer Boundary Conditions Across a Mapped Interface

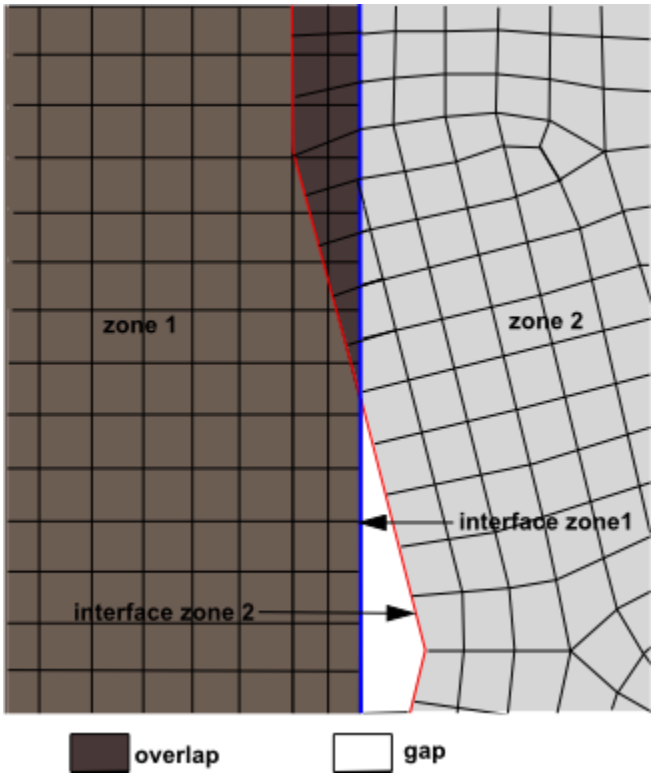
Mapped interfaces provide a robust approach for modeling coupled walls between zones when the interface zones penetrate each other or have gaps between them (see Figure 7.58: 2D Interface with Penetration and Gaps (p. 1454)). For the interface wall boundary zones created as part of such interfaces, **via Mapped Interface** is automatically selected from the **Thermal Conditions** list in the **Thermal** tab of the **Wall** dialog box, in order to interpolate the thermal data.

Important:

Note that thermal coupling calculations will not be performed at mapped interfaces for the Eulerian multiphase model.

For more details about mapped interfaces, see The Mapped Option (p. 1157) and Using a Non-Conformal Mesh in Ansys Fluent (p. 1164).

Figure 7.58: 2D Interface with Penetration and Gaps



Such boundaries also allow you to specify the standard heat transfer boundary condition settings, such as the type of material, the thickness of the wall, and the heat generation rate in the wall. Select the material type in the **Material Name** drop-down list; if you want to check or modify the properties of the selected material, you can click **Edit...** to open the **Edit Material** dialog box (this dialog box contains just the properties of the selected material, and not the full contents of the standard **Create/Edit Materials** dialog box). You can specify the thickness in the **Wall Thickness** number-entry box and the heat generation rate in the **Heat Generation Rate** number-entry box. Note that the **Shell Conduction** option is not available with the **via Mapped Interface** thermal condition.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.15.5.12. Temperature Jump for Rarefied Gases

In the rarefied regime, the parietal gas temperature may differ from the imposed wall temperature. For details, see Temperature Jump for Rarefied Gases (p. 2316).

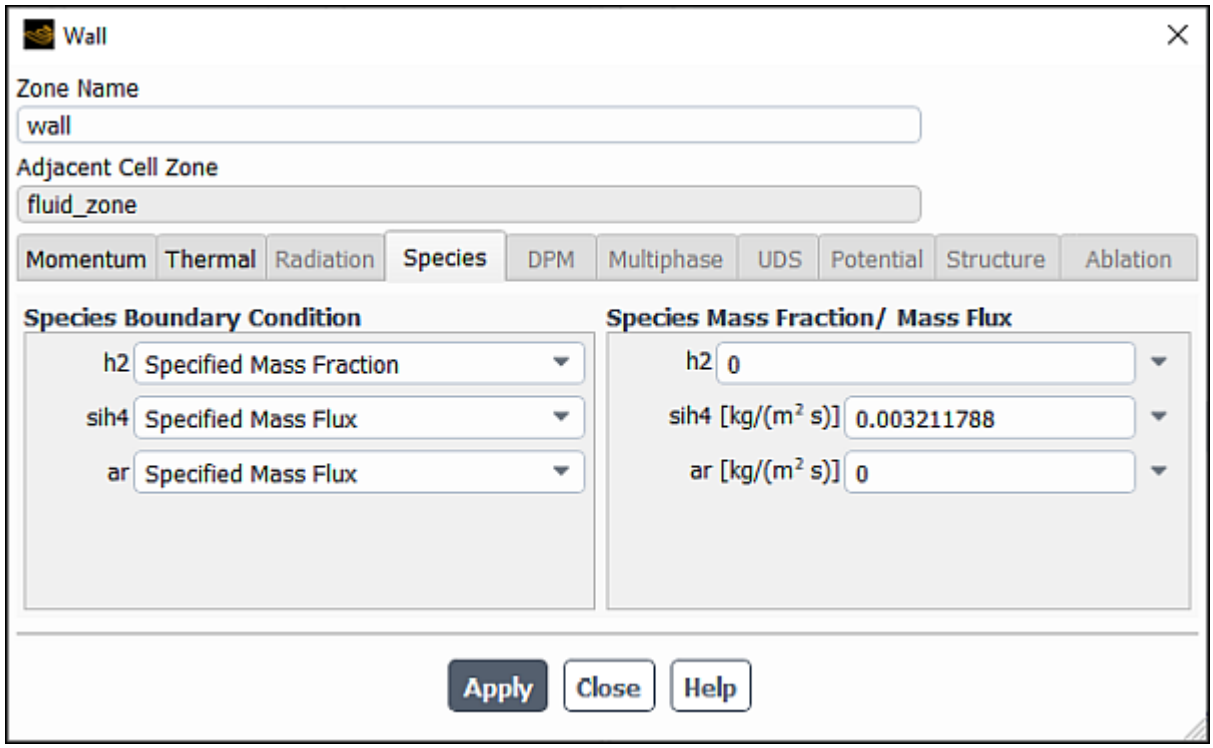
7.4.15.6. Species Boundary Conditions for Walls

By default, a zero mass flux condition for all species is assumed at walls (except for species that participate in surface reactions). You can change the default settings and specify species mass fractions or non-zero mass fluxes at walls in your simulation. That is, both Dirichlet and Neumann boundary conditions such as those that are specified at inlets can be used at walls as well.

To change the default zero mass flux boundary condition for a species at the wall:

1. In the Wall Dialog Box (p. 5031), go to the **Species** tab to view the species boundary conditions for the wall (see Figure 7.59: The Wall Dialog Box for Species Boundary Condition Input (p. 1455)).

   Figure 7.59: The Wall Dialog Box for Species Boundary Condition Input



2. In the **Species Boundary Condition** group box, you can define one of the following boundary conditions for the species at the wall:

   - If you want to specify a non-zero species mass flux, select **Specified Mass Flux** (default) in the drop-down list to the right of the species name. Then in the **Species Mass Fraction / Mass Flux** group box, enter its value for the species of interest.

   - Similarly, if you want to specify a species mass fraction, select **Specified Mass Fraction** in the drop-down list to the right of the species name. Then in the **Species Mass Fraction / Mass Flux** group box, enter its value for the species of interest.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The boundary condition type for each species is specified separately, so you can choose to use different methods for different species.

If you are modeling species transport with **Wall Surface** reactions enabled in the **Species Model** dialog box, you can alternatively enable a reaction mechanism at a wall by selecting the **Reaction** option and then selecting an available mechanism from the **Reaction Mechanisms** drop-down list. See Defining Zone-Based Reaction Mechanisms (p. 2385) for more information about defining reaction mechanisms.

You can also model unresolved surface washcoats, which greatly increase the catalytic surface area, by specifying the **Surface Area Washcoat Factor**. The surface washcoat increases the area available for surface reaction.

In transient simulations, if you want to postprocess the deposition of the solid species on the wall over time, you need to specify the following parameters:

- **Initial Deposition Thickness**: is the thickness of the solid species deposition on the wall at the start of the simulation.
- **Solid Species Density**: is the density of the solid species deposited on the wall. If more than one solid species exist in your simulation, then you need to specify the average solid species density.

Note that these two parameters are used for postprocessing purposes only and will not affect simulation results.

7.4.15.6.1. Partial Catalytic Boundary Conditions for Walls

In hypersonic flows, the recombination of atoms is usually dominant at the wall. The atoms that diffuse to the wall can either reflect from the wall or recombine into molecules, see Partial Catalytic Boundary Condition for Walls (p. 2317).

7.4.15.7. Radiation Boundary Conditions for Walls

If you are using the gray P-1, DTRM, DO, surface-to-surface, or MC models, you will need to set the emissivity of the wall (**Internal Emissivity**) in the **Thermal** tab of the **Wall** dialog box. If you are using the Rosseland model you do not need to set the emissivity, because Ansys Fluent assumes the emissivity is 1.

For the non-gray P-1, DO, or MC models, specify a constant **Internal Emissivity** for each wavelength band in the **Radiation** tab of the **Wall** dialog box (the default value in each band is 1). Alternatively, you can specify the internal emissivity using a boundary condition parameter (see Creating a New Parameter (p. 1289)). If you are using the non-gray DO or MC models, you will also need to define the wall as opaque or semi-transparent in the **Radiation** tab. See Defining Boundary Conditions for Radiation (p. 2181) for details. If you are using the DO or MC models, you can enable a **Boundary Source**.

7.4.15.8. Discrete Phase Model (DPM) Boundary Conditions for Walls

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the wall in the **DPM** section of the **Wall** dialog box. See Setting Boundary Conditions for the Discrete Phase (p. 2776) for details.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.15.8.1. Wall Adhesion Contact Angle for VOF Model

If you are using the VOF model and you are modeling wall adhesion, you can specify the contact angle for each pair of phases at the wall in the **Momentum** tab of the **Wall** dialog box. See Steps for Setting Boundary Conditions (p. 2953) for details.

7.4.15.9. User-Defined Scalar (UDS) Boundary Conditions for Walls

If you have defined UDS transport equations in your model, you can specify boundary conditions for each equation in the **UDS** section of the **Wall** dialog box. See Setting Up UDS Equations in Ansys Fluent (p. 1711) for details.

7.4.15.10. Wall Film Conditions for Walls

If you are using the Eulerian Wall Film model (see Modeling Eulerian Wall Films (p. 3231) for details), you can set liquid film conditions at the wall in the **Wall Film** tab of the **Wall** dialog box. This tab is available only if you have enabled the Eulerian Wall Film model in the Models Task Page (p. 4644).

For details, see Setting Eulerian Wall Film Solution Controls (p. 3240).

7.4.15.11. Structural Model Conditions for Walls

For an intrinsic fluid-structure interaction (FSI) simulation, you can set the displacement boundary condition settings for walls that are adjacent to solid cell zones in the **Structure** tab of the **Wall** dialog box. This tab is only available when a model is selected in the Structural Model Dialog Box (p. 4817). For details, see Setting Up an Intrinsic Fluid-Structure Interaction (FSI) Simulation (p. 3220).

7.4.15.12. Default Settings at Wall Boundaries

The default thermal boundary condition is a fixed heat flux of zero. Walls are, by default, not moving.

7.4.15.13. Shear-Stress Calculation Procedure at Wall Boundaries

For no-slip wall conditions, Ansys Fluent uses the properties of the flow adjacent to the wall/fluid boundary to predict the shear stress on the fluid at the wall. In laminar flows this calculation simply depends on the velocity gradient at the wall, while in turbulent flows one of the approaches described in Near-Wall Treatments for Wall-Bounded Turbulent Flows in the Theory Guide is used.

For specified-shear walls, Ansys Fluent will compute the tangential velocity at the boundary.

If you are modeling inviscid flow with Ansys Fluent, all walls use a slip condition, so they are frictionless and exert no shear stress on the adjacent fluid.

7.4.15.13.1. Shear-Stress Calculation in Laminar Flow

In a laminar flow, the wall shear stress is defined by the normal gradient of the tangential velocity at the wall:

$$\vec{\tau}_w = \mu \frac{\partial \vec{v}}{\partial n} \tag{7.122}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When there is a steep velocity gradient at the wall, you must be sure that the mesh is sufficiently fine to accurately resolve the boundary layer. Guidelines for the appropriate placement of the near-wall node in laminar flows are provided in Mesh Element Distribution (p. 1123).

7.4.15.13.2. Shear-Stress Calculation in Turbulent Flows

Wall treatments for turbulent flows are described in Near-Wall Treatments for Wall-Bounded Turbulent Flows in the Theory Guide.

7.4.15.14. Heat Transfer Calculations at Wall Boundaries

7.4.15.14.1. Temperature Boundary Conditions

When a fixed temperature condition is applied at the wall, the heat flux to the wall from a fluid cell is computed as

$$q = h_f\left(T_w - T_f\right) + q_{rad} \tag{7.123}$$

where

h_f = fluid-side local heat transfer coefficient

T_w = wall surface temperature

T_f = local fluid temperature

q_{rad} = radiative heat flux

Note that the fluid-side heat transfer coefficient is computed based on the local flow-field conditions (for example, turbulence level, temperature, and velocity profiles), as described by Equation 7.130 (p. 1460).

Heat transfer to the wall boundary from a solid cell is computed as

$$q = \frac{k_s}{\Delta n}\left(T_w - T_s\right) + q_{rad} \tag{7.124}$$

where

k_s = thermal conductivity of the solid

T_s = local solid temperature

Δn = distance between wall surface and the solid cell center

7.4.15.14.2. Heat Flux Boundary Conditions

When you define a heat flux boundary condition at a wall, you specify the heat flux at the wall surface. Ansys Fluent uses Equation 7.123 (p. 1458) and your input of heat flux to determine the wall surface temperature adjacent to a fluid cell as

$$T_w = \frac{q - q_{rad}}{h_f} + T_f \tag{7.125}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where, as noted above, the fluid-side heat transfer coefficient is computed based on the local flow-field conditions. When the wall borders a solid region, the wall surface temperature is computed as

$$T_w = \frac{\left(q - q_{rad}\right)\Delta n}{k_s} + T_s \tag{7.126}$$

7.4.15.14.3. Convective Heat Transfer Boundary Conditions

When you specify a convective heat transfer coefficient boundary condition at a wall, Ansys Fluent uses your inputs of the external heat transfer coefficient and external heat sink temperature to compute the heat flux to the wall as

$$\begin{aligned} q &= h_f\left(T_w - T_f\right) + q_{rad} \\ &= h_{ext}\left(T_{ext} - T_w\right) \end{aligned} \tag{7.127}$$

where

h_{ext} = external heat transfer coefficient defined by you

T_{ext} = external heat-sink temperature defined by you

q_{rad} = radiative heat flux

Equation 7.127 (p. 1459) assumes a wall of zero-thickness.

7.4.15.14.4. External Radiation Boundary Conditions

When the external radiation boundary condition is used in Ansys Fluent, the heat flux to the wall is computed as

$$\begin{aligned} q &= h_f\left(T_w - T_f\right) + q_{rad} \\ &= \varepsilon_{ext}\sigma\left(T_\infty^4 - T_w^4\right) \end{aligned} \tag{7.128}$$

where

ε_{ext} = emissivity of the external wall surface defined by you

σ = Stefan-Boltzmann constant

T_w = surface temperature of the wall

T_∞ = temperature of the radiation source or sink on the exterior of the domain, defined by you

q_{rad} = radiative heat flux to the wall from within the domain

Equation 7.128 (p. 1459) assumes a wall of zero-thickness.

7.4.15.14.5. Combined External Convection and Radiation Boundary Conditions

When you choose the combined external heat transfer condition, the heat flux to the wall is computed as

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\begin{aligned} q &= h_f\left(T_w - T_f\right) + q_{rad} \\ &= h_{ext}\left(T_{ext} - T_w\right) + \varepsilon_{ext}\sigma\left(T_\infty^4 - T_w^4\right) \end{aligned} \tag{7.129}$$

where the variables are as defined above. Equation 7.129 (p. 1460) assumes a wall of zero-thickness.

7.4.15.14.6. Calculation of the Fluid-Side Heat Transfer Coefficient

In laminar flows, the fluid side heat transfer at walls is computed using Fourier's law applied at the walls. Ansys Fluent uses its discrete form:

$$q = k_f\left(\frac{\partial T}{\partial n}\right)_{wall} \tag{7.130}$$

where n is the local coordinate normal to the wall.

For turbulent flows, Ansys Fluent uses the law-of-the-wall for temperature derived using the analogy between heat and momentum transfer [81] (p. 5659). See Standard Wall Functions in the separate Theory Guide for details.

7.4.16. Perforated Wall Boundary Conditions

7.4.16.1. Overview and Limitations

Perforated walls can be used to introduce low-temperature air into a region operating under very high temperatures to provide efficient cooling of the walls. This is one of the most common techniques used in many industrial applications, such as combustor chambers.

Because perforated walls often have thousands of small holes, resolving every single hole is not practical due to the high computational cost. Ansys Fluent offers a model to account for the effects of air streams injected through the perforated holes.

Note the following limitations of the perforated wall model:

- The perforated wall model considers the effects of perforated holes only on:
  - velocity fields
  - temperature fields (if the energy equation is enabled)
  - species distribution (if the species transport model is enabled)
  - mixture fraction and progress variable distribution (if the PDF model is enabled)
- The perforated wall model is not supported with the density-based solver.
- When the Euler-Euler multiphase flow model is used, the perforated wall model is applied only to the primary phase.
- The effects of the perforated wall model on turbulence are not considered.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.16.2. Modeling Concept

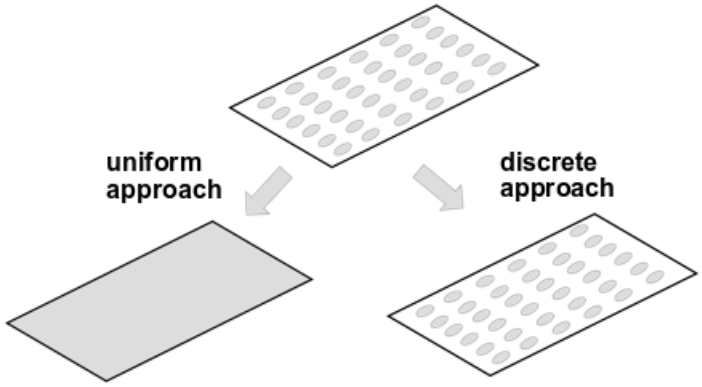
When modeling the effects of perforated holes in Ansys Fluent, solid walls are not meshed. Instead, a flow injection is imposed on the side where the flow is coming out through the perforated hole (hereinafter referred to as the injection side). In order to ensure the mass conservation, the same amount of mass flow is extracted at the side where the flow is coming into the perforated hole (hereinafter referred to as the extraction side).

Figure 7.60: Modeling Perforated Walls

From the perspective of how the perforated walls are treated, there are two approaches to modeling the effects of perforated holes in the flow fields:

- Uniform approach
- Discrete approach

Figure 7.61: Uniform and Discrete Approaches



The uniform approach models the average effect of perforated walls on the flow field. Solid walls with the large number of the perforated holes are treated as having uniform injection conditions. The individual perforated hole is not resolved. Instead, the entire surface of the injection side wall has the same boundary condition of a prescribed mass flux. This approach is based on the rationale that in the preliminary design process, only the first-order effects of perforated walls on the flow field are of interest. This means that only the inviscid streamwise momentum flux and inviscid normal momentum flux due to injection are to be considered.

The discrete approach has more fidelity in modeling perforation holes effects. The individual perforated hole is resolved. In other words, the injections conditions are only imposed at the location of the perforated holes. Although this approach is able to resolve the flow fields at the individual perforated hole level, it does not imply that you need to actually mesh the holes during the

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

meshing process. Instead, all the perforated holes can be marked via the perforated wall model capability in Ansys Fluent as described in Setting Perforated Walls (p. 1463).

Physically, if the perforated holes are fully resolved, the injection conditions at the exit of the holes are determined internally by the flow inside the perforated channel. More specifically, they are determined by the pressure difference between the extraction and injection sides. Therefore, the injection mass flow rate at the hole exit $\dot{m}$ (in kg/s) can be calculated by [12] (p. 5655):

$$\dot{m}=\mathrm{A}C_D\sqrt{2\rho_e\left(p_e-p_i\right)} \tag{7.131}$$

where

A = effective area of the hole channel

C_D = discharging coefficient

ρ_e = density on the extraction side

p_e and p_i = pressures on the extraction side and injection side, respectively

In order to determine the injection mass flow rate, the value of the discharging coefficient C_D must be specified. In some practical scenarios, the product value of $\mathrm{A}C_D$ may be known instead of individual values of A and C_D. In Ansys Fluent, you can specify either C_D or $\mathrm{A}C_D$ as described in Setting Perforated Walls (p. 1463).

Equation 7.131 (p. 1462) assumes that the flow inside the perforated channel is incompressible. If the speed inside the perforated channel is very high, the compressible flow is more adequate to describe the flow behaviors under this circumstance. A compressible formulation for the injection condition is suggested as [9] (p. 5655):

$$\dot{m}=C_D A p_e\sqrt{\frac{2}{RT_e}\frac{\gamma}{\gamma-1}\left(p_{ratio}^{-\frac{2}{\gamma}}-p_{ratio}^{-\frac{\gamma+1}{\gamma}}\right)} \tag{7.132}$$

$$p_{ratio}=\min\left[\frac{p_e}{p_i},\left(\frac{\gamma+1}{2}\right)^{\frac{\gamma}{\gamma-1}}\right]$$

where

R = gas constant

T_e = temperature of the extraction side

γ = heat capacity ratio

Estimating injection condition based on Equation 7.131 (p. 1462) or Equation 7.132 (p. 1462) is referred to as the dynamic method in Ansys Fluent since the injection mass flow rate is estimated based on the local pressure field. Besides the dynamic injection method specification, you can directly specify the injection mass flow rate at the hole exit $\dot{m}$ (in kg/s). This is referred to as the static injection method in Ansys Fluent.

Once the injection mass flow rate is determined via either the dynamic or static injection method, a proper mass flux condition is imposed on the extraction side to ensure mass conservation. After the mass flux condition is determined on the extraction side, the amount of energy and species (or mixture fraction/progress variable) removed on the extraction side can be calculated. As a result,

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the same amount of energy and species is added on the injection side to ensure energy conservation and species mass conservation. For the momentum flux on the injection side, different options can be selected based on the application need.

Note that although the perforated wall model originally comes from the gas turbine combustor applications, it is also applicable to general problems if similar effects on the flow fields need to be accounted for.

7.4.16.3. Setting Perforated Walls

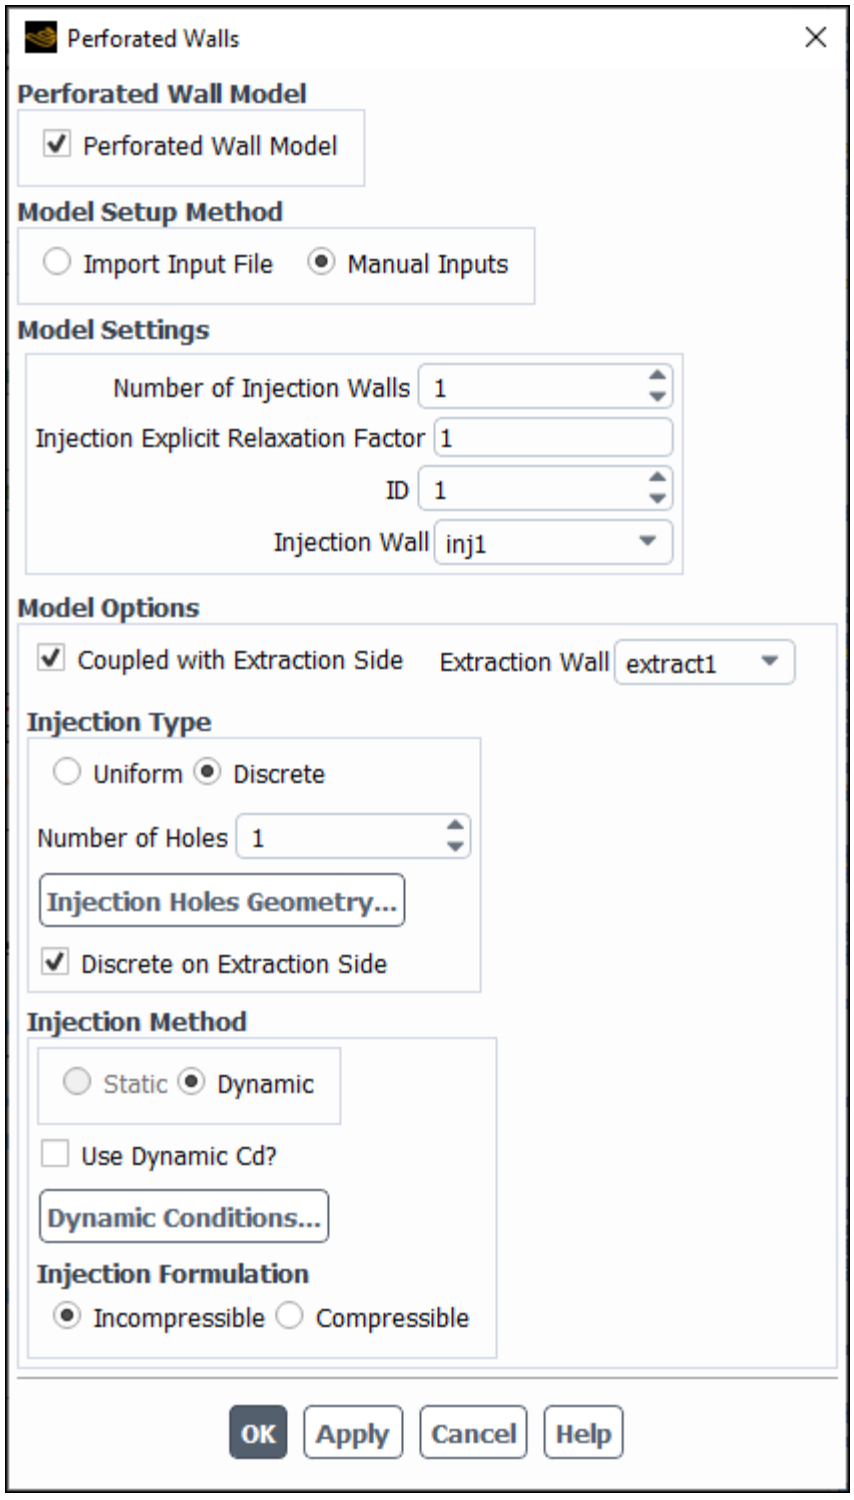
If you want to consider the effects of air streams injected through the perforated holes in your simulation, follow the below steps. Note that the perforated walls model setup is based on the injection side; the extraction side will be handled automatically by Ansys Fluent based on the selected model options.

1. In the **Boundary Conditions** task page, click the **Perforated Wallis...** button.

2. In the **Perforated Walls** dialog box that opens, enable the **Perforated Wall Model** option.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.62: The Perforated Walls Dialog Box



3. Select an appropriate **Model Setup Method** from the following options:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Import Input Files

allows you to read an input file that contains the selections of model options and values of the model parameters. This option is useful for cases where hundreds or even thousands of perforated holes need to be defined.

Manual Inputs

allows you to manually specify perforated wall options and parameters. When this option is selected, the **Perforated Walls** dialog box expands to reveal relevant model inputs.

4. If you have chosen **Import Input File**, use the **Select File** dialog box to read an input file for the perforated wall definition. See Perforated Wall File Format (p. 1471) for the details about input file format and an example of the perforated wall file.

   Once Ansys Fluent reads the file, the data entry fields in the **Injection Holes** and **Dynamic Setup** dialog boxes will be automatically populated with the appropriate information. You can review and edit these settings in each dialog box.

5. If you have chosen **Manual Inputs**, follow the steps outlined in Procedure for Manual Setup of Perforated Walls (p. 1465):

6. Click **OK** to close the **Perforated Walls** dialog box.

7.4.16.4. Procedure for Manual Setup of Perforated Walls

If you have chosen the **Manual Inputs** option in the **Perforated Walls** dialog box (**Model Setup Method** group box), you need to specify the following settings and options:

1. In the **Modeling Settings** group box (see Figure 7.62: The Perforated Walls Dialog Box (p. 1464)), specify the total number of walls where you want to define the perforated wall boundary condition in the **Number of Injection Walls** field. You will need to define boundary conditions for each wall separately.

2. In the **Injection Explicit Relaxation Factor** field, enter a value between 0 and 1 (default = 1).

   This parameter controls the update of the injection mass flow rate at each iteration. It is used to blend the injection mass flow rates calculated by Equation 7.131 (p. 1462) (for an incompressible flow) or Equation 7.132 (p. 1462) (for a compressible flow) at the current and previous iterations. If any convergence issues arise, you can try to lower this factor at the beginning of your run.

3. Set the **ID** of the injection wall. This number must be between 1 and the value specified in **Number of Injection Walls**.

4. From the **Injection Wall** drop-down list, select the name of the injection wall you are defining.

5. If you want to couple the injection and extraction walls, enable **Coupled with Extraction Side**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

With **Coupled with Extraction Side** enabled, Ansys Fluent automatically selects **Dynamic** in the **Injection Method** group box. Otherwise, Ansys Fluent uses the **Static** injection method.

Note:

In the current implementation, you cannot change the injection method (**Static** or **Dynamic**).

6. Select the name of the extraction wall that you want to couple with the injection wall from the **Extraction Wall** drop-down list (**Modeling Options** group box). When the flow is introduced on the injection wall, the same amount of mass is removed from the extraction wall.

7. In the **Injection Type** group box select either **Uniform** or **Discrete** modeling approach. See Modeling Concept (p. 1461) for more information about these two approaches.

8. For the **Discrete** injection type, define the geometry of the injection holes.

   a. In the **Number of Holes** field, set the total number of perforated holes in the injection wall.

   b. Click the **Injection Holes Geometry...** button to specify the injection holes parameters in the **Injection Holes** dialog box that opens.

Figure 7.63: The Injection Holes Dialog Box

   i. Select the **Axes Specification Method** for defining perforated holes:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Point-Point

allows you to specify two arbitrary points on the cylinder axis.

Point-Direction

allows you to specify a point and a direction vector of the cylinder axis.

ii. For each hole with the ID set in the **Hole ID** field, you need to specify the following parameters in the **Hole Geometry** group box (depending on your selection of the **Axes Specification Method**):

- For the **Point-Point** axes specification method:
  - Coordinates of two points on the cylinder axis ((**Point 1 X**, **Point 1 Y**, **Point 1 Z**) and (**Point 2 X**, **Point 2 Y**, **Point 2 Z**))
  - **Diameter**
- For the **Point-Direction** axes specification method:
  - Coordinates of a point on the cylinder axis (**Point X**, **Point Y**, **Point Z**) and a direction vector (**Direction X**, **Direction Y**, **Direction Z**)
  - **Diameter**

Note:

Inputs for the Z coordinate will be displayed for 3D cases only.

Ansys Fluent will automatically find all intersections between the specified cylinders and the injection or extraction wall. Then each face involved in the intersections will be marked as either a hole exit or a hole inlet, respectively.

iii. Click **OK** to close the **Injection Holes** dialog box.

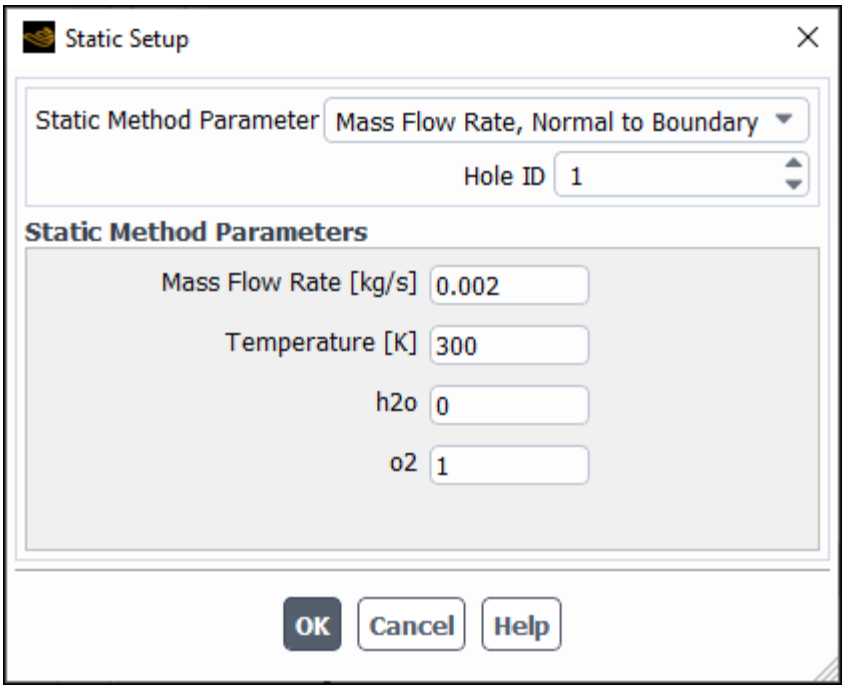
c. If you want to model the uniform condition on the extraction side, disable the **Discrete on Extraction Side** option (default) (**Injection Type** group box).

9. For the **Static** injection method, specify the static method settings.

a. In the **Injection Method** group box, click the **Static Conditions...** button to specify injection settings in the **Static Setup** dialog box that opens.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.64: The Static Setup Dialog Box (Uniform Injection)



b. Select the **Specification Method** from the following options:

Normal to Boundary

defines the injection direction by the normal to the surface of the injection wall.

Direction

defines the injection direction by the three components of the directional vector.

c. For each hole with the ID set in the **Hole ID** field, you need to specify the following parameters in the **Static Method Parameters** group box:

- **Mass Flow Rate**: Injection mass flow rate (kg/s)
- **Temperature**: Injection static temperature (K)
- Mass fractions of species that constitute the mixture material in the injection flow

  In the example shown in Figure 7.64: The Static Setup Dialog Box (Uniform Injection) (p. 1468), the mixture material contains H_2O, O_2, and N_2. In this case, the mixture fraction of **h2o** and **o2** must be specified. The mass fraction of N_2 is computed by subtracting the sum of the remaining mass fractions from unity.

- (**Direction** specification method only) **X Direction**, **Y Direction**, and **Z Direction** (3D only)

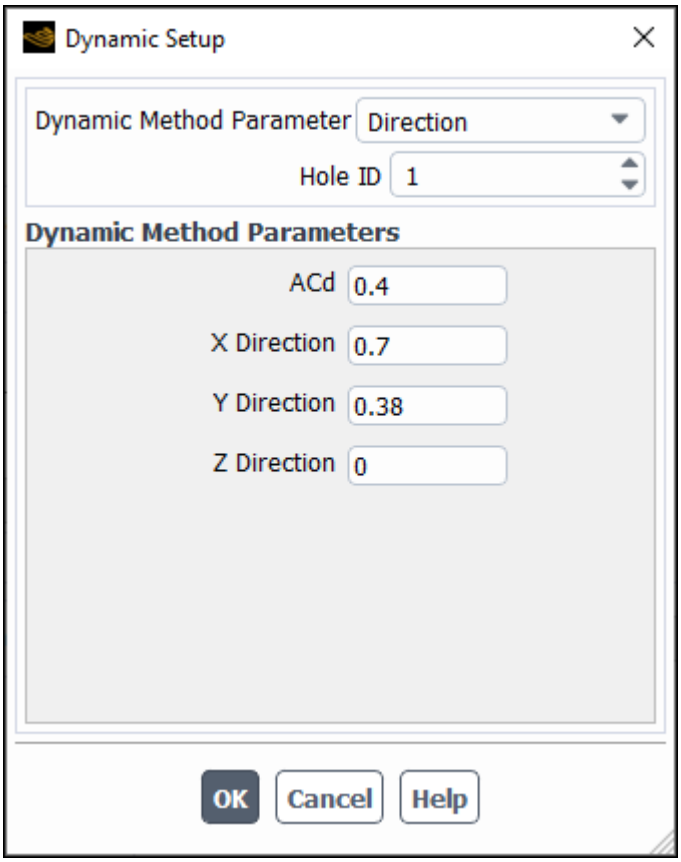
d. Click **OK** to close the **Static Setup** dialog box.

10. For the **Dynamic** injection method, specify the dynamic method settings.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

a. In the **Injection Method** group box, click the **Dynamic Conditions...** button to specify injection settings in the **Dynamic Setup** dialog box that opens.

Figure 7.65: The Dynamic Setup Dialog Box (Uniform Injection)



b. If you have selected the **Uniform** injection type, you need to specify the following:

i. Select the **Dynamic Method Parameter** from the following options:

Normal to Boundary

defines the injection direction by the normal to the surface of the injection wall.

Direction

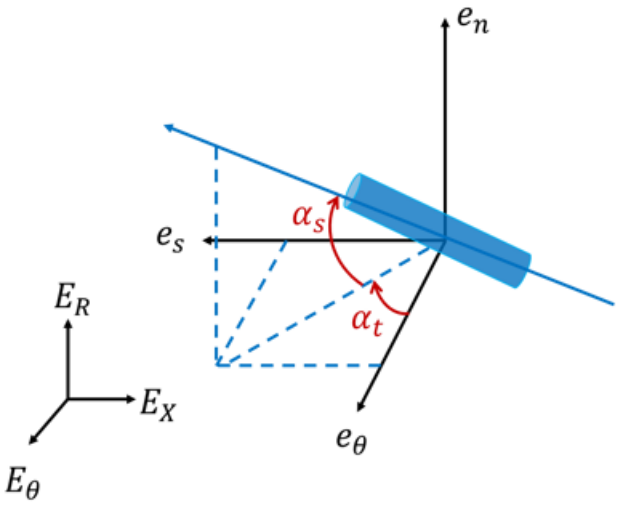
defines the injection direction by the three components of the directional vector.

Injection Angles

defines the injection direction by the surface and tangential angles. These are the angles of the cylinder axis α_s and α_t in the local cylindrical coordinate system (e_n, e_θ, e_s) as shown in Figure 7.66: Injection Surface and Tangential Angles (p. 1470).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.66: Injection Surface and Tangential Angles



The directions of the local cylindrical coordinate system are:

- e_n is the outward normal to the perforated wall surface
- e_θ has the same direction as the circumferential direction E_θ of the global cylindrical coordinate system (E_θ, E_X, E_R), where E_X and E_R are the axial and radial directions, respectively.
- e_s is the direction of the cross product e_s=e_θ×e_n.

ii. For each hole with the ID set in the **Hole ID** field, you need to specify the following parameters in the **Dynamic Method Parameters** group box (depending on your selection of the injection direction method):

- For all injection direction methods: **ACd** (the coefficient AC_D in Equation 7.131 (p. 1462) for an incompressible flow or Equation 7.132 (p. 1462) for a compressible flow)
- For the **Direction** method: Injection direction vector (**X Direction**, **Y Direction**, and **Z Direction**)
- For the **Injection Angles** method: Injection direction angles (**Surface Angle** and **Tangential Angle**)

iii. Click **OK** to close the **Dynamic Setup** dialog box.

c. If you have selected the **Discrete** injection type, you need to specify the following:

i. Select the **Dynamic Method Parameter** from the following options:

Cd

is C_D in Equation 7.131 (p. 1462) for an incompressible flow or Equation 7.132 (p. 1462) for a compressible flow

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ACd

Is AC_D in Equation 7.131 (p. 1462) for an incompressible flow or Equation 7.132 (p. 1462) for an compressible flow

ii. For each hole with the ID set in the **Hole ID** field, you need to enter the value for **Cd** (if you selected **Cd** for the **Dynamic Method Parameter**) or **ACd** (if you selected **ACd** for the **Dynamic Method Parameter**) in the **Dynamic Method Parameters** group box.

d. Click **OK** to close the **Dynamic Setup** dialog box.

e. Select the **Injection Formulation** (**Injection Method** group box) from the following options:

- **Incompressible**: Uses Equation 7.131 (p. 1462) to calculate the injection mass flow rate at the hole exit
- **Compressible**: Uses Equation 7.132 (p. 1462) to calculate the injection mass flow rate at the hole exit

f. (optional) By default, Ansys Fluent uses a constant value for C_D in Equation 7.131 (p. 1462). For the **Discrete** injection type with the **Discrete on Extraction Side** option, you can use a custom formulation for C_D by selecting the **Use Dynamic Cd?** option and hooking your `DEFINE_PERFORATED_CD` UDF to the code. See `DEFINE_PERFORATED_CD` in the *Fluent Customization Manual* for more information.

11. Repeat steps 3-10 for each wall ID where you want to define the perforated wall boundary condition.

7.4.16.5. Perforated Wall File Format

A perforated wall file is an ASCII file containing information for setting a perforated wall boundary condition on selected walls. The file can contain comment lines, which are lines that begin with either a forward slash (`/`), a semicolon (`;`), or an exclamation mark (`!`).

The following is an example of an input file that sets perforated wall boundary conditions on two walls for a 3D case:

```
// Sample Input File for Effusion Cooling Model
// total number of effusion walls (pairs)
2
// URF for mass flow calculations
0.6
//+++++++++++++++++++ First Pair +++++++++++++++++++++++++++
// Injection Wall Name
effusion-down:002
// Coupling Method
// Format: coupled [extraction wall name]
coupled effusion-up
// Injection Type
// "uniform" or "discrete" [cylinder method] [discrete on extraction side?]
discrete point-point ext-discrete
// Injection Method
// "dynamic" [mass flow rate formulation] ("incompressible" or "compressible")
dynamic compressible
// Model Inputs
// The header line starts with a '%', the subsequent lines define injection parameters
%   x1       y1       z1       x2       y2       z2   diameter    cd
0.010000 0.001000 0.010000 0.005000 0.001000 0.011000 0.000500 0.500000

0.032000 0.001000 0.010000 0.027000 0.001000 0.011000 0.000500 0.500000
0.032000 0.002000 0.010000 0.027000 0.002000 0.011000 0.000500 0.500000
...
0.042000 0.010000 0.010000 0.037000 0.010000 0.011000 0.000500 0.500000
```

The format of the perforated wall input file (excluding comment and blank lines) is as follows:

- The first line contains the number of the walls to which you want to assign the perforated wall boundary condition (a single integer number). You will need to define each perforated wall separately.
- Line 2 provides the injection explicit relaxation factor (a single float number between 0 and 1).
- Line 3 is the name of the injection wall. Lines that follow Line 3 contain parameters that define the perforated wall boundary condition for this wall.
- Line 4 contains the following keyword:
  - Model options: `coupled` or `uncoupled`.
  - (`coupled` injections only) The name of the coupled extraction wall.
- Line 5 contains the following keywords:
  - Injection type: `uniform` or `discrete`
  - (`discrete` injection type only) Perforated hole definition method: `point-point` or `point-direction`
  - (`uniform` injection type only) Injection direction definition method: `normal` (normal to boundary), `direction` (direction vector), or `angle` (injection angles)
  - Optional keyword `ext-discrete` for using the discrete condition on the extraction wall

  In the above example, Line 5 specifies the `discrete` injection type, the `point-point` hole definition method, and the `ext-discrete` condition on the extraction wall.
- Line 6 contains the following keywords:
  - Injection method (`static` or `dynamic`)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

– (optional, dynamic injection method only) cd-profile to use a UDF to calculate C_D in Equation 7.131 (p. 1462). If this keyword is not present, Ansys Fluent uses a constant value of C_D.

– (dynamic injection method only) Mass flow rate formulation (incompressible or compressible) described in Equation 7.131 (p. 1462) and Equation 7.132 (p. 1462), respectively.

- Line 7 begins with the percentage character (%) and contains the header information for the perforated wall inputs. The following keywords can be used in the header:

  x, y, z, vx, vy, vz, x1, y1, z1, x2, y2, z2, diameter, nx, ny, nz, alpha-s, alpha-t, mf, tem, fmean, pv, *species names*

  Note:

  The keyword and inputs for the Z coordinate are required for 3D cases only.

  The keywords may be provided in any order. However, the hole and injection data in the subsequent lines must follow the order you have defined in the header line.

  Depending on the selection of the injection type and dynamic conditions, different data must be provided as further described.

- The subsequent lines describe perforated hole parameters. Each line contains input data for each individual hole. The input values and keywords in each line must follow the order you have specified in the header (Line 7). The inputs are described below along with the keywords that must appear in the header line:

  – (discrete injection type only) Hole geometry information:

    → For the point-point hole definition method: the coordinates of two points on the hole axis and the diameter. The header keywords for these variables are:

    x1, y1, z1, x2, y2, z2, diameter

    → For the point-direction hole definition method: the coordinates of the point on the hole axis, the direction vector, and the diameter. The header keywords are:

    x, y, z, vx, vy, vz, diameter

  – (both uniform and discrete injection types) Coefficient for the injection mass flow rate:

    → For the uniform injection type: AC_D (in Equation 7.131 (p. 1462) or Equation 7.132 (p. 1462)). The header keyword is acd.

    → For the discrete injection type: either C_D or AC_D (in Equation 7.131 (p. 1462) or Equation 7.132 (p. 1462)). The header keywords are respectively: cd or acd.

  – (uniform injection type only) Injection direction parameters:

    → For the direction injection direction definition method: the coordinates of the direction vector. The header keywords are: nx, ny, nz.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

→ For the `angle` injection direction definition method: the surface angle and the tangential angle. The header keywords are: `alpha-s`, `alpha-t`.

– (`static` injection method only) Static injection parameters:

→ Mass flow rate of injection wall. The header keyword is `mf`.

→ (if the energy equation is enabled) Temperature of the injection flow. The header keyword is `tem`.

→ (if the species transport model is enabled): Species mass fractions. The header keywords are the species names present in the mixture material. You only need to specify non-zero values of species mass fractions in the injection flow, and the rest of the species in the mixture are automatically assumed to have zero mass fractions.

→ (if the PDF turbulent combustion model is enabled): the mean mixture fraction and/or progress variable. The header keywords are `fmean` and `pv`, respectively.

For example, for the uniform injection with the `angle` direction specification, each line must contain inputs for the following keywords:

```
acd alpha-s alpha-t
```

The number of input lines determines the number of perforated holes in the wall.

- If the perforated wall boundary condition is assigned to more than one wall in your case, provide information for each wall as described above.

7.4.16.6. Postprocessing for Perforated Walls

When the perforated wall model is enabled, you can generate graphical plots or alphanumeric reports of the following field variables. These quantities are available in the **Perforated Walls...** category:

- **Tagged Face**
- **Injection Hole Mass Flow Rate**
- **Injection Pressure**

See Alphabetical Listing of Field Variables and Their Definitions (p. 4171) for their definitions.

7.4.17. Symmetry Boundary Conditions

Symmetry boundary conditions are used when the physical geometry of interest, and the expected pattern of the flow/thermal solution, have mirror symmetry. They can also be used to model zero-shear slip walls in viscous flows. This section describes the treatment of the flow at symmetry planes

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

and provides examples of the use of symmetry. You do not define any boundary conditions at symmetry boundaries, but you must take care to correctly define your symmetry boundary locations.

Important:

At the centerline of an axisymmetric geometry, you should use the axis boundary type rather than the symmetry boundary type, as illustrated in Figure 7.74: Use of an Axis Boundary as the Centerline in an Axisymmetric Geometry (p. 1480). See Axis Boundary Conditions (p. 1480) for details.

7.4.17.1. Examples of Symmetry Boundaries

Symmetry boundaries are used to reduce the extent of your computational model to a symmetric subsection of the overall physical system. Figure 7.67: Use of Symmetry to Model One Quarter of a 3D Duct (p. 1475) and Figure 7.68: Use of Symmetry to Model One Quarter of a Circular Cross-Section (p. 1475) illustrate two examples of symmetry boundary conditions used in this way.

Figure 7.67: Use of Symmetry to Model One Quarter of a 3D Duct

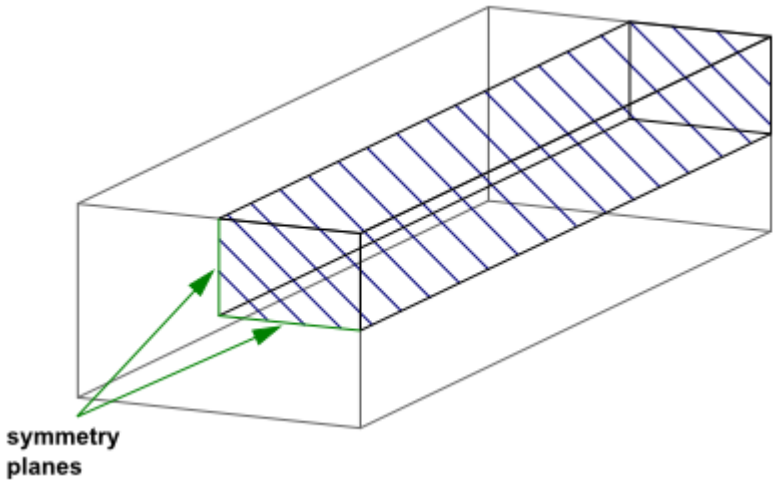

Figure 7.68: Use of Symmetry to Model One Quarter of a Circular Cross-Section

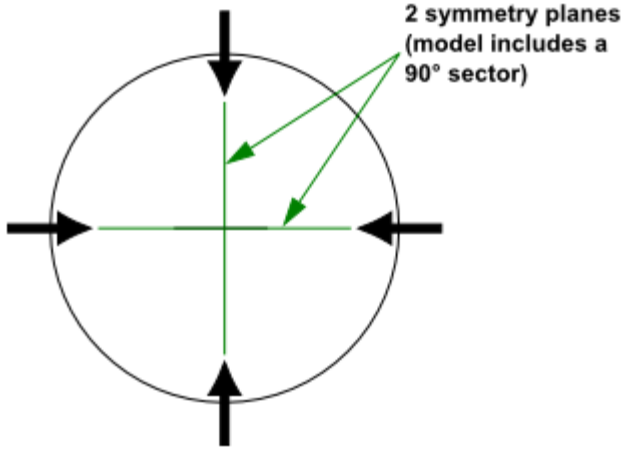

Figure 7.69: Inappropriate Use of Symmetry (p. 1476) illustrates two problems in which a symmetry plane would be *inappropriate*. In both examples, the problem geometry is symmetric but the flow itself does not obey the symmetry boundary conditions. In the first example, buoyancy creates an asymmetric flow. In the second, swirl in the flow creates a flow normal to the would-be symmetry plane. Note that this second example should be handled using rotationally periodic boundaries (as illustrated in Figure 7.70: Use of Periodic Boundaries to Define Swirling Flow in a Cylindrical Vessel (p. 1477)).

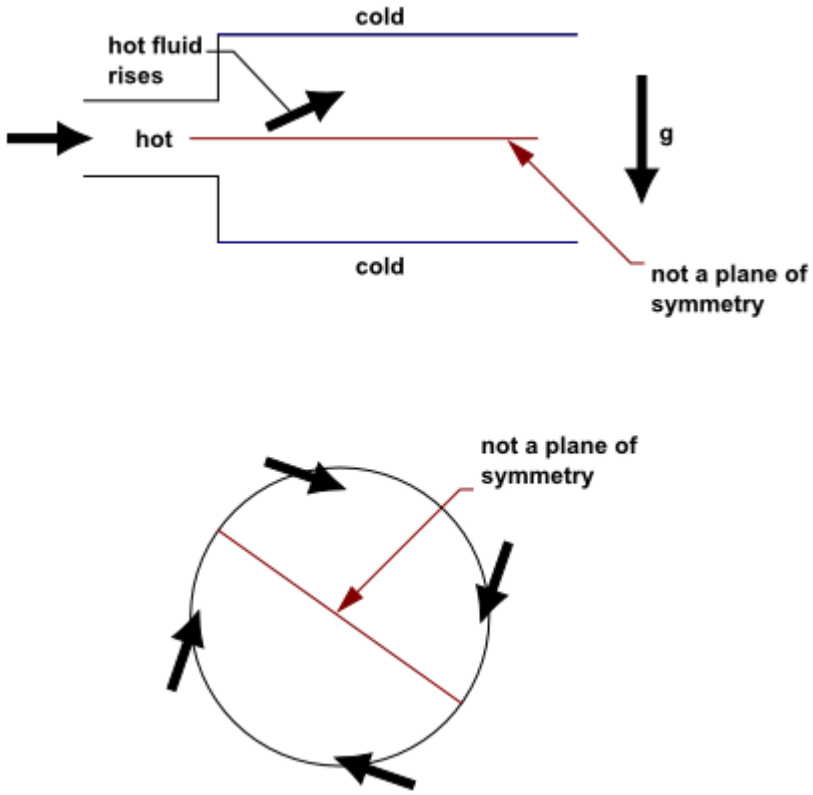
Figure 7.69: Inappropriate Use of Symmetry



7.4.17.2. Calculation Procedure at Symmetry Boundaries

Ansys Fluent assumes a zero flux of all quantities across a symmetry boundary. There is no convective flux across a symmetry plane: the normal velocity component at the symmetry plane is therefore zero. There is no diffusion flux across a symmetry plane: the normal gradients of all flow variables are therefore zero at the symmetry plane. The symmetry boundary condition can therefore be summarized as follows:

- zero normal velocity at a symmetry plane
- zero normal gradients of all variables at a symmetry plane

As stated above, these conditions determine a zero flux across the symmetry plane, which is required by the definition of symmetry. Since the shear stress is zero at a symmetry boundary, it can also be interpreted as a "slip" wall when used in viscous flow calculations.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.18. Periodic Boundary Conditions

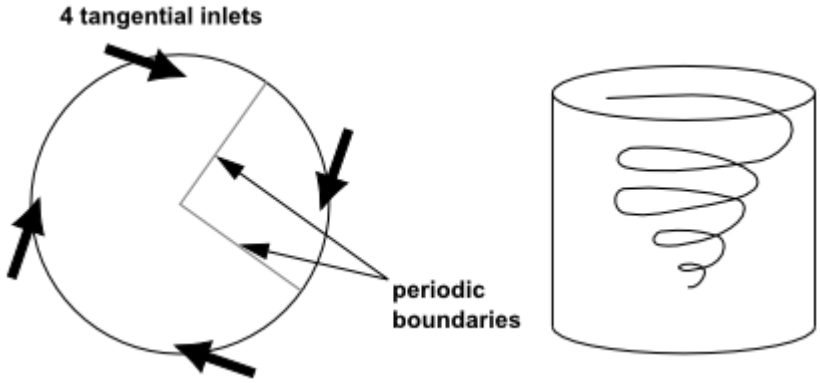
Periodic boundary conditions are used when the physical geometry of interest and the expected pattern of the flow/thermal solution have a periodically repeating nature. Two types of periodic conditions are available in Ansys Fluent. The first type does not allow a pressure drop across the periodic planes. (Note to FLUENT 4 users: This type of periodic boundary is referred to as a "cyclic" boundary in FLUENT 4.) The second type allows a pressure drop to occur across translationally periodic boundaries, enabling you to model "fully-developed" periodic flow. (In FLUENT 4 this is a "periodic" boundary.)

This section discusses the no-pressure-drop periodic boundary condition. A complete description of the fully-developed periodic flow modeling capability is provided in Periodic Flows (p. 1719).

7.4.18.1. Examples of Periodic Boundaries

Periodic boundary conditions are used when the flows across two opposite planes in your computational model are identical. Figure 7.70: Use of Periodic Boundaries to Define Swirling Flow in a Cylindrical Vessel (p. 1477) illustrates a typical application of periodic boundary conditions. In this example the flow entering the computational model through one periodic plane is identical to the flow exiting the domain through the opposite periodic plane. Periodic planes are always used in pairs as illustrated in this example.

Figure 7.70: Use of Periodic Boundaries to Define Swirling Flow in a Cylindrical Vessel



7.4.18.2. Inputs for Periodic Boundaries

For a periodic boundary without any pressure drop, there is only one input you need to consider: whether the geometry is rotationally or translationally periodic. (Additional inputs are required for a periodic flow with a periodic pressure drop. See Periodic Flows (p. 1719).)

Rotationally periodic boundaries are boundaries that form an included angle about the centerline of a rotationally symmetric geometry. Figure 7.70: Use of Periodic Boundaries to Define Swirling Flow in a Cylindrical Vessel (p. 1477) illustrates rotational periodicity. Translationally periodic boundaries are boundaries that form periodic planes in a rectilinear geometry. Figure 7.71: Example of Translational Periodicity - Physical Domain (p. 1478) illustrates translationally periodic boundaries.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.71: Example of Translational Periodicity - Physical Domain

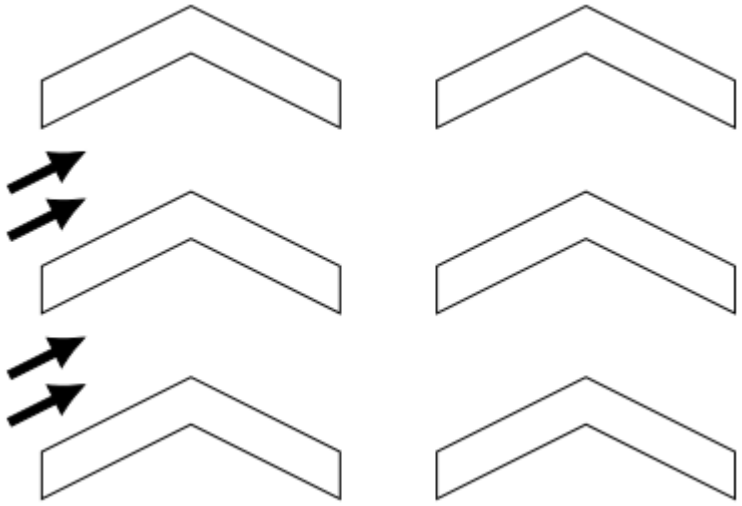


Figure 7.72: Example of Translational Periodicity - Modeled Domain

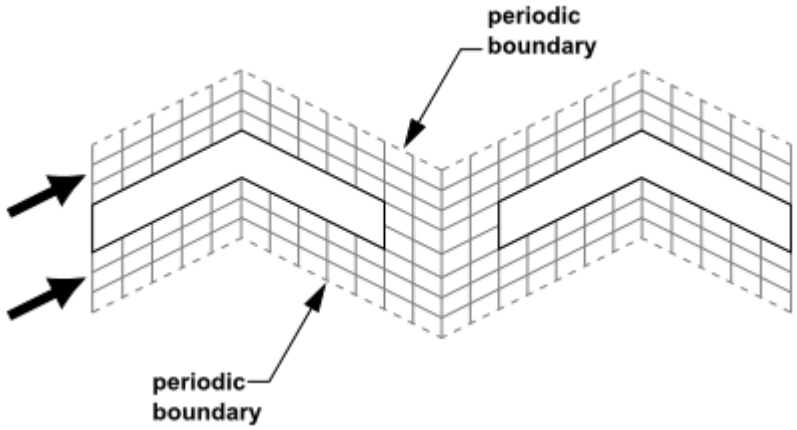
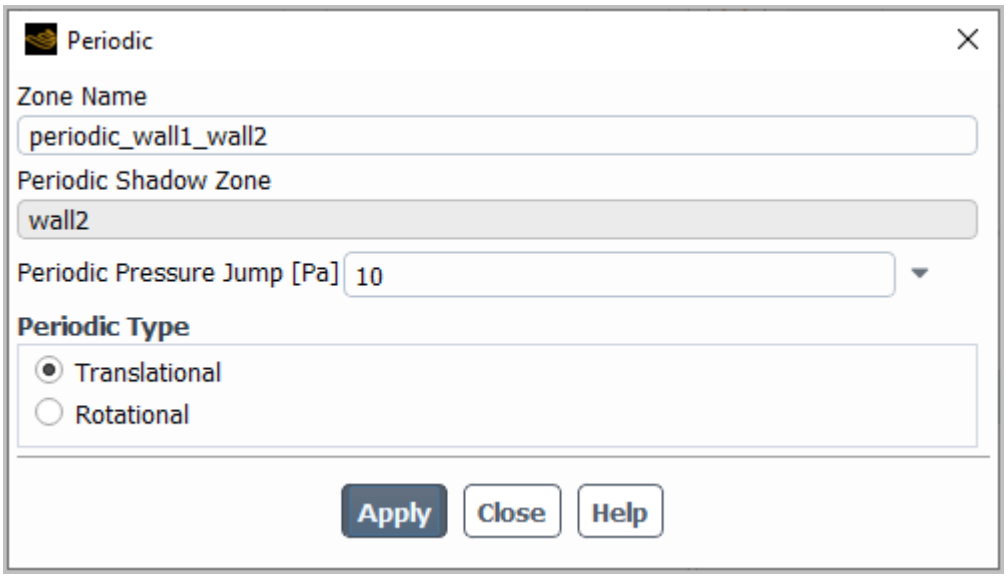


You will specify translational or rotational periodicity for a periodic boundary in the Periodic Dialog Box (p. 4987) (Figure 7.73: The Periodic Dialog Box (p. 1479)), which is opened from the **Boundary Conditions** task page (as described in Setting Cell Zone and Boundary Conditions (p. 1281)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.73: The Periodic Dialog Box



Note that there will be an additional item in the **Periodic** dialog box for the density-based solver, which allows you to specify the periodic pressure jump. See Periodic Flows (p. 1719) for details.

If the domain is rotationally periodic, select **Rotational** as the **Periodic Type**; if it is translationally periodic, select **Translational**. For rotationally periodic domains, the solver will automatically compute the angle through which the periodic zone is rotated. The axis used for this rotation is the axis of rotation specified for the adjacent cell zone.

Note that there is no need for the adjacent cell zone to be moving for you to use a rotationally periodic boundary. You could, for example, model pipe flow in 3D using a stationary reference frame with a pie-slice of the pipe; the sides of the slice would require rotational periodicity.

Click the **Check** button in the **Mesh** group box of the **Domain** tab (see Checking the Mesh (p. 1222)) to compute and display the minimum, maximum, and average rotational angles of all faces on periodic boundaries. If the difference between the minimum, maximum, and average values is not negligible, then there is a problem with the mesh: the mesh geometry is not periodic about the specified axis.

7.4.18.3. Default Settings at Periodic Boundaries

By default, all periodic boundaries are translational.

7.4.18.4. Calculation Procedure at Periodic Boundaries

Ansys Fluent treats the flow at a periodic boundary as though the opposing periodic plane is a direct neighbor to the cells adjacent to the first periodic boundary. Therefore, when calculating the flow through the periodic boundary adjacent to a fluid cell, the flow conditions at the fluid cell adjacent to the opposite periodic plane are used.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

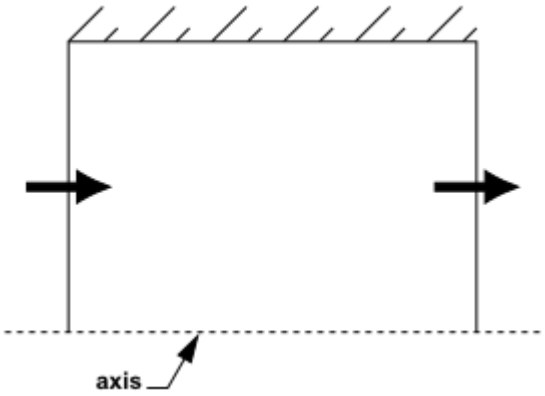
7.4.19. Axis Boundary Conditions

The axis boundary type must be used as the centerline of an axisymmetric geometry (see Figure 7.74: Use of an Axis Boundary as the Centerline in an Axisymmetric Geometry (p. 1480)). It can also be used for the centerline of a cylindrical-polar quadrilateral or hexahedral mesh (for example, a mesh created for a structured-mesh code such as FLUENT 4). You do not need to define any boundary conditions at axis boundaries.

Important:

When creating 2D axisymmetric geometry, the axis boundary must lie on the y=0 line.

Figure 7.74: Use of an Axis Boundary as the Centerline in an Axisymmetric Geometry



7.4.19.1. Calculation Procedure at Axis Boundaries

To determine the appropriate physical value for a particular variable at a point on the axis, Ansys Fluent uses the cell value in the adjacent cell.

7.4.20. Fan Boundary Conditions

The fan model is a lumped parameter model that can be used to determine the impact of a fan with known characteristics upon some larger flow field. The fan boundary type allows you to input an empirical fan curve that governs the relationship between head (pressure rise) and flow rate (velocity) across a fan element. You can also specify radial and tangential components of the fan swirl velocity. The fan model does not provide an accurate description of the detailed flow through the fan blades. Instead, it predicts the amount of flow through the fan. Fans may be used in conjunction with other flow sources, or as the sole source of flow in a simulation. In the latter case, the system flow rate is determined by the balance between losses in the system and the fan curve.

Ansys Fluent also provides a connection for a special user-defined fan model that updates the pressure jump function during the calculation. This feature is described in User-Defined Fan Model (p. 1532).

7.4.20.1. Limitations of Fan Boundary Conditions

The following are limitations when using fan boundary conditions:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- By default, fan boundaries are included in the solar flux calculation when using the Solar Load model with no option to disable.

7.4.20.2. Fan Equations

7.4.20.2.1. Modeling the Pressure Rise Across the Fan

A fan is considered to be infinitely thin, and the discontinuous pressure rise across it is specified as a function of the velocity through the fan. The relationship may be a constant, a polynomial, piecewise-linear, or piecewise-polynomial function, or a user-defined function.

In the case of a polynomial, the relationship is of the form

$$\Delta p = \sum_{n=1}^{N} f_n v^{n-1} \tag{7.133}$$

where Δp is the pressure jump, f_n are the pressure-jump polynomial coefficients, and v is the magnitude of the local fluid velocity normal to the fan.

Important:

The velocity v can be either positive or negative. You must be careful to model the fan so that a pressure rise occurs for forward flow through the fan.

You can, optionally, use the mass-averaged velocity normal to the fan to determine a single pressure-jump value for all faces in the fan zone.

7.4.20.2.2. Modeling the Fan Swirl Velocity

For three-dimensional problems, the values of the convected tangential and radial velocity fields can be imposed on the fan surface to generate swirl. These velocities can be specified as functions of the radial distance from the fan center. The relationships may be constant or polynomial functions, or user-defined functions.

Important:

You must use SI units for all fan swirl velocity inputs.

For the case of polynomial functions, the tangential and radial velocity components can be specified by the following equations:

$$U_\theta = \sum_{n=-1}^{N} f_n r^n; -1 \le N \le 6 \tag{7.134}$$

$$U_r = \sum_{n=-1}^{N} g_n r^n; -1 \le N \le 6 \tag{7.135}$$

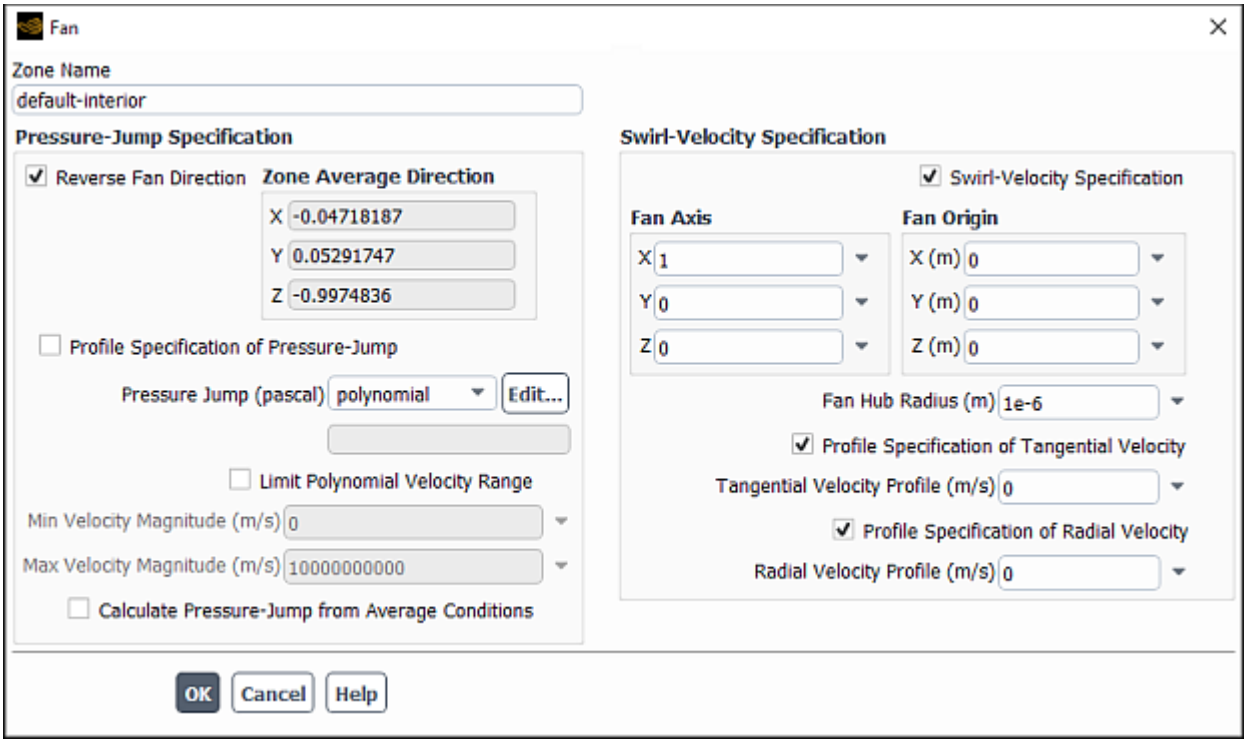
where U_θ and U_r are, respectively, the tangential and radial velocities on the fan surface in m/s, f_n and g_n are the tangential and radial velocity polynomial coefficients, and r is the distance to the fan center.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.20.3. User Inputs for Fans

Once the fan zone has been identified (in the **Boundary Conditions** task page), you will set all modeling inputs for the fan in the Fan Dialog Box (p. 4948) (Figure 7.75: The Fan Dialog Box (p. 1482)), which is opened from the Boundary Conditions Task Page (p. 4937) (as described in Setting Cell Zone and Boundary Conditions (p. 1281)).

Figure 7.75: The Fan Dialog Box



Inputs for a fan are as follows:

1. Identify the fan zone.
2. Define the pressure jump across the fan.
3. Define the discrete phase boundary condition for the fan (for discrete phase calculations).
4. Define the swirl velocity, if desired (3D only).

7.4.20.3.1. Identifying the Fan Zone

Since the fan is considered to be infinitely thin, it must be modeled as the interface between cells, rather than a cell zone. Therefore the fan zone is a type of internal face zone (where the faces are line segments in 2D or triangles/quadrilaterals in 3D). If, when you read your mesh into Ansys Fluent, the fan zone is identified as an **interior** zone, right-click the zone in the tree and use the **Type** sub-menu to change it to a **fan** zone (for more details, see Changing Cell and Boundary Zone Types (p. 1279)).

Once the interior zone has been changed to a fan zone, you can open the **Fan** dialog box and specify the pressure jump and, optionally, the swirl velocity.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.20.3.2. Defining the Pressure Jump

To define the pressure jump, you will specify a polynomial, piecewise-linear, or piecewise-polynomial function of velocity, a user-defined function, or a constant value. You should also check the **Zone Average Direction** vector to be sure that a pressure rise occurs for forward flow through the fan. The **Zone Average Direction**, calculated by the solver, is the face-averaged direction vector for the fan zone. If this vector is pointing in the direction you want the fan to blow, do not select **Reverse Fan Direction**; if it is pointing in the opposite direction, select **Reverse Fan Direction**.

7.4.20.3.2.1. Polynomial, Piecewise-Linear, or Piecewise-Polynomial Function

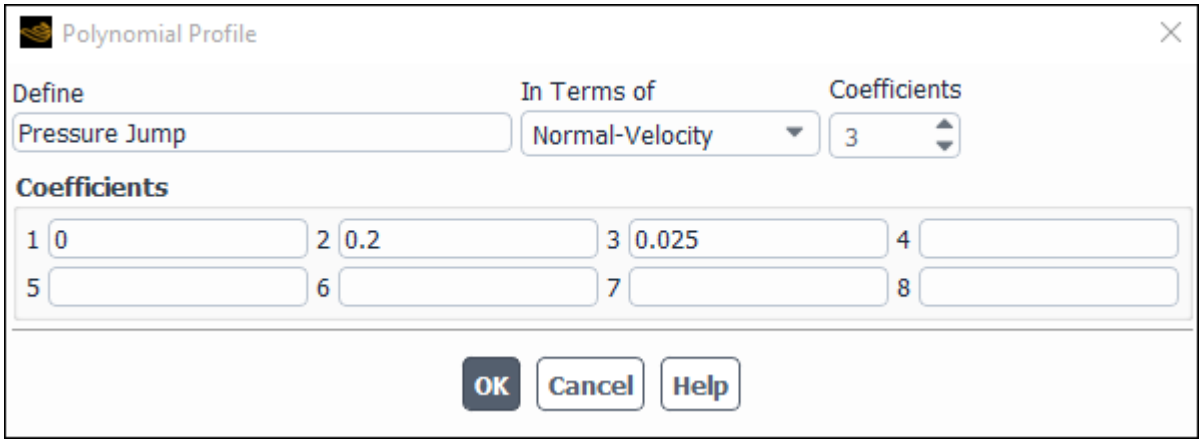
Follow these steps to set a polynomial, piecewise-linear, or piecewise-polynomial function for the pressure jump:

1. Check that the **Profile Specification of Pressure-Jump** option is off in the Fan Dialog Box (p. 4948).

2. Choose **polynomial**, **piecewise-linear**, or **piecewise-polynomial** in the drop-down list to the right of **Pressure-Jump**. (If the function type you want is already selected, you can click the **Edit...** button to open the dialog box where you will define the function.)

3. In the dialog box that appears for the definition of the **Pressure Jump** function (for example, Figure 7.76: Polynomial Profile Dialog Box for Pressure Jump Definition (p. 1483)), enter the appropriate values. These profile input dialog boxes are used the same way as the profile input dialog boxes for temperature-dependent properties. See Defining Properties Using Temperature-Dependent Functions (p. 1590) to find out how to use them.

   Figure 7.76: Polynomial Profile Dialog Box for Pressure Jump Definition



4. Set any of the optional parameters described below. (optional)

When you define the pressure jump using any of these types of functions, you can choose to limit the minimum and maximum velocity magnitudes used to calculate the pressure jump.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Enabling the **Limit Polynomial Velocity Range** option limits the pressure jump when a **Min Velocity Magnitude** and a **Max Velocity Magnitude** are specified.

Important:

The values corresponding to the **Min Velocity Magnitude** and the **Max Velocity Magnitude** do not limit the flow field velocity to this range. However, this range does limit the value of the pressure jump, which is a polynomial and a function of velocity, as seen in Equation 7.133 (p. 1481). If the calculated normal velocity magnitude exceeds the **Max Velocity Magnitude** that has been specified, then the pressure jump at the **Max Velocity Magnitude** value will be used. Similarly, if the calculated velocity is less than the specified **Min Velocity Magnitude**, the pressure jump at the **Min Velocity Magnitude** will be substituted for the pressure jump corresponding to the calculated velocity.

You also have the option to use the mass-averaged velocity normal to the fan to determine a single pressure-jump value for all faces in the fan zone. Turning on **Calculate Pressure-Jump from Average Conditions** enables this option.

7.4.20.3.2.2. Constant Value

To define a constant pressure jump, follow these steps:

1. Turn off the **Profile Specification of Pressure-Jump** option in the Fan Dialog Box (p. 4948).
2. Choose **constant** in the drop-down list to the right of **Pressure-Jump**.
3. Enter the value for Δp in the **Pressure-Jump** field.

You can follow the procedure below, if it is more convenient:

1. Turn on the **Profile Specification of Pressure-Jump** option.
2. Select **constant** in the drop-down list below **Pressure Jump Profile**, and enter the value for Δp in the **Pressure Jump Profile** field.

7.4.20.3.2.3. User-Defined Function or Profile

For a user-defined pressure-jump function or a function defined in a boundary profile file, you will follow these steps:

1. Turn on the **Profile Specification of Pressure-Jump** option.
2. Choose the appropriate function in the drop-down list below **Pressure Jump Profile**.

Important:

The profile must be written in ascending order with smallest pressure jump listed at the top. See Example: Determining the Pressure Jump Function (p. 1485).

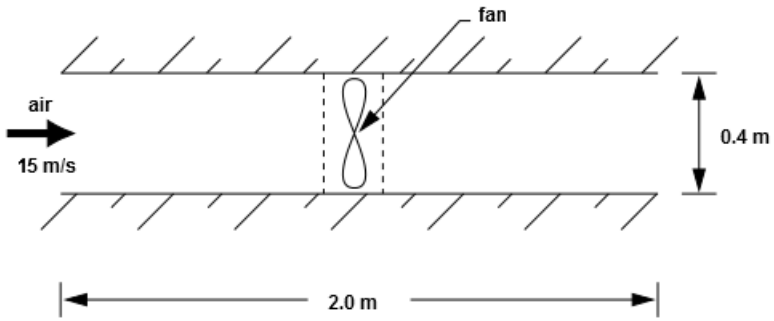
See the Fluent Customization Manual for information about user-defined functions, and Profiles (p. 1540) for details about profile files.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.20.3.2.4. Example: Determining the Pressure Jump Function

This example shows you how to determine the function for the pressure jump. Consider the simple two-dimensional duct flow illustrated in Figure 7.77: A Fan Located In a 2D Duct (p. 1485). Air at constant density enters the 2.0 m × 0.4 m duct with a velocity of 15 m/s. Centered in the duct is a fan.

Figure 7.77: A Fan Located In a 2D Duct



Assume that the fan characteristics are as follows when the fan is operating at 2000 rpm:

Q (m^3 /s)	Δp (Pa)
25	0.0
20	175
15	350
10	525
5	700
0	875

where Q is the flow through the fan and Δp is the pressure rise across the fan. The fan characteristics in this example follow a simple linear relationship between pressure rise and flow rate. To convert this into a relationship between pressure rise and velocity, the cross-sectional area of the fan must be known. In this example, assuming that the duct is 1.0 m deep, this area is 0.4 m^2, so that the corresponding velocity values are as follows:

v (m/s)	Δp (Pa)
62.5	0.0
50.0	175
37.5	350
25.0	525
12.5	700
0	875

The polynomial form of this relationship is the following equation for a line:

$$\Delta p = 875 - 14v \tag{7.136}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.20.3.3. Defining Discrete Phase Boundary Conditions for the Fan

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the fan. See Setting Boundary Conditions for the Discrete Phase (p. 2776) for details.

7.4.20.3.4. Defining the Fan Swirl Velocity

If you want to set tangential and radial velocity fields on the fan surface to generate swirl in a 3D problem, follow these steps:

1. Turn on the **Swirl-Velocity Specification** option in the Fan Dialog Box (p. 4948).
2. Specify the fan's axis of rotation by defining the axis origin (**Fan Origin**) and direction vector (**Fan Axis**).
3. Set the value for the radius of the fan's hub (**Fan Hub Radius**). The default is 1×10^{-6} to avoid division by zero in the polynomial.
4. Set the tangential and radial velocity functions as polynomial functions of radial distance, constant values, or user-defined functions.

Important:

You must use SI units for all fan swirl velocity inputs.

7.4.20.3.4.1. Polynomial Function

To define a polynomial function for tangential or radial velocity, follow the steps below:

1. Check that the **Profile Specification of Tangential Velocity** or **Profile Specification of Radial Velocity** option is off in the Fan Dialog Box (p. 4948).
2. Enter the coefficients f_n in Equation 7.134 (p. 1481) or g_n in Equation 7.135 (p. 1481) in the **Tangential-** or **Radial-Velocity Polynomial Coefficients** field. Enter f_{-1} first, then f_0, and so on. Separate each coefficient by a blank space. Remember that the first coefficient is for $\frac{1}{r}$.

7.4.20.3.4.2. Constant Value

To define a constant tangential or radial velocity, the steps are as follows:

1. Turn on the **Profile Specification of Tangential Velocity** or **Profile Specification of Radial Velocity** option in the Fan Dialog Box (p. 4948).
2. Select **constant** in the drop-down list under **Tangential** or **Radial Velocity Profile**.
3. Enter the value for U_θ or U_r in the **Tangential** or **Radial Velocity Profile** field.

You can follow the procedure below, if it is more convenient:

1. Turn off the **Profile Specification of Tangential Velocity** or **Profile Specification of Radial Velocity** option in the Fan Dialog Box (p. 4948).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Enter the value for U_θ or U_r in the **Tangential-** or **Radial-Velocity Polynomial Coefficients** field.

7.4.20.3.4.3. User-Defined Function or Profile

For a user-defined tangential or radial velocity function or a function contained in a profile file, follow the procedure below:

1. Turn on the **Profile Specification of Tangential** or **Radial Velocity** option.

2. Choose the appropriate function from the drop-down list under **Tangential** or **Radial Velocity Profile**.

See the Fluent Customization Manual for information about user-defined functions, and Profiles (p. 1540) for details about profile files.

7.4.20.4. Postprocessing for Fans

7.4.20.4.1. Reporting the Pressure Rise Through the Fan

You can use the Surface Integrals Dialog Box (p. 5271) to report the pressure rise through the fan, as described in Surface Integration (p. 4116). There are two steps to this procedure:

1. Create a surface on each side of the fan zone. Use the Transform Surface Dialog Box (p. 5575) (as described in Transforming Surfaces (p. 3823)) to translate the fan zone slightly upstream and slightly downstream to create two new surfaces.

2. In the **Surface Integrals** dialog box, report the average **Static Pressure** just upstream and just downstream of the fan. You can then calculate the pressure rise through the fan.

7.4.20.4.2. Graphical Plots

Graphical reports of interest with fans are as follows:

- Contours or profiles of **Static Pressure** and **Static Temperature**.
- XY plots of **Static Pressure** and **Static Temperature** vs position.

Displaying Graphics (p. 3847) explains how to generate graphical displays of data.

Important:

When generating these plots, be sure to turn off the display of node values so that you can see the different values on each side of the fan. (If you display node values, the cell values on either side of the fan will be averaged to obtain a node value, and you will not see, for example, the pressure jump across the fan.)

7.4.21. Radiator Boundary Conditions

A lumped-parameter model for a heat exchange element (for example, a radiator or condenser), is available in Ansys Fluent. The radiator boundary type allows you to specify both the pressure drop and heat transfer coefficient as functions of the velocity normal to the radiator.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A more detailed heat exchanger model is also available in Ansys Fluent. See Modeling Heat Exchangers (p. 2243) for details.

7.4.21.1. Radiator Equations

7.4.21.1.1. Modeling the Pressure Loss Through a Radiator

A radiator is considered to be infinitely thin, and the pressure drop through the radiator is assumed to be proportional to the dynamic head of the fluid, with an empirically determined loss coefficient that you supply. That is, the pressure drop, Δp, varies with the normal component of velocity through the radiator, v, as follows:

$$\Delta p = k_L \frac{1}{2} \rho v^2 \tag{7.137}$$

where ρ is the fluid density, and k_L is the non-dimensional loss coefficient, which can be specified as a constant or as a polynomial, piecewise-linear, or piecewise-polynomial function.

In the case of a polynomial, the relationship is of the form

$$k_L = \sum_{n=1}^{N} r_n v^{n-1} \tag{7.138}$$

where r_n are polynomial coefficients and v is the magnitude of the local fluid velocity normal to the radiator.

7.4.21.1.2. Modeling the Heat Transfer Through a Radiator

The heat flux from the radiator to the surrounding fluid is given as

$$q = h\left(T_{ext} - T_{air,d}\right) \tag{7.139}$$

where q is the heat flux, $T_{air,d}$ is the temperature downstream of the heat exchanger (radiator), and T_{ext} is the radiator temperature. The convective heat transfer coefficient, h, can be specified as a constant or as a polynomial, piecewise-linear, or piecewise-polynomial function.

For a polynomial, the relationship is of the form

$$h = \sum_{n=0}^{N} h_n v^n \quad ; \quad 0 \le N \le 7 \tag{7.140}$$

where h_n are polynomial coefficients and v is the magnitude of the local fluid velocity normal to the radiator in m/s.

To define the actual heat flux $\left(q\right)$, specify a **Temperature** of absolute zero (0 K, 0 °R, –273.15 °C, –459.67 °F), and set the constant **Heat Flux** value.

To define the radiator temperature, enter the value for T_{ext} in the **Temperature** field. To define the **Heat-Transfer-Coefficient** $\left(h\right)$, you can specify a polynomial, piecewise-linear, or piecewise-polynomial function of velocity, or a constant value.

q (either the entered value or the value calculated using Equation 7.139 (p. 1488)) is integrated over the radiator surface area.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Fluent does not allow you to specify a value less than absolute zero for the radiator temperature.

7.4.21.1.2.1. Calculating the Heat Transfer Coefficient

To model the thermal behavior of the radiator, you must supply an expression for the heat transfer coefficient, h, as a function of the fluid velocity through the radiator, v. To obtain this expression, consider the heat balance equation:

$$q=\frac{\dot{m}c_p\Delta T}{A}=h\left(T_{air,d}-T_{ext}\right) \tag{7.141}$$

where

q = heat flux (W/ m^2)

$\dot{m}$ = fluid mass flow rate (kg/s)

c_p = specific heat capacity of fluid (J/kg-K)

h = empirical heat transfer coefficient (W/ m^2 -K)

T_{ext} = external temperature (reference temperature for the liquid) (K)

$T_{air,d}$ = temperature downstream from the heat exchanger (K)

A = heat exchanger frontal area (m^2)

Equation 7.141 (p. 1489) can be rewritten as

$$q=\frac{\dot{m}c_p\left(T_{air,u}-T_{air,d}\right)}{A}=h\left(T_{air,d}-T_{ext}\right) \tag{7.142}$$

where $T_{air,u}$ is the upstream air temperature. The heat transfer coefficient, h, can therefore be computed as

$$h=\frac{\dot{m}c_p\left(T_{air,u}-T_{air,d}\right)}{A\left(T_{air,d}-T_{ext}\right)} \tag{7.143}$$

or, in terms of the fluid velocity,

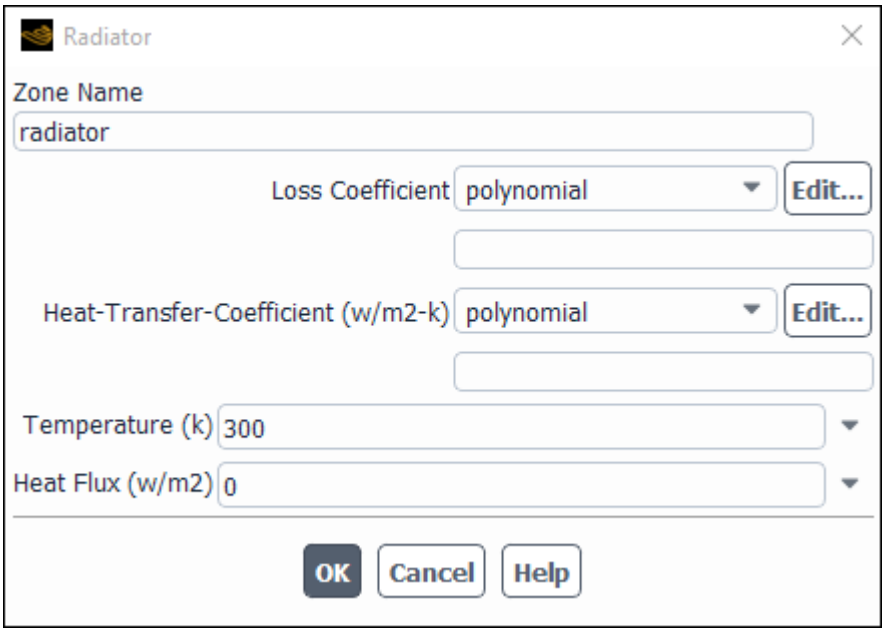
$$h=\frac{\rho vc_p\left(T_{air,u}-T_{air,d}\right)}{T_{air,d}-T_{ext}} \tag{7.144}$$

7.4.21.2. User Inputs for Radiators

Once the radiator zone has been identified (in the **Boundary Conditions** task page), you will set all modeling inputs for the radiator in the Radiator Dialog Box (p. 5015) (Figure 7.78: The Radiator Dialog Box (p. 1490)), which is opened from the Boundary Conditions Task Page (p. 4937) (as described in Setting Cell Zone and Boundary Conditions (p. 1281)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.78: The Radiator Dialog Box



The inputs for a radiator are as follows:

1. Identify the radiator zone.
2. Define the pressure loss coefficient.
3. Define either the heat flux or the heat transfer coefficient and radiator temperature.

   If defining the heat flux, specify the **Temperature** *as absolute zero.*
4. Define the discrete phase boundary condition for the radiator (for discrete phase calculations).

7.4.21.2.1. Identifying the Radiator Zone

Since the radiator is considered to be infinitely thin, it must be modeled as the interface between cells, rather than a cell zone. Therefore the radiator zone is a type of internal face zone (where the faces are line segments in 2D or triangles/quadrilaterals in 3D). If, when you read your mesh into Ansys Fluent, the radiator zone is identified as an **interior** zone, right-click the zone in the tree and use the **Type** sub-menu to change it to a **radiator** zone (for more details, see Changing Cell and Boundary Zone Types (p. 1279)).

Once the interior zone has been changed to a radiator zone, you can open the **Radiator** dialog box and specify the loss coefficient and heat flux information.

7.4.21.2.2. Defining the Pressure Loss Coefficient Function

To define the pressure loss coefficient k_L you can specify a polynomial, piecewise-linear, or piecewise-polynomial function of velocity, or a constant value.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

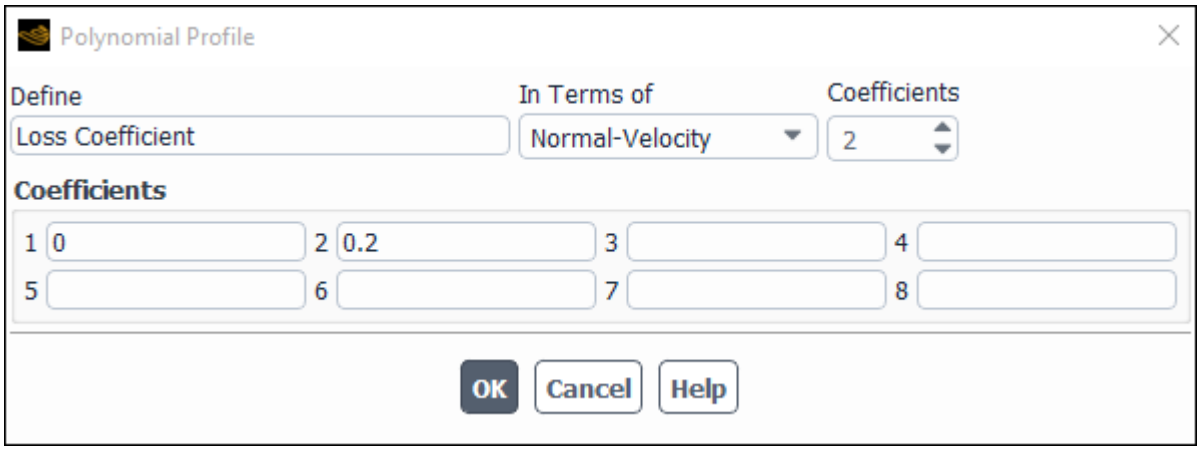
7.4.21.2.2.1. Polynomial, Piecewise-Linear, or Piecewise-Polynomial Function

Follow these steps to set a polynomial, piecewise-linear, or piecewise-polynomial function for the pressure loss coefficient:

1. Choose **polynomial**, **piecewise-linear**, or **piecewise-polynomial** in the drop-down list to the right of **Loss Coefficient**. (If the function type you want is already selected, you can click the **Edit...** button to open the dialog box where you will define the function.)

2. In the dialog box that appears for the definition of the **Loss Coefficient** function (for example, Figure 7.79: Polynomial Profile Dialog Box for Loss Coefficient Definition (p. 1491)), enter the appropriate values. These profile input dialog boxes are used the same way as the profile input dialog boxes for temperature-dependent properties. See Defining Properties Using Temperature-Dependent Functions (p. 1590) to find out how to use them.

Figure 7.79: Polynomial Profile Dialog Box for Loss Coefficient Definition



7.4.21.2.2.2. Constant Value

To define a constant loss coefficient, follow these steps:

1. Choose **constant** in the **Loss Coefficient** drop-down list.

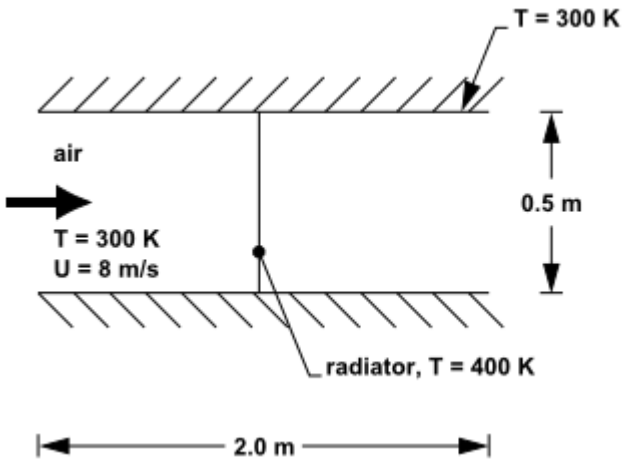
2. Enter the value for k_L in the **Loss Coefficient** field.

7.4.21.2.2.3. Example: Calculating the Loss Coefficient

This example shows you how to determine the loss coefficient function. Consider the simple two-dimensional duct flow of air through a water-cooled radiator, shown in Figure 7.80: A Simple Duct with a Radiator (p. 1492).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.80: A Simple Duct with a Radiator



The radiator characteristics must be known empirically. For this case, assume that the radiator to be modeled yields the test data shown in Table 7.2: Air-side Radiator Data (p. 1492), which was taken with a waterside flow rate of 7 kg/min and an inlet water temperature of 400.0 K. To compute the loss coefficient, it is helpful to construct a table with values of the dynamic head, $\frac{1}{2}\rho v^2$, as a function of pressure drop, Δp, and the ratio of these two values, k_L (from Equation 7.137 (p. 1488)). (The air density, defined in Figure 7.80: A Simple Duct with a Radiator (p. 1492), is 1.0 kg/ m^3.) The reduced data are shown in Table 7.3: Reduced Radiator Data (p. 1492).

Table 7.2: Air-side Radiator Data

Velocity (m/s)	Upstream Temp (K)	Downstream Temp (K)	Pressure Drop
5.0	300.0	330.0	75.0
10.0	300.0	322.5	250.0
15.0	300.0	320.0	450.0

Table 7.3: Reduced Radiator Data

v (m/s)	$\frac{1}{2}\rho v^2$ (Pa)	Δp (Pa)	k_L
5.0	12.5	75.0	6.0
10.0	50.0	250.0	5.0
15.0	112.5	450.0	4.0

The loss coefficient is a linear function of the velocity, decreasing as the velocity increases. The form of this relationship is

$$k_L = 7.0 - 0.2v \tag{7.145}$$

where v is now the absolute value of the velocity through the radiator.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.4.21.2.3. Defining the Heat Flux Parameters

As mentioned in Radiator Equations (p. 1488), you can either define the actual heat flux (q) in the **Heat Flux** field, or set the heat transfer coefficient and radiator temperature (h, T_{ext}). All inputs are in the Radiator Dialog Box (p. 5015).

To define the actual heat flux, specify a **Temperature** of `0` K, and set the constant **Heat Flux** value.

To define the radiator temperature, enter the value for T_{ext} in the **Temperature** field. To define the **Heat-Transfer-Coefficient**, you can specify a polynomial, piecewise-linear, or piecewise-polynomial function of velocity, or a constant value.

7.4.21.2.3.1. Polynomial, Piecewise-Linear, or Piecewise-Polynomial Function

Follow these steps to set a polynomial, piecewise-linear, or piecewise-polynomial function for the heat transfer coefficient:

1. Choose **polynomial**, **piecewise-linear**, or **piecewise-polynomial** in the drop-down list to the right of **Heat-Transfer-Coefficient**. (If the function type you want is already selected, you can click the **Edit...** button to open the dialog box where you will define the function.)

2. In the dialog box that appears for the definition of the **Heat-Transfer-Coefficient** function, enter the appropriate values. These profile input dialog boxes are used the same way as the profile input dialog boxes for temperature-dependent properties. See Defining Properties Using Temperature-Dependent Functions (p. 1590) to find out how to use them.

7.4.21.2.3.2. Constant Value

To define a constant heat transfer coefficient, follow these steps:

1. Choose **constant** in the **Heat-Transfer-Coefficient** drop-down list.

2. Enter the value for h in the **Heat-Transfer-Coefficient** field.

7.4.21.2.3.3. Example: Determining the Heat Transfer Coefficient Function

This example shows you how to determine the function for the heat transfer coefficient. Consider the simple two-dimensional duct flow of air through a water-cooled radiator, shown in Figure 7.80: A Simple Duct with a Radiator (p. 1492).

The data supplied in Table 7.2: Air-side Radiator Data (p. 1492) along with values for the air density (1.0 kg/ m^3) and specific heat (1000 J/kg-K) can be used to obtain the following values for the heat transfer coefficient h:

Velocity (m/s)	h (W/ m^2 -K)
5.0	2142.9
10.0	2903.2
15.0	3750.0

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The heat transfer coefficient obeys a second-order polynomial relationship (fit to the points in the table above) with the velocity, which is of the form

$$h = 1469.1 + 126.11v + 1.73v^2 \tag{7.146}$$

Note that the velocity v is assumed to be the absolute value of the velocity passing through the radiator.

7.4.21.2.4. Defining Discrete Phase Boundary Conditions for the Radiator

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the radiator. See Setting Boundary Conditions for the Discrete Phase (p. 2776) for details.

7.4.21.3. Postprocessing for Radiators

7.4.21.3.1. Reporting the Radiator Pressure Drop

You can use the Surface Integrals Dialog Box (p. 5271) to report the pressure drop across the radiator, as described in Surface Integration (p. 4116). There are two steps to this procedure:

1. Create a surface on each side of the radiator zone. Use the Transform Surface Dialog Box (p. 5575) (as described in Transforming Surfaces (p. 3823)) to translate the radiator zone slightly upstream and slightly downstream to create two new surfaces.

2. In the **Surface Integrals** dialog box, report the average **Static Pressure** just upstream and just downstream of the radiator. You can then calculate the pressure drop across the radiator.

To check this value against the expected value based on Equation 7.137 (p. 1488), you can use the **Surface Integrals** dialog box to report the average normal velocity through the radiator. (If the radiator is not aligned with the x, y, or z axis, you will need to use the Custom Field Function Calculator Dialog Box (p. 5372) to generate a function for the velocity normal to the radiator.) Once you have the average normal velocity, you can use Equation 7.138 (p. 1488) to determine the loss coefficient and then Equation 7.137 (p. 1488) to calculate the expected pressure loss.

7.4.21.3.2. Reporting Heat Transfer in the Radiator

To determine the temperature rise across the radiator, follow the procedure outlined above for the pressure drop to generate surfaces upstream and downstream of the radiator. Then use the Surface Integrals Dialog Box (p. 5271) (as for the pressure drop report) to report the average **Static Temperature** on each surface. You can then calculate the temperature rise across the radiator.

7.4.21.3.3. Graphical Plots

Graphical reports of interest with radiators are as follows:

- Contours or profiles of **Static Pressure** and **Static Temperature**.
- XY plots of **Static Pressure** and **Static Temperature** vs position.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Displaying Graphics (p. 3847) explains how to generate graphical displays of data.

Important:

When generating these plots, be sure to turn off the display of node values so that you can see the different values on each side of the radiator. (If you display node values, the cell values on either side of the radiator will be averaged to obtain a node value, and you will not see, for example, the pressure loss across the radiator.)

7.4.22. Porous Jump Boundary Conditions

Porous jump conditions are used to model a thin "membrane" that has known velocity (pressure-drop) characteristics. It is essentially a 1D simplification of the porous media model available for cell zones. Examples of uses for the porous jump condition include modeling pressure drops through screens and filters, and modeling radiators when you are not concerned with heat transfer. This simpler model should be used whenever possible (instead of the full porous media model) because it is more robust and yields better convergence.

The thin porous medium has a finite thickness over which the pressure change is defined as a combination of Darcy's Law and an additional inertial loss term:

$$\Delta p = -\left(\frac{\mu}{\alpha} v + C_2 \frac{1}{2} \rho v^2\right) \Delta m \tag{7.147}$$

where μ is the laminar fluid viscosity, α is the permeability of the medium, C_2 is the pressure-jump coefficient, v is the velocity normal to the porous face, and Δm is the thickness of the medium. Appropriate values for α and C_2 can be calculated using the techniques described in User Inputs for Porous Media (p. 1320).

In a coupled analysis involving Fluent and System Coupling, data can be transferred to and from the porous jump boundary. For more about System Coupling, see Performing System Coupling Simulations Using Fluent (p. 4595). For more information about the data transferred, see Force transferred to System Coupling from a Porous Jump Boundary (p. 4604).

Note:

- The porous jump boundary condition considers only the momentum resistance. Diffusion processes are not considered.
- In some cases, the pressure-based coupled solver with porous jump boundary conditions may suffer from convergence issues that do not respond to changes in the coupled solver settings. This behavior depends on the specific flow configuration and porous jump boundary condition values. If convergence instability is observed using the coupled pressure-based solver, it is recommended that you change the pressure-velocity coupling to one of the segregated schemes.

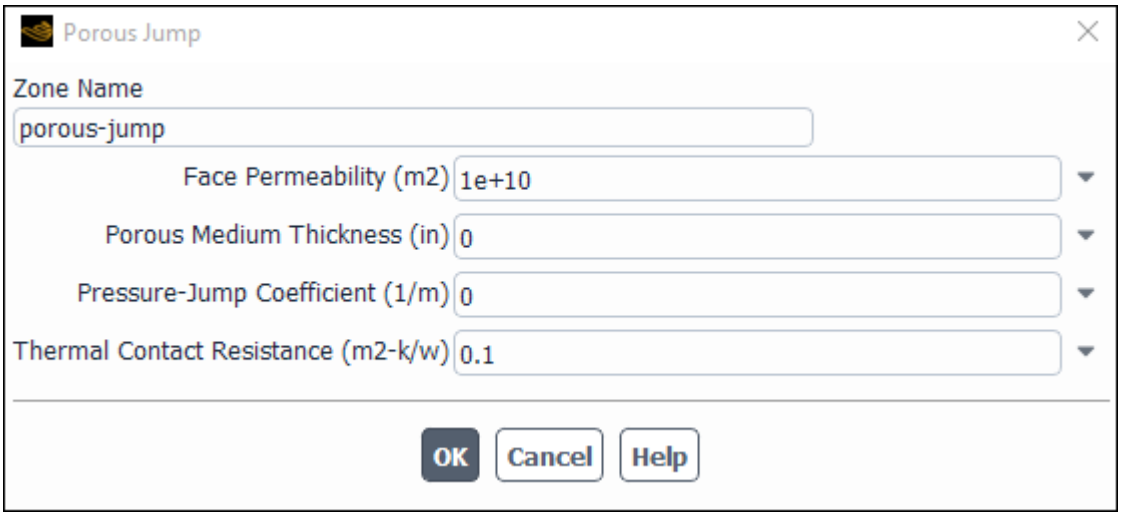
7.4.22.1. User Inputs for the Porous Jump Model

Once the porous jump zone has been identified (in the **Boundary Conditions** task page), you will set all modeling inputs for the porous jump in the Porous Jump Dialog Box (p. 4988) (Figure 7.81: The

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Porous Jump Dialog Box (p. 1496)), which is opened from the Boundary Conditions Task Page (p. 4937) (as described in Setting Cell Zone and Boundary Conditions (p. 1281)).

Figure 7.81: The Porous Jump Dialog Box



The inputs required for the porous jump model are as follows:

1. Identify the porous-jump zone.
2. Set the **Face Permeability** of the medium (α in Equation 7.147 (p. 1495)).
3. Set the **Porous Medium Thickness** (Δm).
4. Set the **Pressure-Jump Coefficient** (C_2).

> **Note:**
>
> The unit for the pressure-jump coefficient (C2) is the inverse of length. Should you want to define different units, you can do so by opening the **Units** dialog box and selecting **length-inverse** from the **Quantities** list.

5. Set the **Thermal Contact Resistance**.
6. Define the discrete phase boundary condition for the porous jump (for discrete phase calculations).
7. If you have enabled the solar load model, define the **Solar Boundary Conditions** for the porous jump. These settings allow you to define the boundary such that it acts as a semi-transparent surface (with respect to the solar radiation calculation only), and therefore allows a portion of the solar radiation to pass through it. See Solar Ray Tracing (p. 2225) for details.

7.4.22.1.1. Identifying the Porous Jump Zone

Since the porous jump model is a 1D simplification of the porous media model, the porous-jump zone must be modeled as the interface between cells, rather than a cell zone. Therefore the porous-jump zone is a type of internal face zone (where the faces are line segments in 2D or tri-

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

angles/quadrilaterals in 3D). If the porous-jump zone is not identified as such by default when you read in the mesh (that is, if it is identified as another type of internal face zone), you can right-click the zone in the tree and use the **Type** sub-menu to change it to a **porous-jump** zone (for more details, see Changing Cell and Boundary Zone Types (p. 1279)).

After the zone has been changed to a porous jump, you can open the Porous Jump Dialog Box (p. 4988) (as described in Setting Cell Zone and Boundary Conditions (p. 1281)) and specify the porous jump parameters listed above.

7.4.22.1.2. Defining Discrete Phase Boundary Conditions for the Porous Jump

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the porous jump. See Setting Boundary Conditions for the Discrete Phase (p. 2776) for details.

7.4.22.2. Postprocessing for the Porous Jump

Postprocessing suggestions for a problem that includes a porous jump are the same as for porous media problems. See Postprocessing for Porous Media (p. 1349).

7.5. Editing Multiple Boundary Conditions at Once

You can edit multiple related boundaries (zones of the same type) at the same time to simplify the setup process for Ansys Fluent cases.

Using the **Multi Edit** dialog box, you can edit or apply selected settings only, to a set of boundaries without opening multiple different dialog boxes. The dialog box includes colored icons to indicate which setting(s) will be applied on the selected zones.

To access the **Multi Edit** dialog box:

1. Select the boundaries that you want to edit in the Outline View tree. *You can select multiple-boundaries by holding **Ctrl** while you left-click.*

   Alternatively, you can select the boundaries that you want to edit in the **Adjacent Face Zones** list of the Adjacency Dialog Box (p. 5336).

   Note:

   One-sided (or external) walls cannot be selected together with coupled (or internal) walls for multi-editing.

2. Right-click the highlighted boundaries and click **Multi Edit...**.

   While Figure 7.82: The Multi Edit Wall Settings Dialog Box (p. 1498) is only for performing a multi-edit of velocity inlets, the multi-edit functionality is available for the following boundary types:

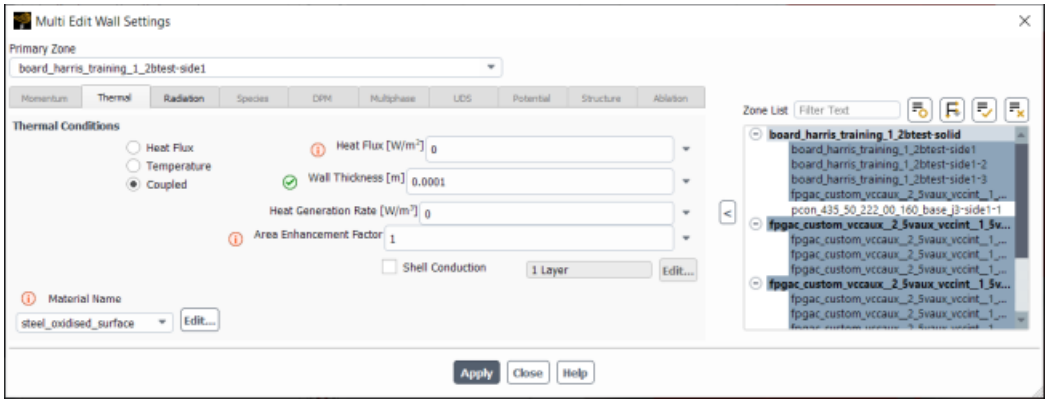
   - exhaust fans
   - inlet vents

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- intake fans
- mass flow inlets
- mass flow outlets
- outflows
- outlet vents
- pressure far fields
- pressure inlets
- pressure outlets
- velocity inlets
- walls

The setup for the multi-edit versions of these dialog boxes is the same as their non-multi-edit counterparts. The multi-edit functionality described in this section is consistent for all of the types.

Figure 7.82: The Multi Edit Wall Settings Dialog Box



The colored icons within the **Multi Edit** dialog box indicate the states of the various fields:

- ⓘ indicates that the value of this setting varies between the selected boundaries.
- ✓ indicates that the displayed value will be applied to the selected boundaries when you click **Apply**.

  *You can click an icon to change its state, which would be useful if you modify multiple settings, then realize you made a mistake on one of them. To rectify the mistake, you can simply click ✓ to remove it, indicating that the setting will not be applied when you click **Apply**.*

Note:

For any value entry or selection that results in changes to other fields, do not rely on just reverting the "primary field" (by clicking the ✓ icon) to revert the other affected fields.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If a field has a green check mark ( ) next to it, assume that the shown value will be applied on **Apply**, regardless of if you revert the initial change that led to the other field changes.

3. **Primary Zone** lists the zone that is used as the "baseline", to which all of the other selected zones are compared. You can change which zone is selected as the primary zone by:

   - Select a new primary zone from the **Primary Zone** drop-down list.
   - Deselect all of the zones in the **Zone** list and select the desired primary zone first when re-selecting which zones to use for the multi-edit functionality.

4. (Multiphase simulations only) Use the **Phase** drop-down list to specify boundary settings for each phase. *Note that you must click **Apply** before selecting a new phase for the settings to be applied.*

5. The **Zone List** shows the selected boundaries where the fields denoted with the icon will be applied.

   You can change which boundaries are highlighted in the **Zone List**, allowing you to selectively apply settings to a subset of the boundaries in the list. The settings are applied to the selected (highlighted) zones when you click **Apply**.

   You can sort the **Zone List** based on adjacency or by name by clicking and selecting **Adjacency** or **Name**.

Note:

Changes made to boundary settings using a "multi-edit" dialog box are also printed in the console and transcript (if one is being written).

7.6. Transient Cell Zone and Boundary Conditions

There are three ways you can specify transient cell zone and boundary conditions:

- transient profile with a format similar to the standard profiles described in Profiles (p. 1540)
- transient profile in a tabular format
- transient profile in comma separated values (CSV) format, as described in CSV Profiles (p. 1543).

Important:

For both methods, the cell zone or boundary condition will vary only in time; it must be spatially uniform. However, if the in-cylinder model is activated (In-Cylinder Settings (p. 1836)), then you have the option to use the crank angle instead of time. Crank angles can be included in transient tables as well as transient profiles, in a similar fashion to time. Examples of transient profiles and transient tables in crank angle can be found in the sections that follow.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For information about boundary profiles, refer to Reading and Writing Profile Files (p. 940).

7.6.1. Standard Transient Profiles

The format of the standard transient profile file (based on the profiles described in Profiles (p. 1540)) is

```
((profile-name transient n periodic?)
(field_name-1 a1 a2 a3 .... an)
(field_name-2 b1 b2 b3 .... bn)
.
.
.
.
(field_name-r r1 r2 r3 .... rn))
```

The profile name as well as the field names have to be shorter than 64 characters. One of the `field_name` s should be used for the `time` field, and the `time` field section *must* be in ascending order. n is the number of entries per field. The `periodic?` entry indicates whether or not the profile is time-periodic. Set it to `1` for a time-periodic profile, or `0` if the profile is not time-periodic.

An example is shown below:

```
((sampleprofile transient 3 0)
(time
1
2
3
)
(u
10
20
30
)
)
```

This example demonstrates the use of crank angle in a transient profile

```
((example transient 3 1)
(angle
0.000000e+00 1.800000e+02 3.600000e+02)
(temperature
3.000000e+02 5.000000e+02 3.000000e+02)
)
```

Important:

All quantities, including coordinate values, must be specified in SI units because Ansys Fluent does not perform unit conversion when reading profile files. Also, profile names must have all lowercase letters (for example, `name`). Uppercase letters in profile names are not acceptable.

You can read this file into Ansys Fluent using the Profiles Dialog Box (p. 4929) or the **File/Read/Profile...** ribbon tab item.

Setup → **Cell Zone Conditions** → **Profiles...**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setup → **Boundary Conditions** → **Profiles...**

File → **Read** → **Profile...**

See Using Profiles (p. 1546) for details.

7.6.2. Tabular Transient Profiles

The format of the tabular transient profile file is

```
profile-name n_field n_data periodic?
field-name-1 field-name-2 field-name-3 .... field-name-n_field
v-1-1  v-2-1... ... ... ... v-n_field-1
v-1-2  v-2-2... ... ... ... v-n_field-2
.
.
.
.
.
v-1-n_data v-2-n_data ... ... ... ... v-n_field-n_data
```

The first field name (for example `field-name-1`) should be used for the `time` field, and the `time` field section, which represents the flow time, *must* be in ascending order. The `periodic?` entry indicates whether or not the profile is time-periodic. Set it to `1` for a time-periodic profile, or `0` if the profile is not time-periodic.

An example is shown below:

```
sampletabprofile 2 3 0
time u
1 10
2 20
3 30
```

This file defines the same transient profile as the standard profile example above.

If the periodicity is set to `1`, then `n_data` must be the number that closes one period.

An example is shown below:

```
periodtabprofile 2 4 1
time u
0 10
1 20
2 30
3 10
```

The following example uses crank angle instead of time:

```
example 2 3 1
angle temperature
0  300
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
180 500
360 300
```

Important:

- All quantities, including coordinate values, must be specified in SI units because Ansys Fluent does not perform unit conversion when reading profile files. Also, profile names must have all lowercase letters (for example, `name`). Uppercase letters in profile names are not acceptable. When choosing the field names, spaces or parentheses should not be included.
- Some file formats may not be read into Fluent correctly (for example, UCS-2). If your file is not read correctly, copy the contents into a text editor (Notepad++/VIM/Notepad) and save it. This updated version of your profile is now readable in Fluent.

You can read this file into Ansys Fluent using the `read-transient-table` text command.

`file` → `read-transient-table`

After reading the table into Ansys Fluent, the profile will be listed in the Profiles Dialog Box (p. 4929) and can be used in the same way as a boundary profile. See Using Profiles (p. 1546) for details.

7.6.3. Profiles for Moving and Deforming Meshes

You can use profiles to specify position, velocity, and angular velocity. There are two different valid profile formats for moving and deforming mesh cases.

```
profile-name n_field n_data periodic?
field-name-1 field-name-2 field-name-3 .... field-name-n_field
v-1-1  v-2-1... ... ... ... v-n_field-1
v-1-2  v-2-2... ... ... ... v-n_field-2
.
.
.
.
.
v-1-n_data v-2-n_data ... ... ... ... v-n_field-n_data
```

and

```
((profile-name transient n periodic?)
(field_name-1 a1 a2 a3 .... an)
(field_name-2 b1 b2 b3 .... bn)
.
.
.
.
(field_name-r r1 r2 r3 .... rn))
```

You must use the appropriate variable nomenclature when writing your profile so that Fluent can properly interpret your inputs. For position, use `x`, `y`, and `z`. For specifying velocity, use `v_x`, `v_y`, and `v_z`. Similarly, for angular velocity, use `omega_x`, `omega_y`, and `omega_z`.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.7. Boundary Acoustic Wave Models

The standard boundary conditions, when imposed on the boundaries of an artificially truncated domain, result in the reflection of the outgoing pressure waves. As a consequence, the interior domain will contain spurious wave reflections. Many applications require precise control of the wave reflections from the domain boundaries to obtain accurate flow solutions. Ansys Fluent offers several boundary wave models that can be used to at the domain boundaries to control these spurious wave reflections.

The following boundary acoustic wave models are available:

- turbo-specific non-reflecting boundary condition (NRBC) (density-based solver only)
- general NRBC (pressure-based and density-based solvers)
- impedance boundary condition (pressure-based solver only)
- transparent flow forcing (pressure-based solver only)

In the density-based solver, the NRBC models are available for flows using the compressible ideal-gas law.

In the pressure-based solver, the general NRBC, impedance, and transient flow forcing models available for transient simulations of compressible flows (including the ideal-gas law, real gas law, species transport, and compressible mixture models).

Information about the available boundary acoustic wave models is provided in the following sections.

7.7.1. Turbo-Specific Non-Reflecting Boundary Conditions
7.7.2. General Non-Reflecting Boundary Conditions
7.7.3. Impedance Boundary Conditions
7.7.4. Transparent Flow Forcing Boundary Conditions

Note:

An alternative to the boundary acoustic wave models is to define sponge layers at boundary zones. Such sponge layers are based on the density, and are only available in a transient simulation for a compressible flow with the pressure-based solver. For details, see Sponge Layers (p. 2665).

7.7.1. Turbo-Specific Non-Reflecting Boundary Conditions

Information about turbo-specific NRBCs is provided in the following sections.

7.7.1.1. Overview
7.7.1.2. Limitations
7.7.1.3. Theory
7.7.1.4. Using Turbo-Specific Non-Reflecting Boundary Conditions

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.7.1.1. Overview

The standard pressure boundary conditions for compressible flow fix specific flow variables at the boundary (for example, static pressure at an outlet boundary). As a result, pressure waves incident on the boundary will reflect in an unphysical manner, leading to local errors. The effects are more pronounced for internal flow problems where boundaries are usually close to geometry inside the domain, such as compressor or turbine blade rows.

The turbo-specific non-reflecting boundary conditions permit waves to "pass" through the boundaries without spurious reflections. The method used in Ansys Fluent is based on the Fourier transformation of solution variables at the non-reflecting boundary [50] (p. 5657). Similar implementations have been investigated by other authors [98] (p. 5660) [130] (p. 5662). The solution is rearranged as a sum of terms corresponding to different frequencies, and their contributions are calculated independently. While the method was originally designed for axial turbomachinery, it has been extended for use with radial turbomachinery.

7.7.1.2. Limitations

Note the following limitations of turbo-specific NRBCs:

- They are available only with the density-based solver (explicit or implicit).
- The current implementation applies to steady compressible flows, with the density calculated using the ideal gas law.
- Inlet and outlet boundary conditions must be pressure inlets and outlets only.

  Important:

  Note that the pressure inlet boundaries must be set to the cylindrical coordinate flow specification method when turbo-specific NRBCs are used.

- Quad-mapped (structured) surface meshes must be used for inflow and outflow boundaries in a 3D geometry (that is, triangular or quad-paved surface meshes are not allowed). See Figure 7.83: Mesh and Prescribed Boundary Conditions in a 3D Axial Flow Problem (p. 1505) and Figure 7.84: Mesh and Prescribed Boundary Conditions in a 3D Radial Flow Problem (p. 1506) for examples.

  Important:

  Note that you may use unstructured meshes in 2D geometries (Figure 7.85: Mesh and Prescribed Boundary Conditions in a 2D Case (p. 1507)), and an unstructured mesh may be used away from the inlet and outlet boundaries in 3D geometries.

- The turbo-specific NRBC [50] (p. 5657) has been extended for use on 3D geometries [130] (p. 5662) by decoupling the tangential flow variations from the radial variations. This approximation works best for geometries with a blade pitch that is small compared to the radius of the geometry.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Reverse flow on the inflow and outflow boundaries are not allowed. If strong reverse flow is present, then you should consider using the General NRBCs instead.
- NRBCs are not compatible with species transport models. They are mainly used to solve ideal-gas single-species flow.

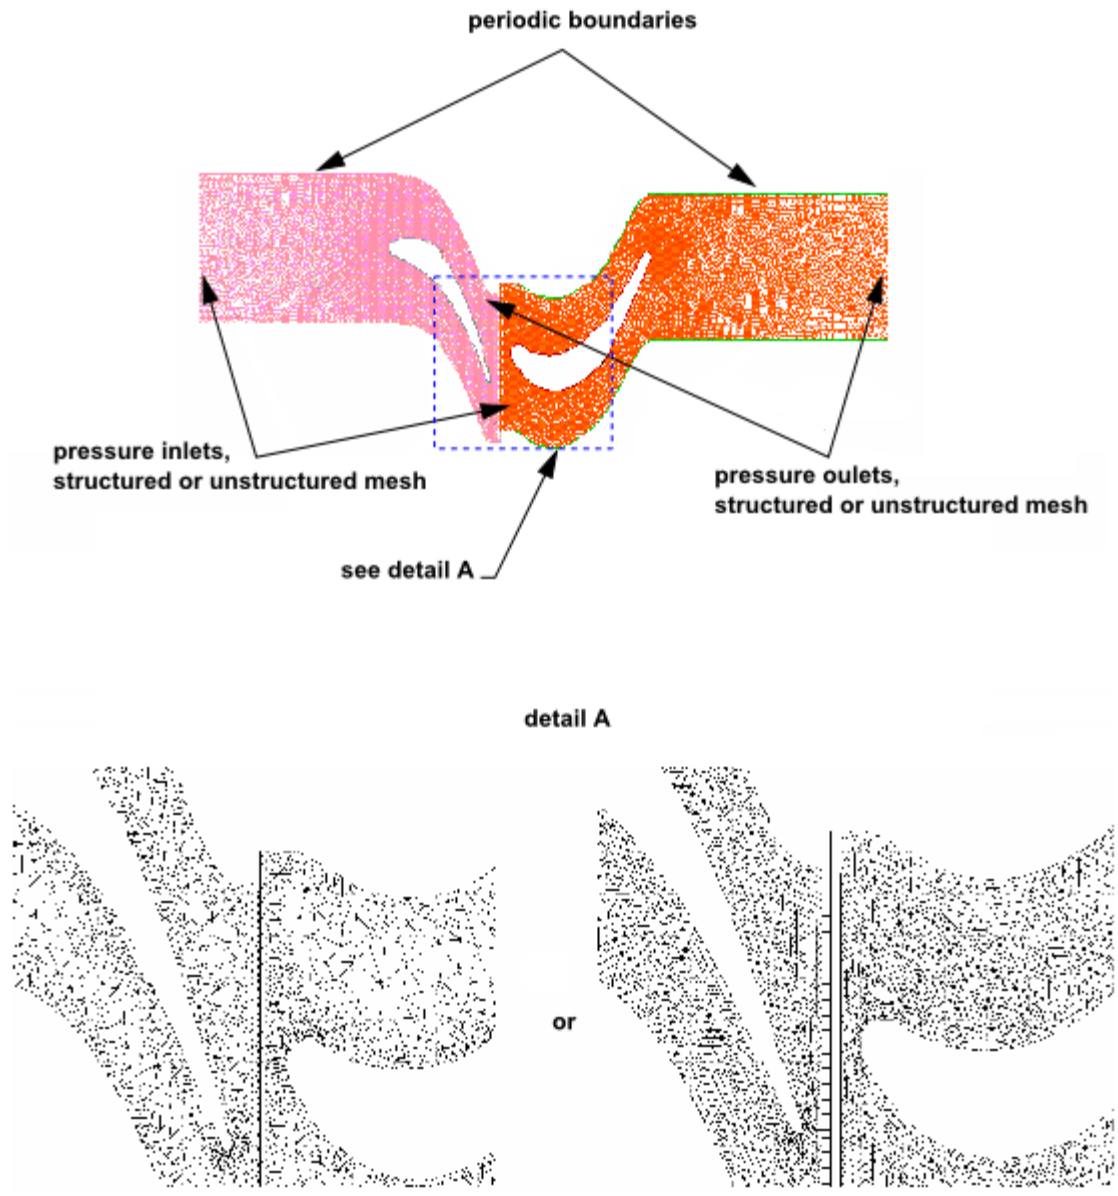
Figure 7.85: Mesh and Prescribed Boundary Conditions in a 2D Case



7.7.1.3. Theory

Turbo-specific NRBCs are based on Fourier decomposition of solutions to the linearized Euler equations. The solution at the inlet and outlet boundaries is circumferentially decomposed into Fourier modes, with the 0th mode representing the average boundary value (which is to be imposed as a user input), and higher harmonics that are modified to eliminate reflections [130] (p. 5662).

7.7.1.3.1. Equations in Characteristic Variable Form

In order to treat individual waves, the linearized Euler equations are transformed to characteristic variable (C_i) form. If we first consider the 1D form of the linearized Euler equations, it can be shown that the characteristic variables C_i are related to the solution variables as follows:

$$\tilde{Q} = T^{-1} C \tag{7.148}$$

where

$$\tilde{Q}=\begin{Bmatrix}\tilde{\rho}\\ \tilde{u}_a\\ \tilde{u}_t\\ \tilde{u}_r\\ \tilde{p}\end{Bmatrix},T^{-1}=\begin{bmatrix}-\frac{1}{\overline{a}^2} & 0 & 0 & \frac{1}{2\overline{a}^2} & \frac{1}{2\overline{a}^2}\\ 0 & 0 & 0 & \frac{1}{2\overline{\rho}\,\overline{a}} & \frac{1}{2\overline{\rho}\,\overline{a}}\\ 0 & \frac{1}{\overline{\rho}\,\overline{a}} & 0 & 0 & 0\\ 0 & 0 & \frac{1}{\overline{\rho}\,\overline{a}} & 0 & 0\\ 0 & 0 & 0 & \frac{1}{2} & \frac{1}{2}\end{bmatrix},C=\begin{Bmatrix}C_1\\ C_2\\ C_3\\ C_4\\ C_5\end{Bmatrix} \tag{7.149}$$

where $\overline{a}$ is the average acoustic speed along a boundary zone, $\tilde{\rho}$, $\tilde{u}_a$, $\tilde{u}_t$, $\tilde{u}_r$, and $\tilde{p}$ represent perturbations from a uniform condition (for example, $\tilde{\rho}=\rho-\overline{\rho}$,$\tilde{p}=p-\overline{p}$, and so on).

Note that the analysis is performed using the cylindrical coordinate system. All overlined (averaged) flow field variables (for example, $\overline{\rho}$, $\overline{a}$) are intended to be averaged along the pitchwise direction.

In quasi-3D approaches [50] (p. 5657) [98] (p. 5660) [130] (p. 5662), a procedure is developed to determine the changes in the characteristic variables, denoted by δC_i, at the boundaries such that waves will not reflect. These changes in characteristic variables are determined as follows:

$$\delta C=T\,\delta Q \tag{7.150}$$

where

$$\delta C=\begin{Bmatrix}\delta C_1\\ \delta C_2\\ \delta C_3\\ \delta C_4\\ \delta C_5\end{Bmatrix},T=\begin{bmatrix}-\overline{a}^2 & 0 & 0 & 0 & 1\\ 0 & 0 & \overline{\rho}\,\overline{a} & 0 & 0\\ 0 & 0 & 0 & \overline{\rho}\,\overline{a} & 0\\ 0 & \overline{\rho}\,\overline{a} & 0 & 0 & 1\\ 0 & -\overline{\rho}\,\overline{a} & 0 & 0 & 1\end{bmatrix},\delta Q=\begin{Bmatrix}\delta\rho\\ \delta u_a\\ \delta u_t\\ \delta u_r\\ \delta p\end{Bmatrix} \tag{7.151}$$

The changes to the outgoing characteristics — one characteristic for subsonic inflow (δC_5), and four characteristics for subsonic outflow (δC_1, δC_2, δC_3, δC_4) — are determined from extrapolation of the flow field variables using Equation 7.150 (p. 1508).

The changes in the incoming characteristics — four characteristics for subsonic inflow (δC_1, δC_2, δC_3, δC_4), and one characteristic for subsonic outflow (δC_5) — are split into two components: average change along the boundary ($\delta\overline{C}_i$), and local changes in the characteristic variable due to harmonic variation along the boundary (δC_{iL}). The incoming characteristics are therefore given by

$$\delta C_{i_j}=\delta C_{iold_j}+\sigma\left(\delta C_{inew_j}-\delta C_{iold_j}\right) \tag{7.152}$$

$$\delta C_{inew_j}=\left(\delta\overline{C}_i+\delta C_{iL_j}\right) \tag{7.153}$$

where $i=1,2,3,4$ on the inlet boundary or $i=5$ on the outlet boundary, and $j=1,\ldots,N$ is the grid index in the pitchwise direction including the periodic point once. The under-relaxation factor σ has a default value of 0.75. Note that this method assumes a periodic solution in the pitchwise direction.

The flow is decomposed into mean and circumferential components using Fourier decomposition. The 0th Fourier mode corresponds to the average circumferential solution, and is treated according

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

to the standard 1D characteristic theory. The remaining parts of the solution are described by a sum of harmonics, and treated as 2D non-reflecting boundary conditions [50] (p. 5657).

7.7.1.3.2. Inlet Boundary

For subsonic inflow, there is one outgoing characteristic (δC_5) determined from Equation 7.150 (p. 1508), and four incoming characteristics (δC_1, δC_2, δC_3, δC_4) calculated using Equation 7.152 (p. 1508). The average changes in the incoming characteristics are computed from the requirement that the entropy (s), radial and tangential flow angles (α_r and α_t), and stagnation enthalpy (h_0) are specified. Note that in Ansys Fluent you can specify p_0 and T_0 at the inlet, from which s_{in} and $h_{0_{in}}$ are easily obtained. This is equivalent to forcing the following four residuals to be zero:

$$R_1 = \overline{\rho}\left(\overline{s} - s_{in}\right) \tag{7.154}$$

$$R_2 = \overline{\rho}\,\overline{a}\left(\overline{u}_t - \overline{u}_a \tan\alpha_t\right) \tag{7.155}$$

$$R_3 = \overline{\rho}\,\overline{a}\left(\overline{u}_r - \overline{u}_a \tan\alpha_r\right) \tag{7.156}$$

$$R_4 = \overline{\rho}\left(\overline{h}_0 - h_{0_{in}}\right) \tag{7.157}$$

where

$$s_{in} = \gamma \ln\left(T_{0_{in}}\right) - (\gamma - 1)\ln\left(p_{0_{in}}\right) \tag{7.158}$$

$$h_{0_{in}} = c_p T_{0_{in}} \tag{7.159}$$

The average characteristic is then obtained from residual linearization as follows (see also Figure 7.86: Prescribed Inlet Angles (p. 1510)

$$\begin{Bmatrix} \delta\overline{C}_1 \\ \delta\overline{C}_2 \\ \delta\overline{C}_3 \\ \delta\overline{C}_4 \end{Bmatrix} = \begin{bmatrix} -1 & 0 & 0 & 0 \\ \frac{\tan\alpha_t}{(1-\gamma)M} & \frac{M_1}{M} & \frac{-M_t}{M}\tan\alpha_t & \frac{\tan\alpha_t}{M} \\ \frac{\tan\alpha_r}{(\gamma-1)M} & \frac{M_t}{M}\tan\alpha_t & \frac{M_2}{M} & \frac{-\tan\alpha_r}{M} \\ \frac{2}{(\gamma-1)M} & 2\frac{M_t}{M} & 2\frac{M_r}{M} & \frac{-2}{M} \end{bmatrix} \begin{Bmatrix} R_1 \\ R_2 \\ R_3 \\ R_4 \end{Bmatrix} \tag{7.160}$$

where

$$M_a = \frac{\overline{u}_a}{\overline{a}} \tag{7.161}$$

$$M_t = \frac{\overline{u}_t}{\overline{a}} \tag{7.162}$$

$$M_r = \frac{\overline{u}_r}{\overline{a}} \tag{7.163}$$

and

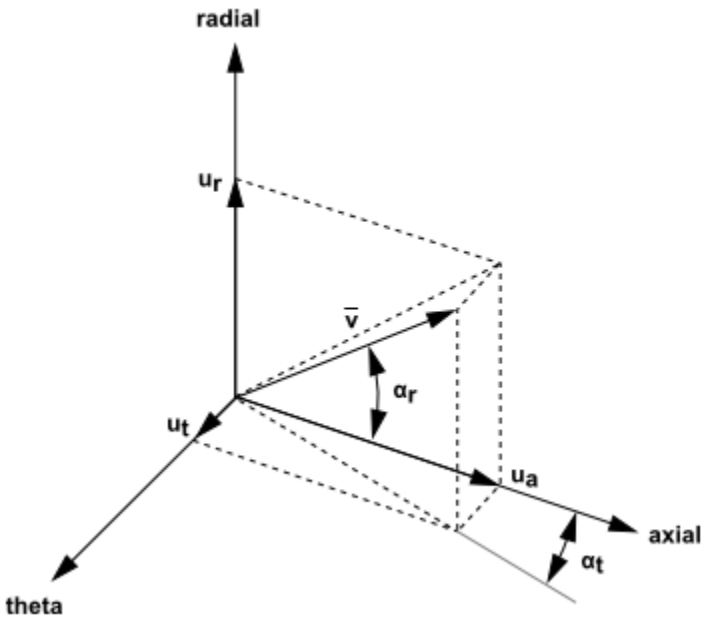
$$M = 1 + M_a - M_t \tan\alpha_t + M_r \tan\alpha_r \tag{7.164}$$

$$M_1 = -1 - M_a - M_r \tan\alpha_r \tag{7.165}$$

$$M_2 = -1 - M_a - M_t \tan\alpha_t \tag{7.166}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.86: Prescribed Inlet Angles



where

$$|v| = \sqrt{u_t^2 + u_r^2 + u_a^2} \tag{7.167}$$

$$e_t = \frac{u_t}{|v|} \tag{7.168}$$

$$e_r = \frac{u_r}{|v|} \tag{7.169}$$

$$e_a = \frac{u_a}{|v|} \tag{7.170}$$

$$\tan\alpha_t = \frac{e_t}{e_a} \tag{7.171}$$

$$\tan\alpha_r = \frac{e_r}{e_a} \tag{7.172}$$

To address the local characteristic changes at each j grid point along the inflow boundary, the following relations are developed [50] (p. 5657) [130] (p. 5662):

$$\begin{aligned}
\delta C_{1L_j} &= \overline{p}\left(s_j - \overline{s}\right) \\
\delta C_{2L_j} &= C'_{2_j} - \overline{\rho a}\left(u_{t_j} - \overline{u}_t\right) \\
\delta C_{3L_j} &= -\overline{\rho a}\left(u_{r_j} - \overline{u}_r\right) \\
\delta C_{4L_j} &= \frac{-2}{(1+M_{a_j})}\left(\frac{1}{\gamma-1}\delta C_{1L_j} + M_{t_j}\delta C_{2L_j} + M_{r_j}\delta C_{3L_j} + \overline{\rho}\left(h_{0_j} - \overline{h}_0\right)\right)
\end{aligned} \tag{7.173}$$

Note that the relation for the first and fourth local characteristics force the local entropy and stagnation enthalpy to match their average steady-state values.

The characteristic variable C'_{2_j} is computed from the inverse discrete Fourier transform of the second characteristic. The discrete Fourier transform of the second characteristic in turn is related to the discrete Fourier transform of the fifth characteristic. Hence, the characteristic variable C'_{2_j} is computed along the pitch as follows:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$C_{2_j}^{'}=2\Re\left(\sum_{n=1}^{\frac{N}{2}-1}\hat{C}_{2_n}\exp\left(i2\pi n\frac{\theta_j-\theta_1}{\theta_N-\theta_1}\right)\right) \tag{7.174}$$

The Fourier coefficients $C_{2_n}^{'}$ are related to a set of equidistant distributed characteristic variables $C_{5_j}^{*}$ by the following [98] (p. 5660):

$$\hat{C}_{2_n}=\begin{cases}-\frac{\overline{u}_t+B}{N(\overline{a}+\overline{u}_a)}\sum_{j=1}^{N}C_{5_j}^{*}\exp\left(-i2\pi\frac{jn}{N}\right) & \beta>0\\ -\frac{\overline{u}_t+B}{\overline{a}+\overline{u}_a}C_{5_j} & \beta<0\end{cases} \tag{7.175}$$

where

$$B=\begin{cases}i\sqrt{\beta} & \beta>0\\ -sign(\overline{u}_t)\sqrt{|\beta|} & \beta<0\end{cases} \tag{7.176}$$

and

$$\beta=\overline{a}^2-\overline{u}_a^2-\overline{u}_t^2 \tag{7.177}$$

The set of equidistributed characteristic variables $C_{5_j}^{*}$ is computed from arbitrary distributed C_{5_j} by using a cubic spline for interpolation, where

$$C_{5_j}=-\overline{\rho}\,\overline{a}\left(u_{a_j}-\overline{u}_a\right)+\left(p_j-\overline{p}\right) \tag{7.178}$$

For supersonic inflow the user-prescribed static pressure ($p_{s_{in}}$) along with total pressure ($p_{0_{in}}$) and total temperature ($T_{0_{in}}$) are sufficient for determining the flow condition at the inlet.

7.7.1.3.3. Outlet Boundary

For subsonic outflow, there are four outgoing characteristics (δC_1, δC_2, δC_3, and δC_4) calculated using Equation 7.150 (p. 1508), and one incoming characteristic (δC_5) determined from Equation 7.152 (p. 1508). The average change in the incoming fifth characteristic is given by

$$\delta\overline{C}_5=-2\left(\overline{p}-p_{out}\right) \tag{7.179}$$

where $\overline{p}$ is the current averaged pressure at the exit plane and p_{out} is the desirable average exit pressure (this value is specified by you for single-blade calculations or obtained from the assigned profile for mixing-plane calculations). The local changes (δC_{5L_j}) are given by

$$\delta C_{5L_j}=C_{5_j}^{'}+\overline{\rho}\,\overline{a}\left(u_{a_j}-\overline{u}_a\right)-\left(p_j-\overline{p}\right) \tag{7.180}$$

The characteristic variable $C_{5_j}^{'}$ is computed along the pitch as follows:

$$C_{5_j}^{'}=2\Re\left(\sum_{n=1}^{\frac{N}{2}-1}\hat{C}_{5_n}\exp\left(i2\pi n\frac{\theta_j-\theta_1}{\theta_N-\theta_1}\right)\right) \tag{7.181}$$

The Fourier coefficients $\hat{C}_{5_n}$ are related to two sets of equidistantly distributed characteristic variables ($C_{2_j}^{*}$ and $C_{4_j}^{*}$, respectively) and given by the following [98] (p. 5660):

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\hat{C}_{5_n} = \begin{cases} \frac{A_2}{N}\sum_{j=1}^{N} C^*_{2_j} \exp\left(i2\pi\frac{jn}{N}\right) - \frac{A_4}{N}\sum_{j=1}^{N} C^*_{4_j} \exp\left(i2\pi\frac{jn}{N}\right) & \beta > 0 \\ A_2 C_{2_j} - A_4 C_{4_j} & \beta < 0 \end{cases} \tag{7.182}$$

where

$$A_2 = \frac{2\overline{u}_a}{B - \overline{u}_t} \tag{7.183}$$

$$A_4 = \frac{B + \overline{u}_t}{B - \overline{u}_t} \tag{7.184}$$

The two sets of equidistributed characteristic variables ($C^*_{2_j}$ and $C^*_{4_j}$) are computed from arbitrarily distributed C_{2_j} and C_{4_j} characteristics by using a cubic spline for interpolation, where

$$C_{2_j} = \overline{\rho}\,\overline{a}\left(u_{t_j} - \overline{u}_t\right) \tag{7.185}$$

$$C_{4_j} = \overline{\rho}\,\overline{a}\left(u_{a_j} - \overline{u}_a\right) + \left(p_j - \overline{p}\right) \tag{7.186}$$

For supersonic outflow all flow field variables are extrapolated from the interior.

7.7.1.3.4. Updated Flow Variables

Once the changes in the characteristics are determined on the inflow or outflow boundaries, the changes in the flow variables δQ can be obtained from Equation 7.150 (p. 1508). Therefore, the values of the flow variables at the boundary faces are as follows:

$$p_f = p_j + \delta p \tag{7.187}$$

$$u_{a_f} = u_{a_j} + \delta u_a \tag{7.188}$$

$$u_{t_f} = u_{t_j} + \delta u_t \tag{7.189}$$

$$u_{r_f} = u_{r_j} + \delta u_r \tag{7.190}$$

$$T_f = T_j + \delta T \tag{7.191}$$

7.7.1.4. Using Turbo-Specific Non-Reflecting Boundary Conditions

Important:

If you intend to use turbo-specific NRBCs in conjunction with the density-based implicit solver, it is recommended that you first converge the solution before turning on turbo-specific NRBCs, then converge it again with turbo-specific NRBCs turned on. If the solution is diverging, then you should lower the CFL number. These steps are necessary because only approximate flux Jacobians are used for the pressure-inlet and pressure-outlet boundaries when turbo-specific NRBCs are activated with the density-based implicit solver.

The procedure for using the turbo-specific NRBCs is as follows:

1. Turn on the turbo-specific NRBCs using the `non-reflecting-bc` text command:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

`define` → `boundary-conditions` → `non-reflecting-bc` → `turbo-specific-nrbc` → `enable?`

If you are not sure whether or not NRBCs are turned on, use the `show-status` text command.

2. Perform NRBC initialization using the `initialize` text command:

   `define` → `boundary-conditions` → `non-reflecting-bc` → `turbo-specific-nrbc` → `initialize`

   If the initialization is successful, a summary printout of the domain extent will be displayed. If the initialization is not successful, an error message will be displayed indicating the source of the problem. The initialization will set up the pressure-inlet and pressure-outlet boundaries for use with turbo-specific NRBCs.

   Important:

   Note that the pressure inlet boundaries must be set to the cylindrical coordinate flow specification method when turbo-specific NRBCs are used.

3. If necessary, modify the parameters in the `set/` submenu:

   `define` → `boundary-conditions` → `non-reflecting-bc` → `turbo-specific-nrbc` → `set`

   `under-relaxation`

   allows you to set the value of the under-relaxation factor σ in Equation 7.152 (p. 1508). The default value is 0.75.

   `discretization`

   allows you to set the discretization scheme. The default is to use higher-order reconstruction if available.

   `verbosity`

   allows you to control the amount of information printed to the console during an NRBC calculation.

   - `0`: silent
   - `1`: basic information (default)
   - `2`: detailed information (for debugging purposes only)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.7.1.4.1. Using the NRBCs with the Mixing-Plane Model

If you want to use the NRBCs with the mixing-plane model you must define the mixing plane interfaces as pressure-outlet and pressure-inlet zone type pairs.

Important:

Turbo-specific NRBCs should not be used with the mixing-plane model if reverse flow is present across the mixing-plane.

7.7.1.4.2. Using the NRBCs in Parallel Ansys Fluent

When the turbo-specific NRBCs are used in conjunction with the parallel solver, all cells in each boundary zone, where NRBCs will be applied, must be located or contained within a single partition. You can ensure this by manually partitioning the mesh (see Partitioning the Mesh Manually and Balancing the Load (p. 4285) for more information).

7.7.2. General Non-Reflecting Boundary Conditions

Information about general NRBCs is provided in the following sections.

7.7.2.1. Overview

7.7.2.2. Restrictions and Limitations

7.7.2.3. Theory

7.7.2.4. Using the General Non-Reflecting Boundary Condition

7.7.2.1. Overview

The general non-reflecting boundary conditions in Ansys Fluent are based on characteristic wave relations derived from the Euler equations. In the density-based solver, the non-reflecting boundary conditions are applied only on pressure-outlet boundary conditions. In the pressure-based solver they are applied on pressure-inlet, pressure-outlet, velocity-inlet and mass-flux boundary conditions. To obtain the primitive flow quantities (P, u, v, w, T), reformulated Euler equations are solved on the boundary of the domain in an algorithm similar to the flow equations applied to the interior of the domain.

Unlike the turbo-specific NRBC, the general NRBC method is not restricted by geometric constraints or mesh type. However, good cell skewness near the boundaries where the NRBCs can be applied for better convergence.

7.7.2.2. Restrictions and Limitations

Note the following restrictions and limitations on the general NRBCs:

- The general NRBC is not available if the target mass flow rate is activated in the pressure-outlet dialog box.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The general NRBC using the density-based solver is available only with compressible flow while using the ideal-gas law.

  Important:

  The general NRBC using the density-based solver should not be used with the wet steam or real gas models.

- The general NRBCs using the density-based solver are not compatible with species transport and mixture fraction transport models (for premixed and partially-premixed models). They are mainly used to solve ideal-gas single-component flow.
- The general NRBCs using the pressure-based solver are not compatible with steady-state cases or the Eulerian multiphase model. For VOF or mixture multiphase cases that involve compressible gases or compressible liquids, only pressure inlets and pressure outlets can enable the non-reflecting boundary condition option. Note that some small reflections may still occur from NRBC boundaries when secondary-phase volume fractions are nonzero at the boundaries.

7.7.2.3. Theory

General NRBCs are derived by first recasting the Euler equations in an orthogonal coordinate system (x_1, x_2, x_3) such that one of the coordinates, x_1, is normal to the boundary Figure 7.87: The Local Orthogonal Coordinate System onto which Euler Equations are Recasted for the General NRBC Method (p. 1516). The characteristic analysis [158] (p. 5664) [159] (p. 5664) is then used to modify terms corresponding to waves propagating in the x_1 normal direction. When doing so, a system of equations can be written to describe the wave propagation as follows:

$$\begin{aligned}
&\frac{\partial \rho}{\partial t} + d_1 + \frac{\partial m_2}{\partial x_2} + \frac{\partial m_3}{\partial x_3} = 0 \\
&\frac{\partial m_1}{\partial t} + U_1 d_1 + \rho d_3 + \frac{\partial (m_1 U_2)}{\partial x_2} + \frac{\partial (m_1 U_3)}{\partial x_3} = 0 \\
&\frac{\partial m_2}{\partial t} + U_2 d_1 + \rho d_4 + \frac{\partial (m_2 U_2)}{\partial x_2} + \frac{\partial (m_2 U_3)}{\partial x_3} + \frac{\partial P}{\partial x_2} = 0 \\
&\frac{\partial m_3}{\partial t} + U_3 d_1 + \rho d_5 + \frac{\partial (m_3 U_2)}{\partial x_2} + \frac{\partial (m_3 U_3)}{\partial x_3} + \frac{\partial P}{\partial x_3} = 0 \\
&\frac{\partial \rho E}{\partial t} + \frac{1}{2}|V|^2 d_1 + \frac{d_2}{(\gamma - 1)} + m_1 d_3 + m_2 d_4 + m_3 d_5 + \frac{\partial [(\rho E + P) U_2]}{\partial x_2} + \frac{\partial [(\rho E + P) U_3]}{\partial x_3} = 0
\end{aligned} \tag{7.192}$$

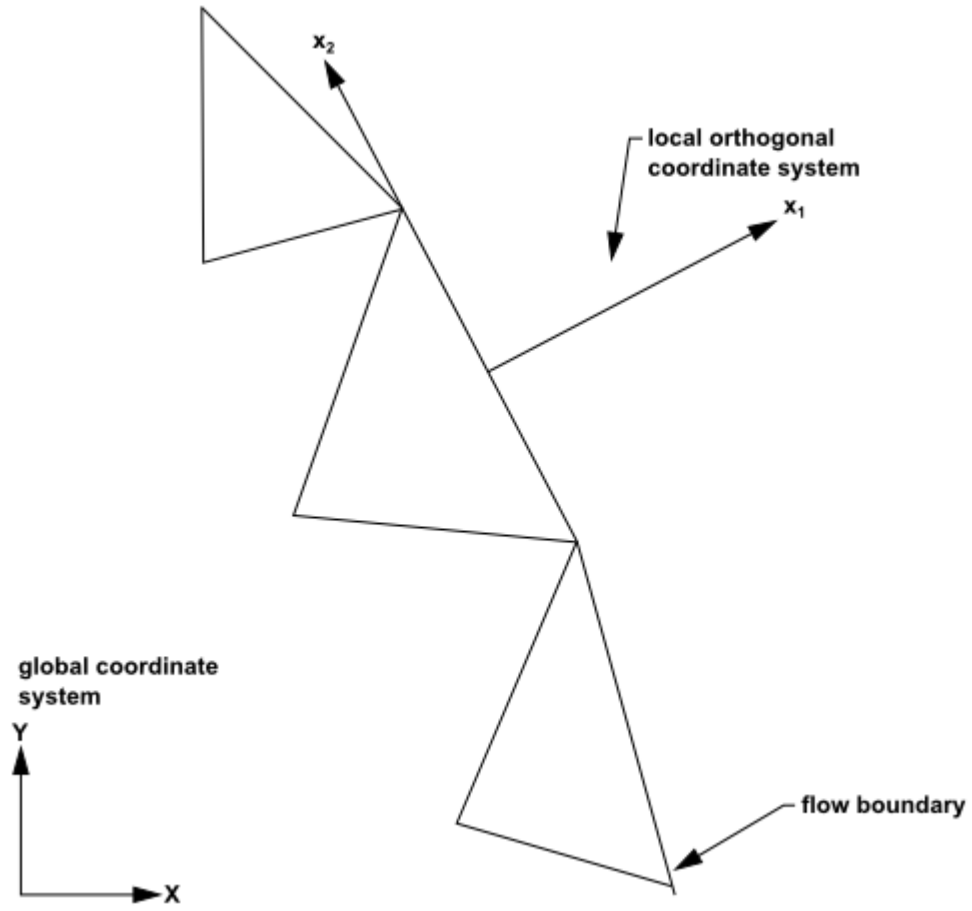
Where $m_1 = \rho U_1$, $m_2 = \rho U_2$ and $m_3 = \rho U_3$ and U_1, U_2 and U_3 are the velocity components in the coordinate system (x_1, x_2, x_3). The equations above are solved on non-reflecting boundaries, along with the interior governing flow equations, using similar time stepping algorithms to obtain the values of the primitive flow variables (P, u, v, w, T).

Important:

Note that a transformation between the local orthogonal coordinate system (x_1, x_2, x_3) and the global Cartesian system (X, Y, Z) must be defined on each face on the boundary to obtain the velocity components (u, v, w) in a global Cartesian system.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.87: The Local Orthogonal Coordinate System onto which Euler Equations are Recasted for the General NRBC Method



The d_i terms in the transformed Euler equations contain the outgoing and incoming characteristic wave amplitudes, L_i, and are defined as follows:

$$\begin{aligned} d_1 &= \frac{1}{c^2}\left[L_2 + \frac{1}{2}\left(L_5 + L_1\right)\right] \\ d_2 &= \frac{1}{2}\left(L_5 + L_1\right) \\ d_3 &= \frac{1}{2\rho c}\left(L_5 - L_1\right) \\ d_4 &= L_3 \\ d_5 &= L_4 \end{aligned} \tag{7.193}$$

From characteristic analyses, the wave amplitudes, L_i, are given by:

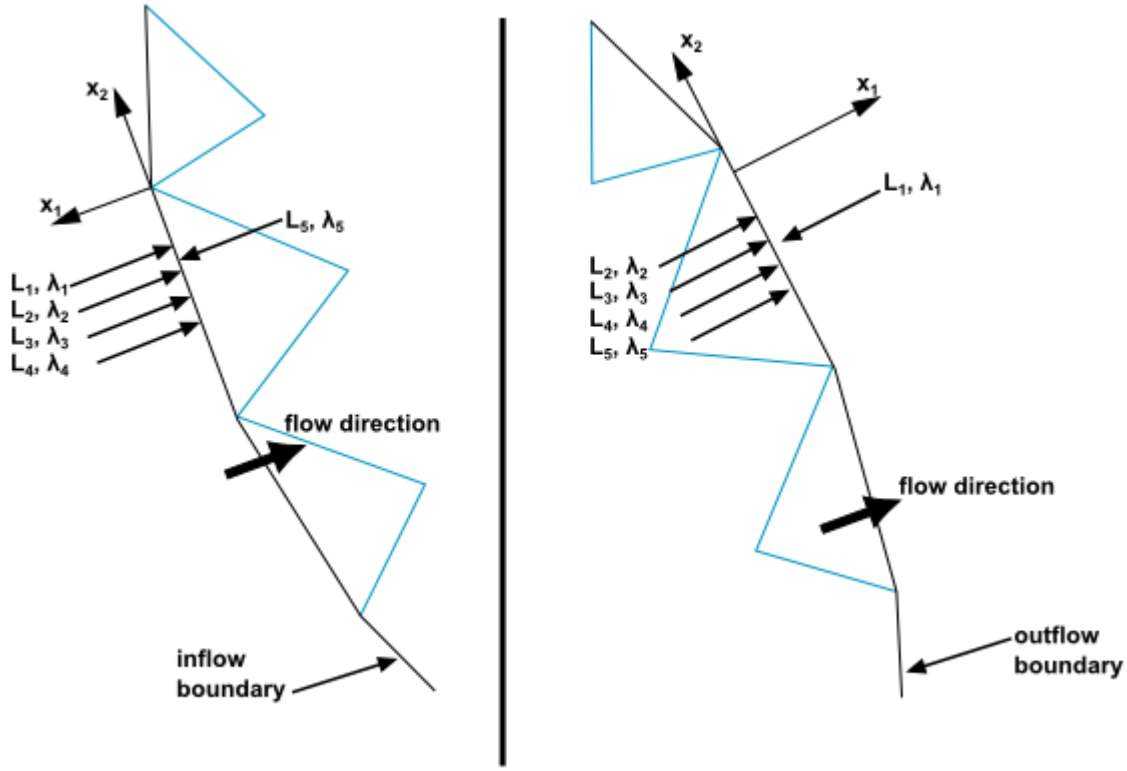
$$\begin{aligned} L_1 &= \lambda_1\left(\frac{\partial P}{\partial x_1} - \rho c \frac{\partial U_1}{\partial x_1}\right) \\ L_2 &= \lambda_2\left(c^2 \frac{\partial \rho}{\partial x_1} - \frac{\partial P}{\partial x_1}\right) \\ L_3 &= \lambda_3 \frac{\partial U_2}{\partial x_1} \\ L_4 &= \lambda_4 \frac{\partial U_3}{\partial x_1} \\ L_5 &= \lambda_5\left(\frac{\partial P}{\partial x_1} + \rho c \frac{\partial U_1}{\partial x_1}\right) \end{aligned} \tag{7.194}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The outgoing and incoming characteristic waves are associated with the characteristic velocities of the system (i.e eigenvalues), λ_i, as seen in Figure 7.88: Waves Leaving and Entering a Boundary Face on Inflow and Outflow Boundaries. The Wave Amplitudes are Shown with the Associated Eigenvalues for a Subsonic Flow Condition (p. 1517). These eigenvalues are given by:

$$\begin{aligned} \lambda_1 &= U_1 - c \\ \lambda_2 &= \lambda_3 = \lambda_4 = U_1 \\ \lambda_5 &= U_1 + c \end{aligned} \tag{7.195}$$

Figure 7.88: Waves Leaving and Entering a Boundary Face on Inflow and Outflow Boundaries. The Wave Amplitudes are Shown with the Associated Eigenvalues for a Subsonic Flow Condition



For subsonic flow leaving a boundary, four waves leave the domain (associated with positive eigenvalues λ_2, λ_3, λ_4, and λ_5) and one enters the domain (associated with negative eigenvalue λ_1). For subsonic flow entering a boundary, four waves enter the domain (associated with the negative eigenvalues λ_1, λ_2, λ_3, λ_4) and one leaves the domain (associated with a positive eigenvalue λ_5).

To solve Equation 7.192 (p. 1515) on a boundary, the amplitude of the incoming and outgoing waves must be first determined. The amplitude of outgoing waves are computed from Equation 7.194 (p. 1516) by using extrapolated values of flow derivatives $\frac{\partial P}{\partial x_1}$, $\frac{\partial \rho}{\partial x_1}$, $\frac{\partial U_1}{\partial x_1}$, $\frac{\partial U_2}{\partial x_1}$, and $\frac{\partial U_3}{\partial x_1}$ from inside the domain. The amplitude of the incoming waves are computed as follows. The amplitude of waves L_3, L_4, for tangential velocity components, is set to zero. The amplitude of the incoming pressure and entropy waves are computed from the Linear Relaxation Method (LRM) of Poinsot [116] (p. 5661) [117] (p. 5661). The LRM method sets the value of the incoming wave amplitude to be proportional to the differences between the local primitive variable on a boundary face and the imposed boundary value. The expression for the amplitudes depends on the boundary type as shown below:

1. **Pressure Outlet**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$L_1 = K(P - P_{exit}) \tag{7.196}$$

where P_{exit} is the imposed pressure at the exit boundary, K is the relaxation factor, and P is the local pressure value at the boundary.

In general, the desirable average pressure on a non-reflecting boundary can be either relaxed toward a pressure value at infinity or enforced to be equivalent to some desired pressure at the exit of the boundary.

In the case of a backflow, the pressure-based solver has two options for specifying pressure at the boundary; static pressure or total pressure. If the static pressure option is selected, the pressure at infinity is equal to the pressure defined in the boundary dialog box. If the total pressure option is selected, the pressure at infinity is a total pressure that is computed from the value in the dialog box. For the density-based solver, the total pressure option is used and no other options are available.

If you want the average pressure at the boundary to relax toward P at infinity (that is $P_{exit} = P_\infty$), the suggested K factor is given by:

$$K = \sigma_1 \left(1 - M_{max}^{\ 2}\right) \frac{c}{h} \tag{7.197}$$

where c is the acoustic speed, h is the domain size, M_{max} is the maximum Mach number in the domain, and σ_1 is the under-relaxation factor (default value is 0.15). On the other hand, if the desired average pressure at the boundary is to approach a specific imposed value at the boundary, then the K factor is given by:

$$K = \sigma_2 c \tag{7.198}$$

where the default value for σ_2 is 5.0

Important:

The desired average pressure option is only available for the density-based solver.

---

2. **Pressure Inlet**:

$$\begin{aligned} L_1 &= K(P - P_{exit}) \\ L_2 &= K\left[c^2\left(\rho - \rho_{exit}\right) - \left(P - P_{exit}\right)\right] \end{aligned} \tag{7.199}$$

where the imposed pressure, P_{exit}, and density, ρ_{exit}, are computed from the specified total pressure and total temperature.

3. **Mass Flux Boundary**:

$$\begin{aligned} L_1 &= -K\rho c(U_1 - U_{1,exit}) \\ L_2 &= Kc^2\left(\rho - \rho_{exit}\right) \end{aligned} \tag{7.200}$$

where the imposed exit velocity and density are computed from specific mass flux and total temperature.

4. **Velocity Inlet**:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$L_1 = -K\rho c(U_1 - U_{1,exit})$$
$$L_2 = Kc^2\left(\rho - \rho_{exit}\right) \tag{7.201}$$

where the imposed velocity, $U_{1,exit}$, is specified at the boundary and the imposed density is computed from the specified boundary temperature and extrapolated pressure.

7.7.2.4. Using the General Non-Reflecting Boundary Condition

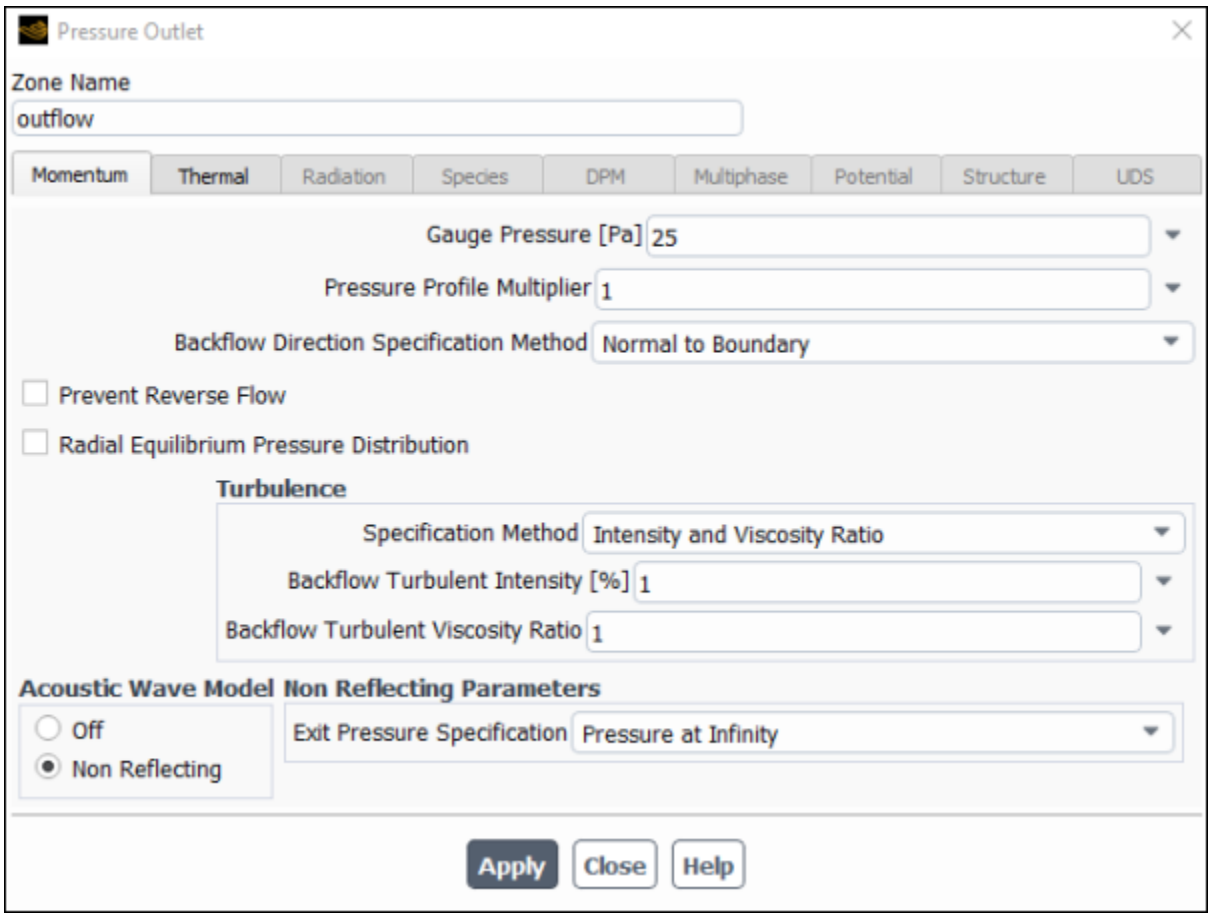
The general Non-Reflecting Boundary Condition is available for use in the **Pressure Outlet** dialog box when either the density-based (with ideal gas law) or pressure-based solvers are activated to solve for compressible flows. The general Non-Reflecting Boundary Condition is available for use in the **Pressure Inlet**, **Mass-Flow Inlet**, and **Velocity Inlet** dialog boxes when the pressure-based solver is activated to solve for compressible flows.

The example below shows you how to enable the general Non-Reflecting Boundary Condition in the **Pressure Outlet** dialog box. You would follow similar steps for the other boundary condition types mentioned above.

1. Select **pressure-outlet** from the **Boundary Conditions** task page and click the **Edit...** button.

2. In the **Pressure Outlet** dialog box, choose **Non Reflecting** under **Acoustic Wave Model**.

Figure 7.89: The Pressure Outlet Dialog Box With the Non-Reflecting Boundary Enabled



3. For the density-based solver, select one of the two **Exit Pressure Specification** options: **Pressure at Infinity** or **Average Boundary Pressure**. The pressure-based solver uses the **Pressure at Infinity** option and the **Exit Pressure Specification** drop-down list is not available.

   a. The **Pressure at Infinity** boundary is typically used in unsteady calculations or when the exit pressure value is imposed at infinity. The boundary is designed so that the pressure at the boundary relaxes toward the imposed pressure at infinity. The speed at which this relaxation takes place is controlled by the parameter, `sigma`, which can be adjusted in the TUI:

   `define` → `boundary-conditions` → `non-reflecting-bc` → `general-nrbc` → `set`

   In the `set/` submenu, you can set the `sigma` value. The default value for `sigma` is 0.15.

   b. The **Average Boundary Pressure** specification is usually used in steady-state calculations when you want to force the average pressure on the boundary to approach the exit pressure value. The matching of average exit pressure to the imposed average pressure is controlled by the parameter `sigma2` which can be adjusted in the TUI:

   `define` → `boundary-conditions` → `non-reflecting-bc` → `general-nrbc` → `set`

   In the `set/` submenu, you can set the `sigma2` value. The default value for `sigma2` is 5.0.

   Important:

   There is no guarantee that the `sigma2` value of 5.0 will force the average boundary pressure to match the specified exit pressure in all flow situations. In the case where the desired average boundary pressure has not been achieved, you can intervene to adjust the `sigma2` value so that the desired average pressure on the boundary is approached.

4. For the pressure-based solver, you can select one of two **Backflow Pressure Specification** options: **Static Pressure** or **Total Pressure**. For the density-based solver, the **Backflow Pressure Specification** is not shown and the **Total Pressure** option is used by default. Note that backflow is not allowed for pressure inlets, mass-flow inlets, or velocity inlets.

   Important:

   For the pressure-based solver, you should choose **Direction Vector** or **From Neighboring Cell** as the **Backflow Direction Specification Method** if the flow is tangential to the boundary. You should not select the **Normal to the Boundary** option for **Backflow Direction Specification Method** in this case because the face velocity components for this case will be computed from flux as zero during initialization. This initialization will cause the solver convergence to fail.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Usually, the solver can operate at higher CFL values without the NRBCs being turned on. Therefore, the best practice is to first achieve a good stable solution (not necessarily converged) before activating the non-reflecting boundary condition. In many flow situations, the CFL value must be reduced from the normal operation to keep the solution stable. This is particularly true with the density-based implicit solver since the boundary update is done in an explicit manner. A typical CFL value in the density-based implicit solver, with the NRBC activated, is 2.0 and 4.0 in the pressure-based solver.

7.7.3. Impedance Boundary Conditions

The impedance boundary condition (IBC) lies in between a traditional reflective boundary condition and a fully non-reflective boundary condition. It provides the ability to specify a partial reflection in the range from full-reflection to no-reflection. Impedance is a complex value; it is the reflection that changes the amplitude and the phase of the incoming wave. The use of impedance boundary conditions comes in cases where the flow in the simulation is highly influenced by reflected waves from objects outside the computational domain. In such cases the acoustic wave interaction from the larger domain can be modeled in the smaller domain through the use of impedance boundary conditions.

7.7.3.1. Restrictions and Limitations

The impedance boundary condition is available only in the pressure-based solver. It is incompatible with steady-state flow, multiphase, or compressible liquid models (**compressible-liquid** method for density).

7.7.3.2. Theory

Impedance specifies an acoustic resistance in the frequency domain. It is a characteristic of the properties of the media and specific geometry described by a ratio of the pressure perturbation to the normal velocity perturbation at the boundary (Blackstock [17] (p. 5656)). The specific impedance is calculated as follows:

$$\hat{Z}(\omega) = \frac{\hat{p}'}{\rho c \hat{u}'} \tag{7.202}$$

where apostrophe denotes acoustic perturbation and hat denotes quantity in the frequency domain.

Fluent is a time domain solver. It cannot use the impedance from the frequency domain directly. The above expression and all its variables have to be converted to the time domain. After the conversion the relation between pressure and normal velocity perturbations is expressed through a convolution integral.

$$p'(t) = \int_{-\infty}^{\infty} Z(\tau) u'(t-\tau) d\tau \tag{7.203}$$

If impedance, $Z(\tau)$, is unbounded in the time domain, then admittance is used (admittance is the inverse of impedance). Fluent uses the reflection coefficient instead of impedance/admittance, to uniformly treat unbounded cases (Fung [45] (p. 5657)). The reflection coefficient is a ratio between reflected and incoming wave amplitudes at the boundary. It is expressed through the impedance as:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\hat{R}(\omega)=\frac{\hat{Z}(\omega)-1}{\hat{Z}(\omega)+1} \tag{7.204}$$

Using a reflection coefficient, the relation between pressure and normal velocity perturbation is:

$$p'(t)-\rho c u'(t)=\int_{-\infty}^{\infty} R(\tau)\left[p'(t-\tau)+\rho c u'(t-\tau)\right]d\tau \tag{7.205}$$

The discretized form of this expression is used in Fluent to connect acoustic pressure and normal velocity. The computed acoustic perturbations are superimposed onto the pressure and velocity from non-reflecting boundary condition equations. The non-reflecting boundary condition equations provide mean flow values at the boundary, which drive the flow in the domain.

The data for the reflection coefficient are available in the frequency domain. As such they usually do not satisfy the causality and reality conditions. Fluent asks you to provide the reflection coefficient data in the form of a special approximation. This approximation is based on the system theory, which ensures that the reflection coefficient in the time domain will satisfy the above conditions (Fung [44] (p. 5657)). The reflection coefficient is represented as a sum of zero, first and second order systems. The zero system is described with a real value, the first order system is described with a real pole, and the second order system is described with a pair of complex conjugate poles. Introducing a system variable, $s=j\omega$ the complete approximation for the reflection coefficient is:

$$\hat{R}(s)=D+\sum_{k=1}^{N_1}\frac{A_k}{s+\lambda_k}+\sum_{l=1}^{N_2}\left(\frac{B_l+jC_l}{s+\alpha_l-j\beta_l}+\frac{B_l-jC_l}{s+\alpha_l+j\beta_l}\right) \tag{7.206}$$

where D is a real term, N_1 is a number of real poles, λ_k and A_k are real pole and its amplitude, N_2 is a number of complex conjugate pole pairs, α_l, β_l are real and imaginary part of the complex conjugate pole, B_l and C_l are real and imaginary part of the amplitude of the complex pole.

To obey the causality and reality conditions, real pole λ_k, real α_l and imaginary part β_l of the complex conjugate pole should be positive. The passivity condition requires that the absolute value of zero order term D be less than 1. The above restrictions are enforced in the user interface. In addition you should ensure that the absolute value of the reflection coefficient computed by this formula is less than 1.

The experimental data can be specific impedance, reflection coefficient, or absorption coefficient data, and can be obtained from measurements or from an acoustic solver. Processing these data using Fluent or a mathematics package will provide an approximation in terms of first and second order poles.

7.7.3.3. Using the Impedance Boundary Condition

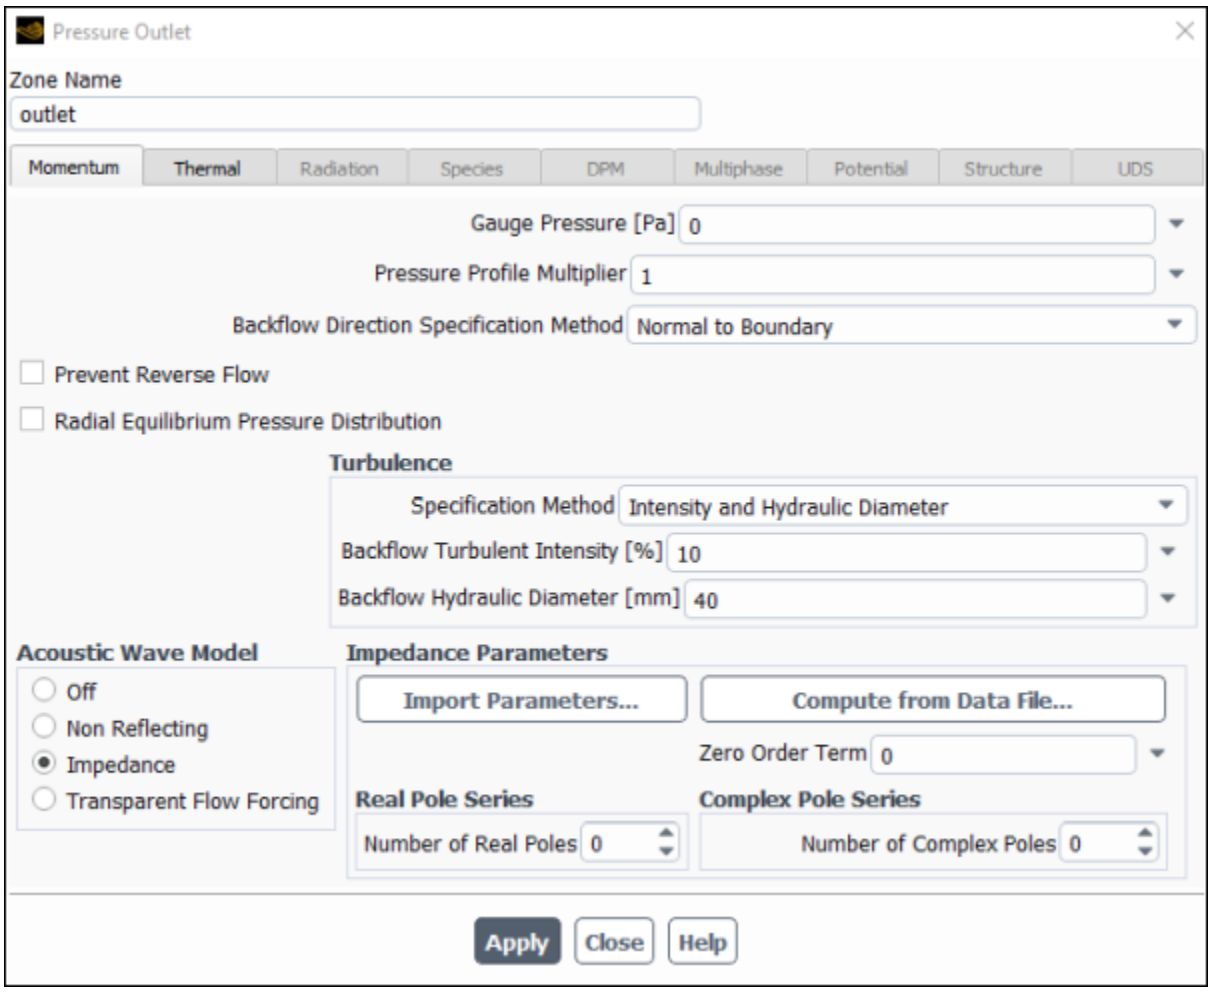
The example below shows you how to enable the impedance boundary condition (IBC) in the **Pressure Outlet** dialog box. Similarly, you can enable IBC in the **Pressure Inlet**, **Velocity Inlet**, and **Mass-Flow Inlet** dialog boxes for compressible flows with the pressure-based solver.

1. Select **pressure-outlet** from the **Boundary Condition** task page and click the **Edit...** button.

2. In the **Pressure Outlet** dialog box, choose **Impedance** under **Acoustic Wave Model**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The dialog box will expand to reveal **Impedance Parameters**.



3. Specify the data for the reflection coefficient in the **Impedance Parameters** group box. This can be done using one of the following methods:

   - If you have a pole / residue file that contains the terms of the approximation formula (Equation 7.206 (p. 1522)), click the **Import Parameters** button and select the file; the values will then be automatically entered in the various fields of the **Impedance Parameters** group box. For information about the proper format of this file as well as how to generate one from experimental impedance data in the frequency domain, see Calculating Impedance Parameters (p. 1524).

   - If you have a data file that contains experimental impedance data in the frequency domain, click the **Compute from Data File** button and use the **Impedance Data Fitting** dialog box that opens to compute the terms in the time domain and apply them to the various fields of the **Impedance Parameters** group box. For details, see Calculating Impedance Parameters (p. 1524).

   - Manually enter values in the various fields for the terms of the approximation formula (Equation 7.206 (p. 1522)):

     1. Specify the **Zero Order Term**, D.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Under **Real Pole Series**, set the **Number of Real Poles** and for each real pole specify the **Pole**, λ_k, and the **Amplitude**, A_k.

3. Under **Complex Pole Series**, set the **Number of Complex Poles** and for each complex pole pair, specify **Pole Real**, α_l, **Pole Imaginary**, β_l, **Amplitude Real**, B_l, and **Amplitude Imaginary**, C_l.

Important:

If flow is tangential to the boundary, then specify either **From Neighboring Cell** or **Direction Vector** for **Back flow Direction Specification Method**. Do not select **Normal to the boundary** because this computes the face velocity components from flux to zero values during initialization, which impairs solver convergence.

The IBC is implemented on top of the non-reflective boundary condition.

Note:

- The mean flow in the domain should be well established before enabling IBC.
- The cell acoustic Courant (CFL) number should be less than 1 in cells adjacent to the boundary where you define an impedance acoustic boundary condition. (For the definition of the **Cell Acoustic Courant Number**, refer to Field Function Definitions (p. 4133)).
- With the impedance acoustic boundary condition, you need to tighten the convergence criteria for continuity to 1e-4 in order to increase the number of coupling iterations between the impedance boundary condition calculation and the solver at each time step.

7.7.3.4. Calculating Impedance Parameters

You can use Fluent to read experimental impedance data in the frequency domain and then compute the terms needed for an approximation of the reflection coefficient as a series of poles / residues in the time domain. The calculation uses an algorithm based on the work of Gustavsen and Semlyen [56] (p. 5658). The terms of the pole / residue series can be directly applied to the various fields of the **Impedance Parameters** group box of a boundary condition dialog box, saved as a pole / residue file (which can be useful for setting up multiple boundary conditions and/or case files), and/or printed in the console; you can also write the fitted frequency / impedance data to an output file, which you can compare to the input data to evaluate how well it fits.

Note:

If you read experimental absorption coefficient data in the frequency domain, the terms of the pole / residue series that Fluent calculates may be different depending on which release or operating system you are using. Such differences will not affect the solution

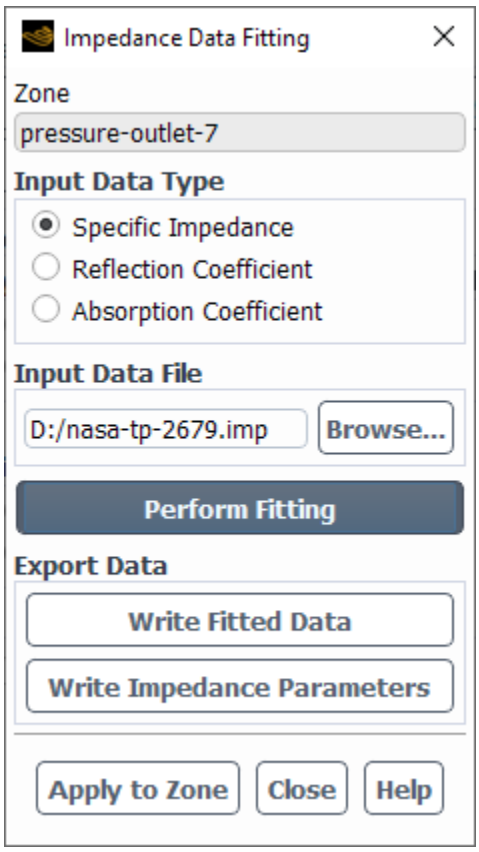
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

results, as only the curves of the fitted frequency / impedance data are used in the impedance boundary condition, and those curves will be consistent. You can verify this by comparing the output files of the fitted frequency / impedance data (see the steps that follow for details about writing such files).

To calculate and enter the impedance parameters, perform the following steps:

1. In the boundary condition dialog box (for example, the **Pressure Outlet** dialog box), click the **Compute from Data File** button in the **Impedance Parameters** group box, to open the **Impedance Data Fitting** dialog box.

   Figure 7.90: The Impedance Data Fitting Dialog Box



2. In the **Impedance Data Fitting** dialog box, make a selection from the **Input Data Type** for the experimental data in the frequency domain. The following types are available:

   - **Specific Impedance**

     This corresponds to Equation 7.202 (p. 1521).

   - **Reflection Coefficient**

     This corresponds to Equation 7.204 (p. 1522).

   - **Absorption Coefficient**

The absorption coefficient (α) is the ratio of the absorbed energy (E_a) to the incident energy (E_i):

$$\alpha = \frac{E_a}{E_i} \tag{7.207}$$

It relates to the reflection coefficient as follows:

$$|R| = \sqrt{1-\alpha} \tag{7.208}$$

3. Enter the name of the **Input Data File** or use the **Browse...** button to select it. The file must be in monitor format, with separate columns for the frequency and the data values. The following are examples:

   - For a specific impedance data file named `nasa-tp-2679.imp`:

```
"nasa-tp-2679"
"frequency" "impedance"
("frequency" "real" "imag")
5000.  0.41 -1.56
10000.  0.46 0.03

4. Click the **Perform Fitting** button to calculate the terms needed for an approximation of the reflection coefficient as a series of poles / residues in the time domain. The results are printed in the console (under `Zero Order Term`, `Number of Real Poles`, and so on, which correspond to the terms for the reflection coefficient according to the approximation formula Equation 7.206 (p. 1522)).

   Note that prior to clicking the **Perform Fitting** button, you have the option of revising a few additional settings for the fitting through the following text commands:

   - By default the algorithm will run 20 internal iterations; if this is inappropriate for your case, you can revise it using the following text command: `define/boundary-conditions/impedance-data-fitting/iterations`.
   - By default a convergence tolerance of 1e-6 is used for completing the iterative fitting procedure; if this is inappropriate for your case, you can revise it using the following text command: `define/boundary-conditions/impedance-data-fitting/convergence-tolerance`.
   - By default the minimum value of residues that are kept in the fitting is 1e-6. This residue check helps to eliminate parasitic poles. If the default value is inappropriate for your case, you can revise it using the following text command: `define/boundary-conditions/impedance-data-fitting/residue-tolerance`.
   - You can specify that messages are printed in the console as the fitting calculation progresses by entering the following text command: `define/boundary-conditions/impedance-data-fitting/verbosity 1`.

5. (optional) Click the **Write Fitted Data** button to write a file with fitted frequency / impedance data. The number of lines corresponds to the number of lines in the input data file, and there are separate columns for the frequency and the real and imaginary values. This file can be compared to the input data to evaluate how well it fits.

6. (optional) Click the **Write Impedance Parameters** button to write a pole / residue file with the impedance parameters, which can then be imported using the **Import Parameters** button of a boundary condition dialog box. Such a file can be useful when setting up multiple boundary conditions and/or case files. The following is an example of the format of a pole / residue file:

   ```
   Impedance parameters for nasa-tp-2679.imp:
   Zero Order Term
   6.227176322918e-01
   ```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
Number of Real Poles
 0
Number of Complex Conjugate Poles
 2
Pole Real           Pole Imaginary      Amplitude Real       Amplitude Imaginary
3.462578756313e+03  5.077495917952e+03  -5.463369722031e+03  -2.849664452670e+03
4.754179871958e+03  1.663686613863e+04  -1.614972036282e+03  -5.411609140947e+03
```

7. Click the **Apply to Zone** button to enter the results in the appropriate fields in the **Impedance Parameters** group box of the boundary condition dialog box.

8. Close the **Impedance Data Fitting** dialog box.

9. In the boundary condition dialog box, verify that the **Impedance Parameters** are appropriate and click the **Apply** button.

As an alternative to using the **Impedance Data Fitting** dialog box in a Fluent session, you can instead use the `impedance` utility to calculate the terms of the pole / residue series from a data file, print them, and optionally write them to a file. This utility has some additional functionality, which may be useful in some circumstances. To use the `impedance` utility, enter the following at a command prompt in a terminal or command window:

`utility impedance` [`--help`] [`-p` *P*] [`-f` *F*] [`-i` *I*] [`-t` *T*] [`-r` *R*] [`-y` *Y*] [`-m` *M*] [`-v` *V*] *I* [*R C*]

Note:

The items enclosed in square brackets are optional. Do not type the square brackets.

- `--help` (optional) prints the arguments available for the `impedance` utility.
- `-p` *P* (optional) specifies that the pole / residue mapping data is also written to an output file named *P*.
- `-f` *F* (optional) specifies that fitted frequency / impedance data is also written to an output file named *F*, with separate columns for the frequency and the real and imaginary values. This output file can be compared to the input data to evaluate how well it fits.
- `-i` *I* (optional) specifies that the algorithm uses a specified number (*I*) of internal iterations. By default, 20 iterations will be run.
- `-t` *T* (optional) sets the convergence tolerance (which is an accuracy that is used for completing the iterative fitting procedure) to *T*. By default, the tolerance is set to 1e-6.
- `-r` *R* (optional) sets the residue tolerance (that is, the minimum value of residues that are kept in the fitting) to *R*. This residue check helps to eliminate parasitic poles. By default, the residue tolerance is set to 1e-6.
- `-y` *Y* (optional) specifies the type of data file you are reading. *Y* can be `impedance` (for specific impedance data, which is the default), `reflection` (for reflection coefficient data), or `absorption` (for absorption coefficient data).
- `-m` *M* (optional) can be used with `-y absorption`, and specifies the phase of the absorption coefficient. *M* can be `zero` (the default) or `random`.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- `-v` *V* (optional) sets the verbosity of the progress messages. *V* can be `0` (the default, which prints no progress messages during the calculation) or `1` (which prints messages in the console as the fitting calculation progresses).
- *I* must be replaced with the name of the input file, which provides experimental data in monitor format with separate columns for the frequency and the data.
- *R* and *C* (optional) allow you to specify the number of poles (real and complex conjugate, respectively) that you want used during fitting. With this option, you must ensure that the numbers you enter are appropriate for the data you provide, such that:

$$n \geq 1+R+2C \tag{7.209}$$

  where *n* is the number of data points in your input file. When multiple combinations of values for *R* and *C* can satisfy the previous equation, you should ensure that the values you use yield the lowest possible RMS error (which is the root mean square difference between the fit and the input data, and is printed at the end of the calculation).

Note:

It is recommended that you omit *R* and *C*; when omitted, Fluent will automatically use numbers of poles that yield the lowest RMS error.

The following example demonstrates the use of the `impedance` utility from a command prompt, using the input file described previously.

```
utility impedance nasa-tp-2679.imp -p par.pr -f fitted.imp
```

The following will be printed:

```
command to execute: "python" "C:\ANSYS Inc\v241\fluent\fluent24.1.0\utility\impedance\impedance.pyc"
nasa-tp-2679.imp -p par.pr -f fitted.imp
Impedance parameters for nasa-tp-2679.imp:

```

The data printed in the terminal / command window and written in the output file named `par.pr` (under `Zero Order Term`, `Number of Real Poles`, and so on) is for the reflection coefficient (according to the approximation formula Equation 7.206 (p. 1522)) and can be imported or entered in the **Impedance Parameters** group box of a boundary condition dialog box (as described in Using the Impedance Boundary Condition (p. 1522)).

A frequency / impedance output file named `fitted.imp` will also be created, containing real and imaginary values for the frequencies defined in the input file.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.7.4. Transparent Flow Forcing Boundary Conditions

It is often desirable in simulations to cut a domain down to a smaller region to model only a part of the larger domain. The treatment at the boundaries created when doing so should be consistent with a slice through the larger domain. That is, incoming transients should be allowed to enter the computational domain and outgoing transients should leave the domain without reflections. Artificial numerical reflections at the boundaries can significantly affect the predicted flow, particularly if the geometry of the numerical domain has Eigen-frequencies that match the frequencies of physical waves propagating through the flow.

The transparent flow forcing treatment provides the capability to model incoming waves while allowing outgoing waves to pass through the boundaries without reflection. It is available in transient simulations of compressible flow using the pressure-based solver and can be applied for velocity inlets, mass-flow inlets, pressure inlets, and pressure outlets.

7.7.4.1. Restrictions and Limitations

The transparent flow forcing condition is available only in the pressure-based solver and it is incompatible with steady-state flow, multiphase, and compressible liquid models (those using the compressible-liquid method for density).

7.7.4.2. Theory

The transparent flow forcing boundary condition is implemented on top of the non-reflecting boundary condition. The non-reflecting part of the boundary condition drives the mean flow. The transient flow at the boundary is split into two waves [74] (p. 5659): incoming wave, $W_{in}\left(\vec{r},t\right)$, and outgoing wave, $W_{out}\left(\vec{r},t\right)$. In the acoustic limit, the intensities of the waves are expressed through pressure and normal velocity perturbations as:

$$W_{in}\left(\vec{r},t\right)=p'+zu'_n$$
$$W_{out}\left(\vec{r},t\right)=p'-zu'_n$$

where $z=\rho c$ is the impedance of the mean flow with density, ρ, and speed of sound, c. The outgoing wave intensity, $W_{out}\left(\vec{r},t\right)$, is computed internally while the incoming wave intensity, $W_{in}\left(\vec{r},t\right)$, is user-specified through a user-defined profile.

7.7.4.3. Using the Transparent Flow Forcing Boundary Condition

The transparent flow forcing (TFF) boundary condition is available at velocity inlets, mass-flow inlets, pressure inlets, and pressure outlets when simulating transient compressible flow using the pressure-based solver. The steps for using the transparent flow forcing boundary condition are as follows:

1. Create a profile for the incoming wave intensity on the boundary. The profile can be created either as a profile file as described in Profiles (p. 1540) or using the `DEFINE_PROFILE` macro as described in Fluent Customization Manual. In the profile definition, you will specify the wave intensity as a function of position and time. For the incoming wave, the pressure and normal velocity perturbations satisfy the relation:

$$p'=zu'_n$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Using this relation the incoming wave intensity at the boundary can be computed from any of the flow perturbation quantities.

- from acoustic pressure, p'

$$W_{in} = 2p'$$

- from acoustic velocity, u'_n

$$W_{in} = 2zu'_n$$

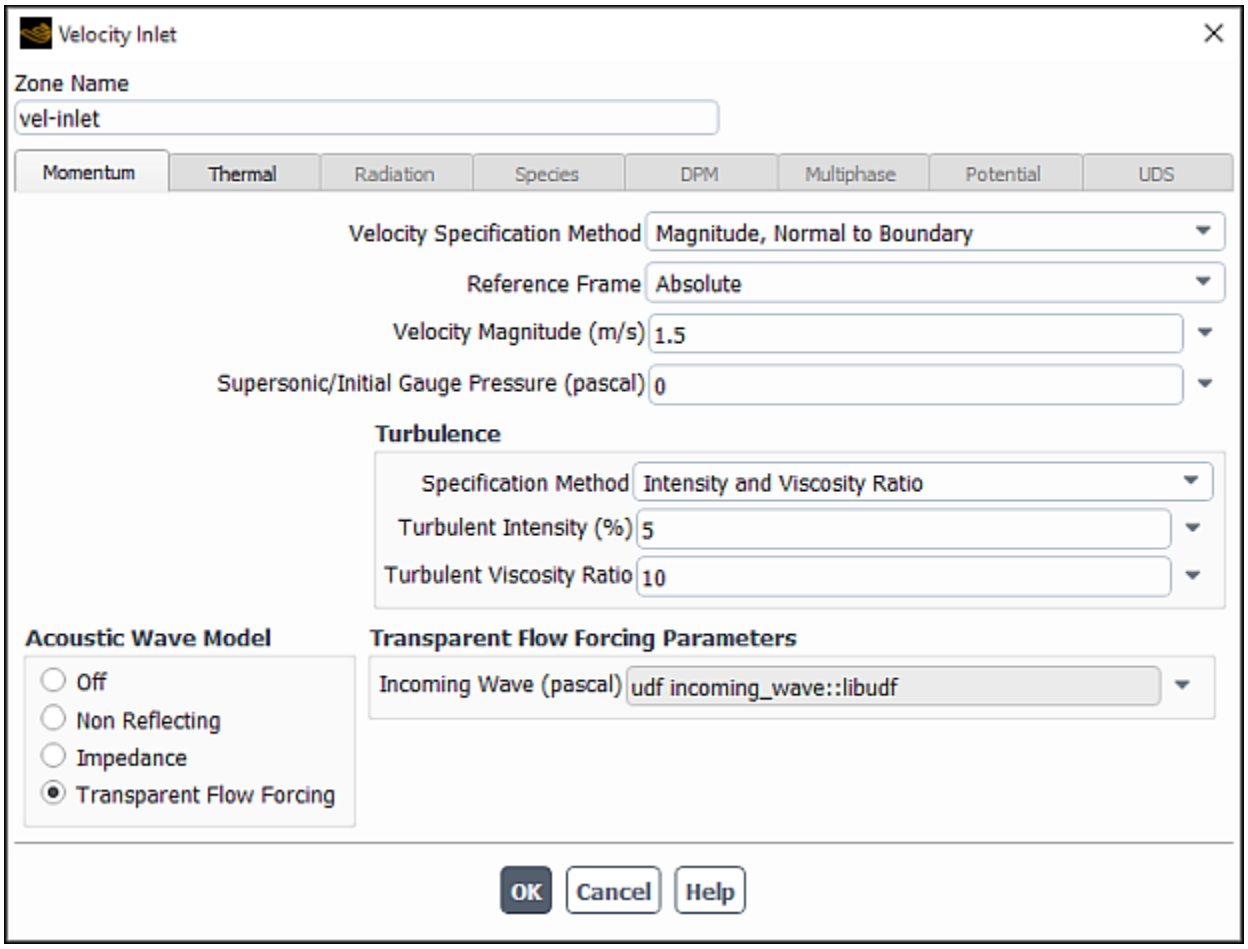
- from acoustic mass flux, m'_n

$$W_{in} = 2cm'_n$$

where c is the speed of sound and $z = \rho c$ is the acoustic impedance.

2. Open the boundary condition settings dialog box for the boundary zone of interest (Setting Cell Zone and Boundary Conditions (p. 1281)).
3. On the **Momentum** tab, select **Transparent Flow Forcing** under **Acoustic Wave Model**.
4. Under **Transparent Flow Forcing Parameters**, select your profile from the drop-down list next to **Incoming Wave**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Important:

- If flow is tangential to the boundary, then specify either **From Neighboring Cell** or **Direction Vector** for **Back flow Direction Specification Method**. Do not select **Normal to the boundary** because this computes the face velocity components from flux to zero values during initialization, which impairs solver convergence.
- The TFF condition is implemented on top of the non-reflective boundary condition. Choose a time step size that will not make the CFL number exceed a value of 1 in the cells adjacent to the TFF boundary.
- The mean flow in the domain should be well established before enabling TFF.

7.8. User-Defined Fan Model

The user-defined fan model in Ansys Fluent allows you to periodically regenerate a profile file that can be used to specify the characteristics of a fan, including pressure jump across the fan, and radial and swirling components of velocity generated by the fan.

For example, consider the calculation of the pressure jump across the fan. You can, through the standard interface, input a constant for the pressure jump, specify a polynomial that describes the

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

pressure jump as a function of axial velocity through the fan, or use a profile file that describes the pressure jump as a function of the axial velocity or location at the fan face. If you use a profile file, the same profile will be used consistently throughout the course of the solution. Suppose, however, that you want to change the profile as the flow field develops. This would require a periodic update to the profile file itself, based upon some instructions that you supply. The user-defined fan model is designed to help you do this.

To use this model, you need to generate an executable that reads a fan profile file that is written by Ansys Fluent, and writes out a modified one, which Ansys Fluent will then read. The source code for this executable can be written in any programming language (Fortran or C, for example). Your program will be called and executed automatically, according to inputs that you supply through the standard interface.

Information about the user-defined fan model is provided in the following sections.

7.8.1. Steps for Using the User-Defined Fan Model

7.8.2. Example of a User-Defined Fan

7.8.1. Steps for Using the User-Defined Fan Model

To make use of the user-defined fan model, follow the steps below.

1. In your model, identify one or more interior faces to represent one or more fan zones.

   Setup → **Boundary Conditions**

2. Input the name of your executable and the instructions for reading and writing profile files in the User-Defined Fan Model Dialog Box (p. 5589).

   User Defined → **Model Specific** → **Fan Model...**

3. Initialize the flow field and the profile files.

4. Enter the fan parameters using the standard Fan Dialog Box (p. 4948) (opened from the Boundary Conditions Task Page (p. 4937)).

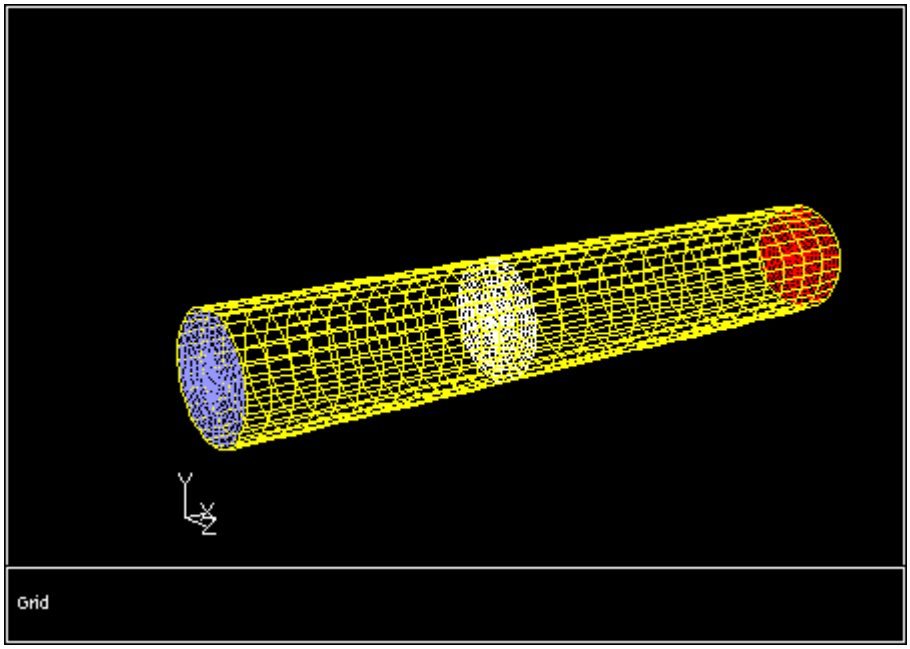
5. Perform the calculation.

7.8.2. Example of a User-Defined Fan

Usage of the user-defined fan model is best demonstrated by an example. With this in mind, consider the domain shown in Figure 7.91: The Inlet, Fan, and Pressure Outlet Zones for a Circular Fan Operating in a Cylindrical Domain (p. 1534). An inlet supplies air at 10 m/s to a cylindrical region, 1.25 m long and 0.2 m in diameter, surrounded by a symmetry boundary. At the center of the flow domain is a circular fan. A pressure outlet boundary is at the downstream end.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.91: The Inlet, Fan, and Pressure Outlet Zones for a Circular Fan Operating in a Cylindrical Domain



Solving this problem with the user-defined fan model will cause Ansys Fluent to periodically write out a radial profile file with the current solution variables at the fan face. These variables (static pressure, pressure jump, axial, radial, and swirling (tangential) velocity components) will represent averaged quantities over annular sections of the fan. The sizes of the annular regions are determined by the size of the fan and the number of radial points to be used in the profiles.

Once the profile file is written, Ansys Fluent will invoke an executable, which will perform the following tasks:

1. Read the profile file containing the current flow conditions at the fan.
2. Perform a calculation to compute new values for the pressure jump, radial velocity, and swirl velocity for the fan.
3. Write a new profile file that contains the results of these calculations.

Ansys Fluent will then read the new profile file and continue with the calculation.

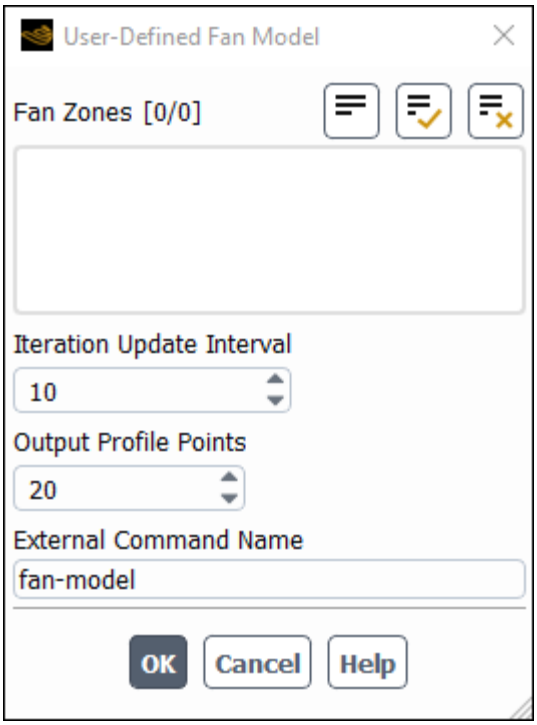
7.8.2.1. Setting the User-Defined Fan Parameters

Specification of the parameters for the user-defined fan begins in the User-Defined Fan Model Dialog Box (p. 5589) (Figure 7.92: The User-Defined Fan Model Dialog Box (p. 1535)).

User Defined → Model Specific → Fan Model...

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.92: The User-Defined Fan Model Dialog Box



In this dialog box, you can select the fan zone(s) on which your executable will operate under **Fan Zones**. In this example, there is only one fan, **fan-8**. If you have multiple fan zones in a simulation, for which you have different profile specifications, you can select them all at this point. Your executable will be able to differentiate between the fan zones because the zone ID for each fan is included in the solution profile file. The executable will be invoked once for each zone, and separate profile files will be written for each.

The executable file will be called on to update the profile file periodically, based on the input for the **Iteration Update Interval**. An input of `10`, as shown in the dialog box, means that the fan executable in this example will act every 10 iterations to modify the profile file.

The number of points in the profile file to be written by Ansys Fluent is entered under **Output Profile Points**. This profile file can have the same or a different number of points as the one that is written by the external executable.

Finally, the name of the executable should be entered under **External Command Name**. In the current example, the name of the executable is `fan-model`.

Important:

If the executable is not located in your working directory, then you must type the complete path to the executable.

7.8.2.2. Sample User-Defined Fan Program

The executable file will be built from the Fortran program, `fantest.f`, which is shown below.

```
c
c  This program is invoked at intervals by Ansys Fluent to
```

```
c  read a profile-format file that contains radially
c  averaged data at a fan face, compute new pressure-jump
c  and swirl-velocity components, and write a new profile
c  file that will subsequently be read by Ansys Fluent to
c  update the fan conditions.
c
c  Usage: fantest input_profile output_profile
c
  integer npmax
  parameter (npmax = 900)
  integer inp         ! input: number of profile points
  integer iptype      ! input: profile type (0=radial, 1=point)
  real ir(npmax)      ! input: radial positions
  real ip(npmax)      ! input: pressure
  real idp(npmax)     ! input: pressure-jump
  real iva(npmax)     ! input: axial velocity
  real ivr(npmax)     ! input: radial velocity
  real ivt(npmax)     ! input: tangential velocity
  character*80 zoneid
  integer rfanprof    ! function to read a profile file
  integer status
c
  status = rfanprof(npmax,zoneid,iptype,
 $  inp,ir,ip,idp,iva,ivr,ivt)
  if (status.ne.0) then
    write(*,*) 'error reading input profile file'
  else
    do 10 i = 1, inp
      idp(i) = 200.0 - 10.0*iva(i)
      ivt(i) = 20.0*ir(i)
      ivr(i) = 0.0
 10  continue
  call wfanprof(6,zoneid,iptype,inp,ir,idp,ivr,ivt)
  endif
  stop
  end
```

After the variable declarations, which have comments on the right, the subroutine `rfanprof` is called to read the profile file, and pass the current values of the relevant variables (as defined in the declaration list) to `fantest`. A loop is done on the number of points in the profile to compute new values for:

- The pressure jump across the fan, `idp`, which in this example is a function of the axial velocity, `iva`.
- The swirling or tangential velocity, `ivt`, which in this example is proportional to the radial position, `ir`.
- The radial velocity, `ivr`, which in this example is set to zero.

After the loop, a new profile is written by the subroutine `wfanprof`, shown below. (For more information on profile file formats, see Profile File Formats (p. 1541).)

```
 subroutine wfanprof(unit,zoneid,ptype,n,r,dp,vr,vt)
c
c  writes an Ansys Fluent profile file for input by the
c  user fan model
c
  integer unit       ! output unit number
  character*80 zoneid
  integer ptype      ! profile type (0=radial, 1=point)
  integer n          ! number of points
  real r(n)          ! radial position
  real dp(n)         ! pressure jump
  real vr(n)         ! radial velocity
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
  real vt(n)         ! tangential velocity
  character*6 typenam
  if (ptype.eq.0) then
    typenam = 'radial'
  else
    typenam = 'point'
  endif
  write(unit,*) '((', zoneid(1:index(zoneid,'\0')-1), ' ',
 $  typenam, n, ')'
  write(unit,*) '(r'
  write(unit,100) r
  write(unit,*) ')'
  write(unit,*) '(pressure-jump'
  write(unit,100) dp
  write(unit,*) ')'
  write(unit,*) '(radial-velocity'
  write(unit,100) vr
  write(unit,*) ')'
  write(unit,*) '(tangential-velocity'
  write(unit,100) vt
  write(unit,*) ')'
 100 format(5(e15.8,1x))
  return
  end
```

This subroutine will write a profile file in either radial or point format, based on your input for the integer `ptype`. (See Profiles (p. 1540) for more details on the types of profile files that are available.) The names that you use for the various profiles are arbitrary. Once you have initialized the profile files, the names you use in `wfanprof` will appear as profile names in the Fan Dialog Box (p. 4948).

7.8.2.3. Initializing the Flow Field and Profile Files

The next step in the setup of the user-defined fan is to initialize (create) the profile files that will be used. To do this, first initialize the flow field with the Solution Initialization Task Page (p. 5125) (using the velocity inlet conditions, for example), and then type the command `(update-user-fans)` in the console window. (The parentheses are part of the command, and must be typed in.)

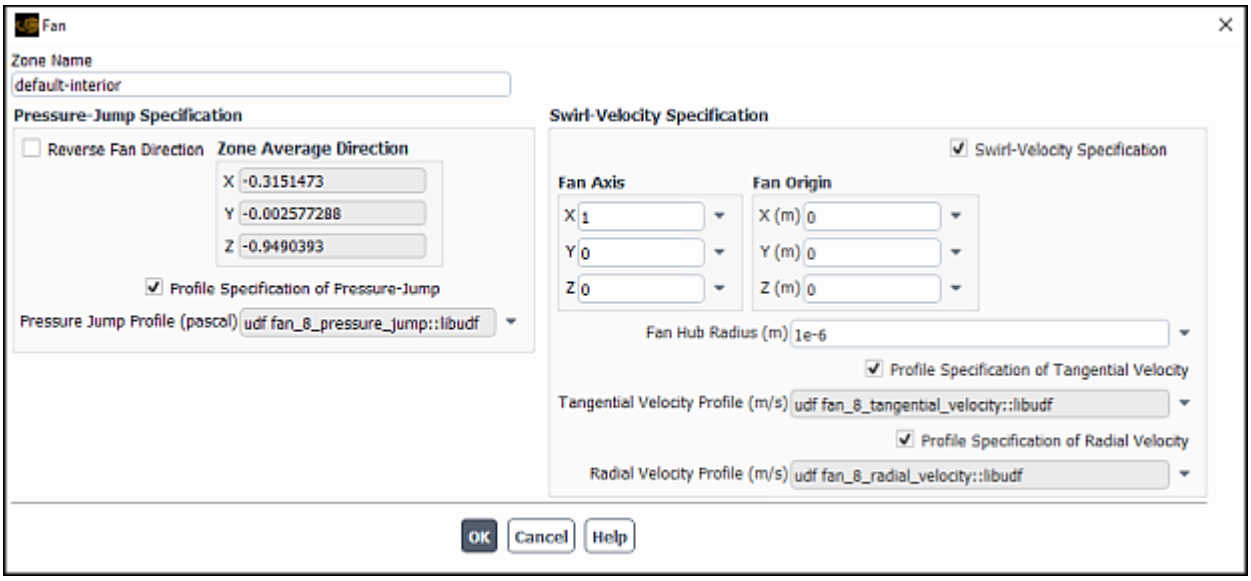
This will create the profile names that are given in the subroutine `wfanprof`.

7.8.2.4. Selecting the Profiles

Once the profile names have been established, you will need to visit the Fan Dialog Box (p. 4948) (Figure 7.93: The Fan Dialog Box (p. 1538)) to complete the problem setup. (See Fan Boundary Conditions (p. 1480) for general information on using the **Fan** dialog box.)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.93: The Fan Dialog Box



At this time, the **Fan Axis**, **Fan Origin**, and **Fan Hub Radius** can be entered, along with the choice of profiles for the calculation of pressure jump, tangential velocity, and radial velocity. With the profile options enabled, you can select the names of the profiles from the drop-down lists. In the dialog box above, the selected profiles are named **fan_8_pressure_jump**, **fan_8_tangential_velocity**, and **fan_8_radial_velocity**, corresponding to the names that were used in the subroutine `wfanprof`.

7.8.2.5. Performing the Calculation

The solution is now ready to run. As it begins to converge, the report in the console window shows that the profile files are being written and read every 10 iterations:

```
    iter   continuity   x-velocity   y-velocity   z-velocity          k

```

The file `fan-8-out.prof` is written out by Ansys Fluent and read by the executable `fantest`. It contains values for pressure, pressure jump, axial velocity, radial velocity, and tangential velocity

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

at 20 radial locations at the site of the fan. The file `fan-8-in.prof` is generated by `fantest` and contains updated values for pressure jump and radial and tangential velocity only. It is therefore a smaller file than `fan-8-out.prof`. The prefix for these files takes its name from the fan zone with which the profiles are associated. An example of the profile file `fan-8-in.prof` is shown below. This represents the last profile file to be written by `fantest` during the convergence history.

```

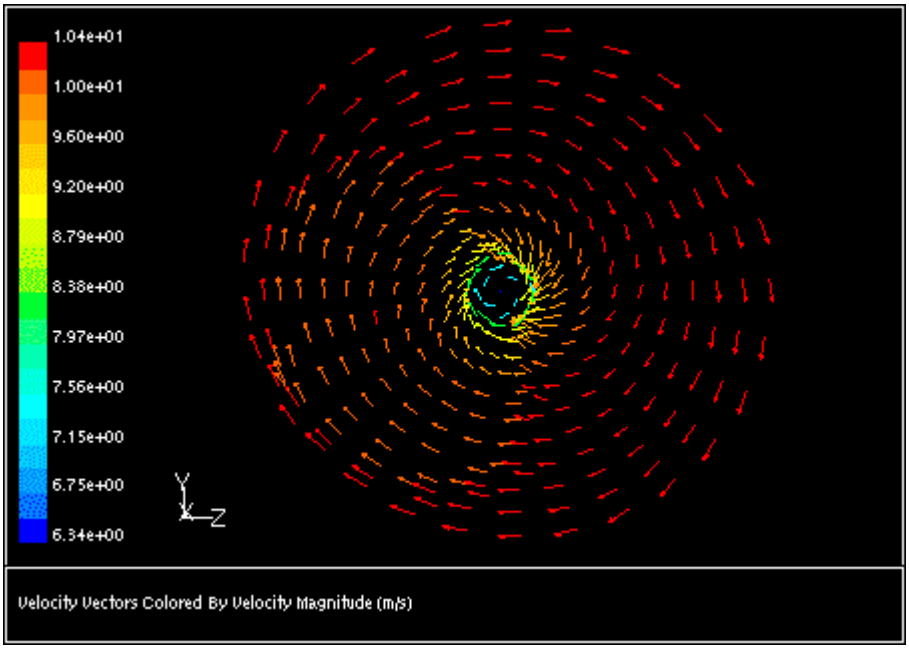
7.8.2.6. Results

A plot of the transverse velocity components at the site of the fan is shown in Figure 7.94: Transverse Velocities at the Site of the Fan (p. 1539). As expected, there is no radial component, and the tangential (swirling) component increases with radius.

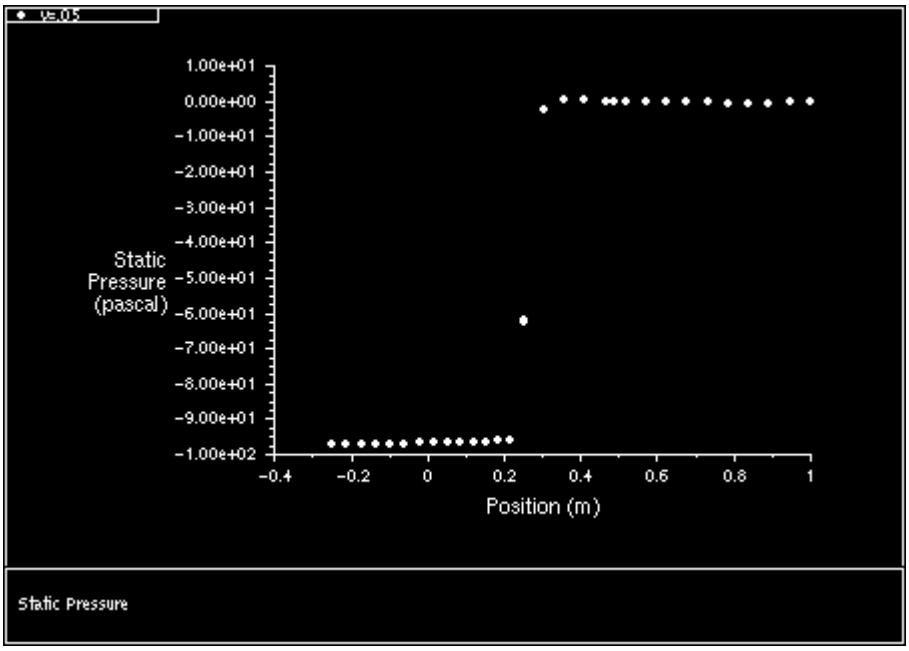
Figure 7.94: Transverse Velocities at the Site of the Fan



As a final check on the result, an XY plot of the static pressure as a function of x position is shown (Figure 7.95: Static Pressure Jump Across the Fan (p. 1540)). This XY plot is made on a line at y =0.05 m, or at about half the radius of the duct. According to the input file shown above, the pressure jump at the site of the fan should be approximately 97.8 Pa/m. Examination of the figure supports this finding.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.95: Static Pressure Jump Across the Fan



7.9. Profiles

Profiles can be boundary conditions, cell zone conditions, and initial conditions for discrete phases. Ansys Fluent provides a very flexible profile definition mechanism. This feature allows you to use experimental data, data calculated by an external program, or data written from a previous solution using the Write Profile Dialog Box (p. 4936) (as described in Reading and Writing Profile Files (p. 940)) as the boundary condition for a variable.

Information about profiles is presented in the following subsections:

7.9.1. Profile Specification Types

7.9.2. Profile File Formats

7.9.3. Using Profiles

7.9.1. Profile Specification Types

The following is a list of the six types of profiles that can be read into Ansys Fluent, as well as information about the interpolation method employed by Ansys Fluent for each type.

- Point profiles are specified by an unordered set of n points: $\left(x_i, y_i, v_i\right)$ for 2D problems or $\left(x_i, y_i, z_i, v_i\right)$ for 3D problems, where $1 \le i \le n$. Profiles written using the **Write Profile** dialog box and profiles of experimental data in random order are examples of point profiles.

  Ansys Fluent will interpolate the point cloud to obtain values at the boundary faces. The default interpolation method for the unstructured point data is zeroth order. That is, for each cell face at the boundary, the solver uses the value from the profile file located closest to the cell. Therefore, to get an accurate specification of an inlet profile using the default interpolation method, your

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

profile file should contain a sufficiently high point density. For information about other available interpolation methods for point profiles, see Using Profiles (p. 1546).

- Line profiles are specified for 2D problems by an ordered set of n points: $\left(x_i, y_i, v_i\right)$, where $1 \le i \le n$. Zeroth-order interpolation is performed between the points. An example of a line profile is a profile of data obtained from an external program that calculates a boundary-layer profile.

- Mesh profiles are specified for 3D problems by an m by n mesh of points: $\left(x_{ij}, y_{ij}, z_{ij}, v_{ij}\right)$, where $1 \le i \le m$ and $1 \le j \le n$. Zeroth-order interpolation is performed between the points. Examples of mesh profiles are profiles of data from a structured mesh solution and experimental data in a regular array.

- Radial profiles are specified for 2D and 3D problems by an ordered set of n points: $\left(r_i, v_i\right)$, where $1 \le i \le n$. The data in a radial profile are a function of radius only. Linear interpolation is performed between the points, which must be sorted in ascending order of the r field. The axis for the cylindrical coordinate system is determined as follows:

  – For 2D problems, it is the z -direction vector through (0,0).

  – For 2D axisymmetric problems, it is the x -direction vector through (0,0).

  – For 3D problems involving a swirling fan, it is the fan axis defined in the Fan Dialog Box (p. 4948) (unless you are using local cylindrical coordinates at the boundary, as described below).

  – For 3D problems without a swirling fan, it is the rotation axis of the adjacent fluid zone, as defined in the Fluid Dialog Box (p. 4909) (unless you are using local cylindrical coordinates at the boundary, as described below).

  – For 3D problems in which you are using local cylindrical coordinates to specify conditions at the boundary, it is the axis of the specified local coordinate system.

- Axial profiles are specified for 3D problems by an ordered set of n points: $\left(z_i, v_i\right)$, where $1 \le i \le n$. The data in an axial profile are a function of the axial direction. Linear interpolation is performed between the points, which must be sorted in ascending order of the z field.

- Transient profiles are specified for 2D and 3D profiles by an ordered set of n points: $\left(t_i, v_{0,i}, v_{1,i}, v_{2,i}, \ldots\right)$. Linear interpolations are done between the points which must be sorted in ascending order of the t (time or crank angle) field. Examples of transient profiles are transient cell zone and boundary conditions (see Transient Cell Zone and Boundary Conditions (p. 1499)) and point properties for particle injections (see Point Properties for Transient Injections (p. 2775)).

7.9.2. Profile File Formats

There are two profile format options:

7.9.2.1. Standard Profiles

7.9.2.2. CSV Profiles

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.9.2.1. Standard Profiles

The format of the profile files is fairly simple. The file can contain an arbitrary number of profiles. Each profile consists of a header that specifies the profile name, profile type (`point`, `line`, `mesh`, `radial`, or `axial`), and number of defining points, and is followed by an arbitrary number of named "fields". Some of these fields contain the coordinate points and the rest contain boundary data.

Important:

Keep profile names to 64 characters or less. If the profile name contains more than 64 characters, Fluent truncates the name to the first 64 characters.

All quantities, including coordinate values, must be specified in SI units because Ansys Fluent does not perform unit conversion when reading profile files.

Parentheses are used to delimit profiles and the fields within the profiles. Any combination of tabs, spaces, and newlines can be used to separate elements.

Important:

In the general format description below, " | " indicates that you should input only one of the items separated by |'s and " `...` " indicates a continuation of the list.

```
((profile1-name point|line|radial n)
 (field1-name a1 a2 ... an)
 (field2-name b1 b2 ... bn)
.
.
.
 (fieldf-name f1 f2 ... fn))

((profile2-name mesh m n)
  (field1-name  a11 a12 ... a1n
                a21 a22 ... a2n
                .
                .
                .
                am1 am2 ... amn)
.
.
.
(fieldf-name   f11  f12 ... f1n
               f21  f22 ... f2n
               .
               .
               .
               fm1 fm2 ... fmn))
```

Profile names must have all lowercase letters (for example, `name`). Uppercase letters in profile names are not acceptable. Each profile of type `point`, `line`, and `mesh` must contain fields with names `x`, `y`, and, for 3D, `z`. Each profile of type `radial` must contain a field with name `r`. Each profile of type `axial` must contain a field with name `z`. The rest of the names are arbitrary, but must be valid Scheme symbols. For compatibility with old-style profile files, if the profile type is missing, `point` is assumed.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.9.2.1.1. Example

A typical usage of a profile file is to specify the profile of the boundary layer at an inlet. For a compressible flow calculation, this will be done using profiles of total pressure, k, and ε. For an incompressible flow, it might be preferable to specify the inlet value of streamwise velocity, together with k and ε.

Below is an example of a profile file that does this:

```
((turb-prof point 8)
 (x
     4.00000E+00  4.00000E+00  4.00000E+00  4.00000E+00

 )
```

7.9.2.2. CSV Profiles

CSV profiles are compatible with spreadsheets and are available for both reading and writing in Fluent. Many profile types can be written in CSV format, including:

- Radial
- Axial
- Point (X, Y, Z)
- Transient
- Transient-Periodic

If writing a profile using the **Write Profile** dialog box, you can save the profile in CSV format by saving with a `.csv` extension.

Files may also be written by other Ansys products including:

- Ansys Mechanical (**EXOPTION**)
- Ansys CFX (Profile Data Format)

Applications using the `.csv` profile format include:

- Aerodynamic Damping (Blade Flutter Analysis) (p. 1940)
- Blade Film Cooling for Gas Turbines (p. 1981)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Formatting Rules:

CSV profiles must be setup so they can be read and interpreted correctly in Fluent:

1. The profile file must contain the section identifiers shown in Table 7.4:**CSV Profile Section Identifiers** (p. 1544). Some of the identifiers are optional because not all profiles will contain these additional fields, and they are noted as such. The ordering presented in the table is the ordering that should be present in the file.

   Table 7.4: CSV Profile Section Identifiers

Section Identifiers	Remark
[Name]	The next line should have the profile name. *Note- if the profile name has space characters, they will be replaced with '-' (space character is not allowed).*
(Optional) [Parameters]	The next line should list the name of each parameter and its value. Parameters that have units should have the appropriate unit in brackets next to the value of the parameter.
(Optional) [Spatial Fields]	The next line should list the names and units of the Cartesian coordinate system. This indicates whether the profile is 1D, 2D, or 3D (with the number of values corresponding to the dimensions of the profile).
[Data]	Data values begin on the next line.
(Optional) [Faces]	The next lines provide the face-node connectivity that allows for previewing the profile as a surface.

2. After the `[Data]` identifier you must label the type of data that you are providing; refer to Table 7.5: Profile Types and the Corresponding Required Field Labels (p. 1544) for the correct labels. If Fluent does not find one of the expected labels, the profile read will fail.

   Table 7.5: Profile Types and the Corresponding Required Field Labels

Profile Type	Required Field Label
radial	radius
axial	axis
point	X, Y, Z
transient	time, angle
transient-periodic	time-periodic, angle-periodic

Important:

The following labels are reserved for X-axis functions: `x`, `y`, `z`, `r`, `time`, and `angle`. If your file contains fields labeled with any of these reserved names, then those fields

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

will be treated as X-axis functions. For fields to be considered as Y-axis functions, you must use names that are not reserved for X-axis functions.

3. If there is an unsupported section identifier, Fluent ignores the section and looks for the `[Name]` and `[Data]` section identifiers.

4. Multiple profiles may be included in a single file.

Important:

- Only use commas as value separators. Space characters should not be used as they will confuse external spreadsheet applications.
- If a profile contains only `Name` and `Data` fields, only SI values are supported. Quantities cannot be entered with units. However, if your profile contains any of the additional fields, then units must be provided and they are not required to be SI.

CSV Profile File Examples

A file containing one profile:

```
[Name]
outlet
[Data]

7.9.3. Using Profiles

The procedure for using a profile to define a particular cell zone or boundary condition is outlined below.

1. Create a file that contains the desired profile, following the format described in Profile File Formats (p. 1541).

2. Read the profile using the **Read...** button in the Profiles Dialog Box (p. 4929) (Figure 7.96: The Profiles Dialog Box (p. 1548))

   or the **File/Read/Profile...** ribbon tab item.

   Setup → **Cell Zone Conditions** → **Profiles...**

   Setup → **Boundary Conditions** → **Profiles...**

   File → **Read** → **Profile...**

   Note that if you use the **Profiles** dialog box to read a file, and a profile in the file has the same name as an existing profile, the old profile will be overwritten.

3. If it is a point profile, you can choose the method of interpolation using the **Profiles** dialog box (Figure 7.96: The Profiles Dialog Box (p. 1548)):

   Setup → **Cell Zone Conditions** → **Profiles...**

   Setup → **Boundary Conditions** → **Profiles...**

   Select the point profile in the **Profile** selection list. Then select one of the three choices in the **Interpolation Method** list and click the **Apply** button. The three choices include:

   - **Constant**

     This method is zeroth-order interpolation. For each cell face at the boundary, the solver uses the value from the profile file located closest to the cell. Therefore, the accuracy of the interpol-

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ated profile will be affected by the density of the data points in your profile file. This is the default interpolation method for point profiles.

- **Inverse Distance**

  This method assigns a value to each cell face at the boundary based on weighted contributions from the values in the profile file. The weighting factor is inversely proportional to the distance between the profile point and the cell face center.

- **Least Squares**

  This method assigns values to the cell faces at the boundary through a first-order interpolation method that tries to minimizes the sum of the squares of the offsets (residuals) between the profile data points and the cell face centers. The least squares solution is found using Singular Value Decomposition (SVD).

Note:

The **Inverse Distance** and **Least Squares** profile interpolation methods are not applicable when a profile is attached to cell zones. When the cell face is outside the profile-covered zone, the Inverse Distance and Least Squares profile interpolation methods will be switched to the Constant interpolation method to improve the interpolation robustness.

For information about the interpolation methods employed for other profile types (that is, line, mesh, radial, or axial profiles), see Profile Specification Types (p. 1540).

4. You can attach a profile to a reference frame so that the profile will rotate according to the reference frame. This can be used to model the clocking effect of a rotor on a stator, for example. Under **Reference Frames**, select the reference frame to attach the chosen profile to.

5. In the boundary conditions dialog boxes (for example, the **Velocity Inlet** and **Pressure Inlet** dialog boxes), the fields defined in the profile file (and those defined in any other profile file that you have read in) will appear in the drop-down list to the right of or below each parameter for which profile specification is allowed. To use a particular profile, select it in the appropriate list.

6. Initialize the solution to interpolate the profile.

Note:

You can use a profile file or the `DEFINE_PROFILE` user-defined function to specify volumetric source terms. If you specify the source terms with a profile, you will not have access to the central coefficient of the equations solved in order to linearize the source term. You will need to use a user-defined function to do this.

For more information on UDFs, refer to the Fluent Customization Manual.

7.9.3.1. Checking and Deleting Profiles

Each profile file contains one or more profiles, and each profile has one or more fields defined in it. Once you have read in a profile file, you can check which fields are defined in each profile, and

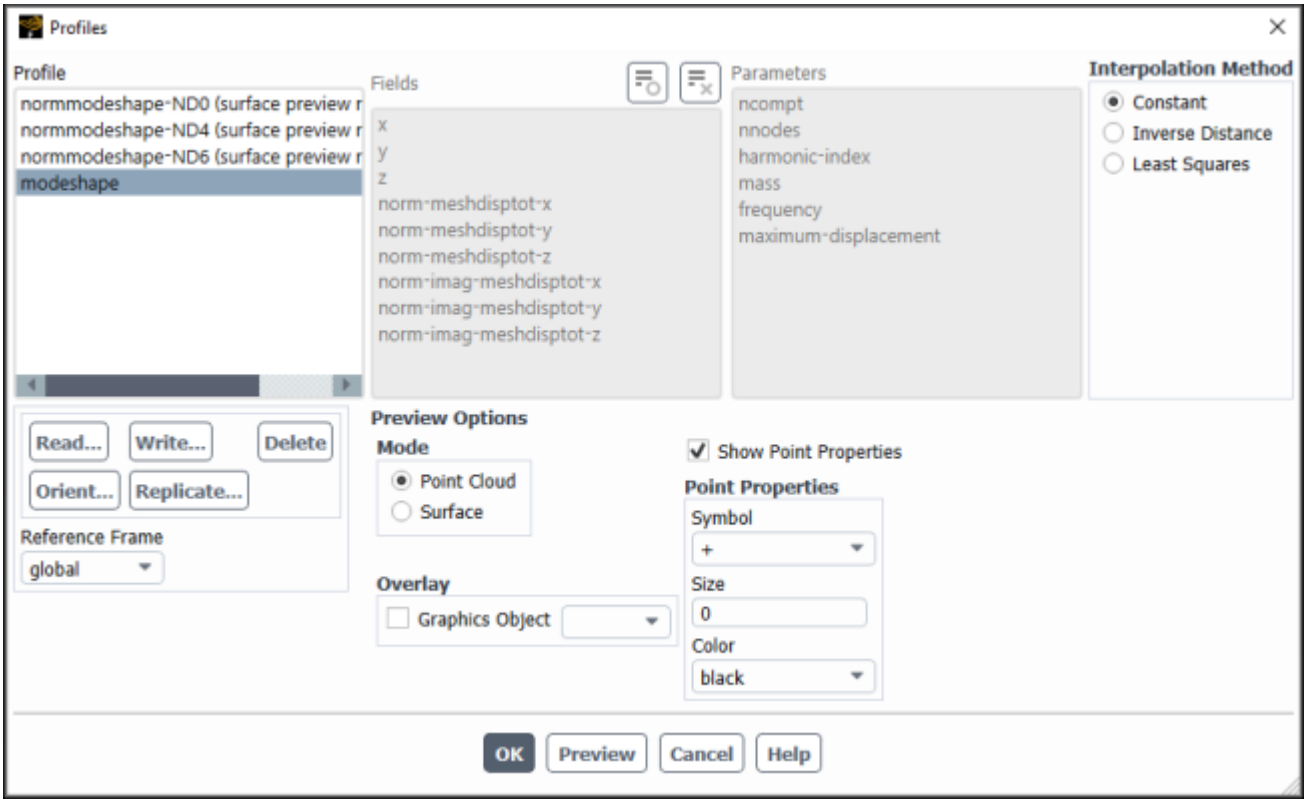
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

you can also delete a particular profile. These tasks are accomplished in the Profiles Dialog Box (p. 4929) (Figure 7.96: The Profiles Dialog Box (p. 1548)).

Setup → Cell Zone Conditions → Profiles...

Setup → Boundary Conditions → Profiles...

Figure 7.96: The Profiles Dialog Box



To check which fields are defined in a particular profile, select the profile name in the **Profile** list. The available fields in that file will be displayed in the **Fields** list. In Figure 7.96: The Profiles Dialog Box (p. 1548), the profile fields from the profile file of Example (p. 1543) are shown.

To delete a profile, select it in the **Profile** list and click the **Delete** button. When a profile is deleted, all fields defined in it will be removed from the **Fields** list.

Important:

If you are deleting a profile that is being used as an input for a boundary condition, a cell zone condition, or both, the input will be in a undefined/invalid state after deletion of the profile. To resolve this issue, you must manually update the inputs to a valid input type such as **constant**, **udf/profile**, or **expression**.

If you are deleting an existing profile to replace it with a new profile, use the following procedure:

1. Delete the existing profile.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Change the parameters defined by the existing profile to **Constant**.

3. Read the new profile and apply as desired.

7.9.3.2. Viewing Profile Data

From within Figure 7.96: The Profiles Dialog Box (p. 1548) you can preview any profile as a cloud of points. Additionally, profiles containing node-connectivity data can also be previewed as a surface (profiles that cannot be previewed as a surface are identified in parenthesis in the **Profile** list).

With either type of profile preview, you can include a mesh or contour display by enabling **Graphics Object** in the **Overlay** group box and selecting the desired graphics object from the drop-down list. See Figure 7.97: Preview of Profile as a Surface (Gray) with Mesh Overlayed (Pastel Green) (p. 1549) and Figure 7.98: Preview of Profile as a Point Cloud (Black) with Mesh Overlayed (Pastel Green) (p. 1549) for examples.

Controls for how the points appear for **Point Cloud** preview are available by enabling **Show Point Properties**.

Figure 7.97: Preview of Profile as a Surface (Gray) with Mesh Overlayed (Pastel Green)

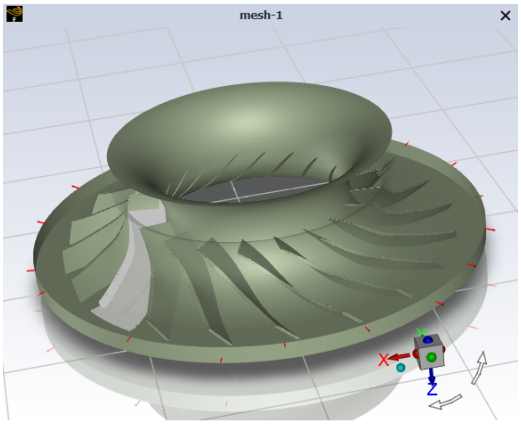


Figure 7.98: Preview of Profile as a Point Cloud (Black) with Mesh Overlayed (Pastel Green)

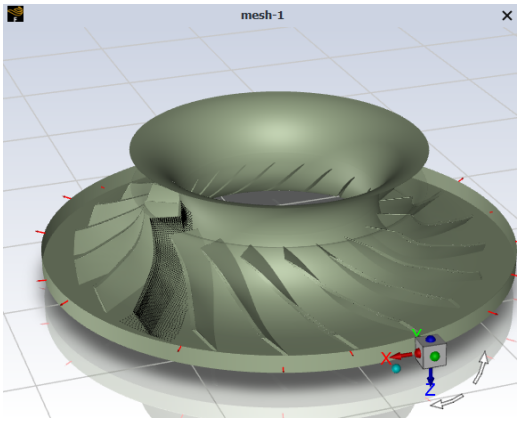


The **Plots** task page options allow you to generate XY plots of data related to profiles. You can plot the original data points from the profile file you have read into Ansys Fluent, or you can plot the

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

values assigned to the cell faces on the boundary after the profile file has been interpolated. See XY Plots of Profiles (p. 4033) for the steps to generate these plots.

You have the additional option of viewing the parameters) using the **Plot** or the **Contours** options. Note that these display options do not allow you to plot the actual values of the cell faces (as is done with the **Interpolated Data** option), because they interpolate the values stored in the adjacent cells. To view the boundary condition parameters you must first read in the profile, save a boundary condition with a profile field selected as a parameter, and initialize the flow solution. Then you can view the surface data as follows:

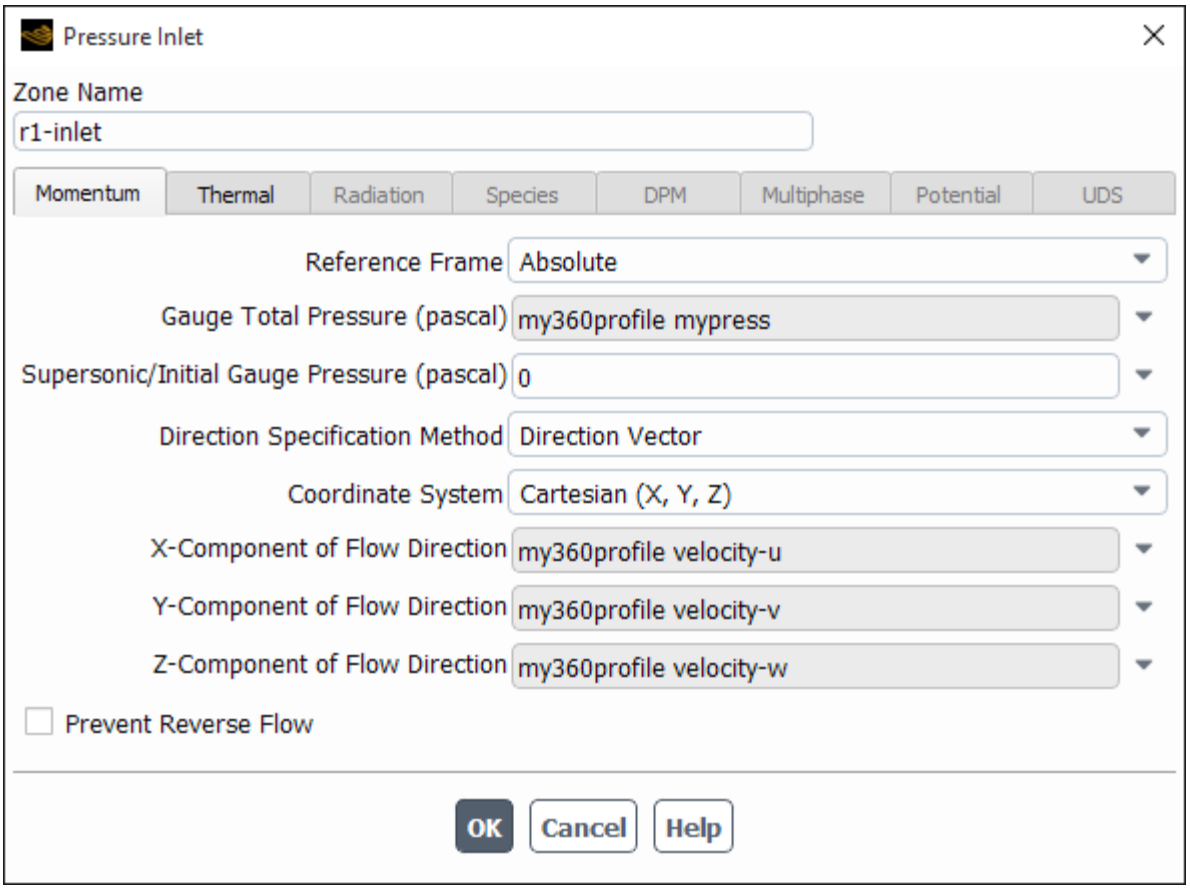
- For 2D calculations, open the **Solution XY Plot** dialog box. Select the appropriate boundary zone in the **Surfaces** list, the variable of interest in the **Y Axis Function** drop-down list, and the desired **Plot Direction**. Ensure that the **Node Values** check button is turned on, and then click **Plot**. You should then see the profile plotted. If the data plotted does not agree with your specified profile, this means that there is an error in the profile file.
- For 3D calculations, use the **Contours** dialog box to display contours on the appropriate boundary zone surface. The **Node Values** check button must be turned on in order for you to view the profile data. If the data shown in the contour plot does not agree with your specified profile, this means that there is an error in the profile file.

7.9.3.3. Example

In Figure 7.99: Example of Using Profiles as Boundary Conditions (p. 1551), profiles are used to specify the gauge total pressure and the x, y, z flow direction components at a pressure inlet boundary.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.99: Example of Using Profiles as Boundary Conditions



7.9.3.4. Reorienting Profiles

For 3D cases only, Ansys Fluent allows you to change the orientation of an existing profile so that it can be used at a boundary positioned arbitrarily in space. This allows you, for example, to take experimental data for an inlet with one orientation and apply it to an inlet in your model that has a different spatial orientation. Note that Ansys Fluent assumes that the profile and the boundary are planar.

7.9.3.4.1. Steps for Changing the Profile Orientation

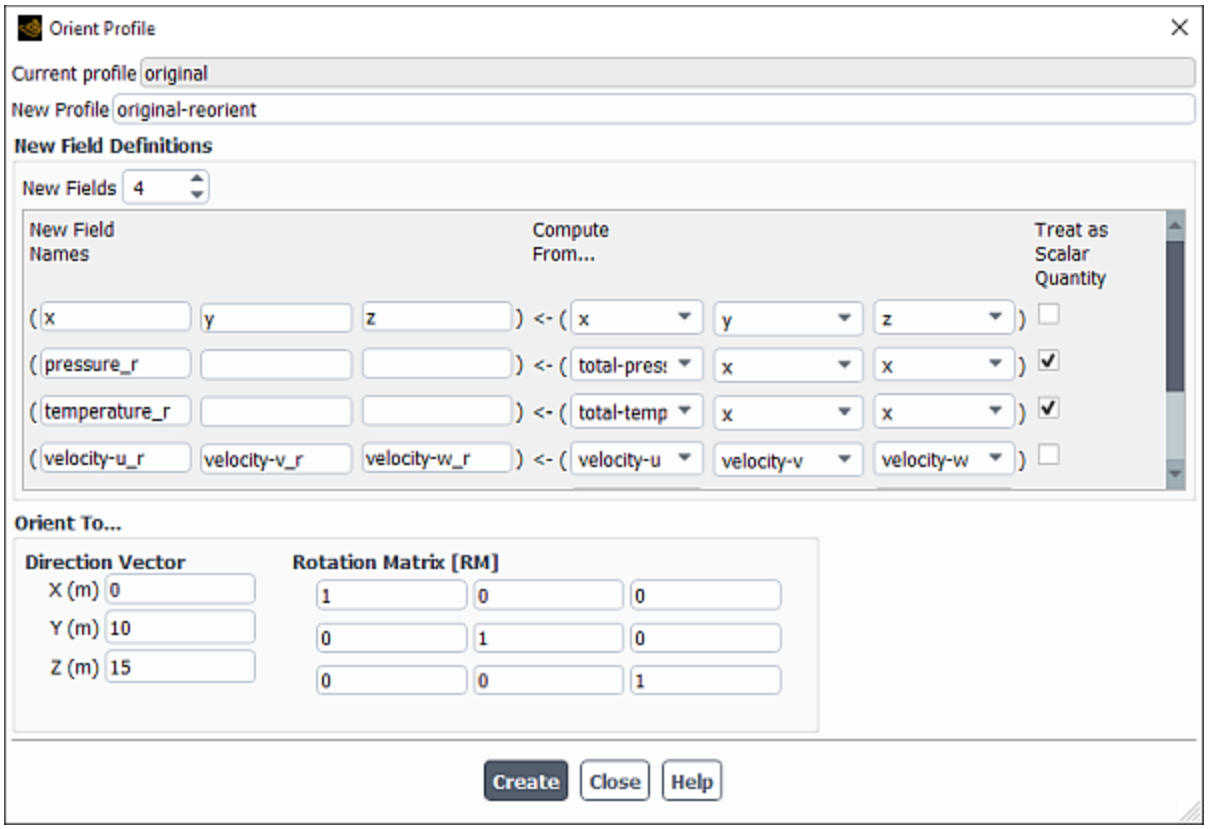
The procedure for orienting the profile data in the principal directions of a boundary is outlined below:

1. Define and read the profile as described in Using Profiles (p. 1546).

2. In the Profiles Dialog Box (p. 4929), select the profile in the **Profile** list, and then click the **Orient...** button. This will open the Orient Profile Dialog Box (p. 4934) (Figure 7.100: The Orient Profile Dialog Box (p. 1552)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.100: The Orient Profile Dialog Box



3. In the **Orient Profile** dialog box, enter the name of the new profile you want to create in the **New Profile** box.

4. Specify the number of fields you want to create using the up/down arrows next to the **New Fields** box. The number of new fields is equal to the number of vectors and scalars to be defined plus 1 (for the coordinates).

5. Define the coordinate field.

   a. Enter the names of the three coordinates (x, y, z) in the first row under **New Field Names**.

   Important:

   Ensure that the coordinates are named x, y, and z only. Do not use any other names or upper case letters in this field.

   b. Select the appropriate local coordinate fields for x, y, and z from the drop-down lists under **Compute From...**. (A selection of **0** indicates that the coordinate does not exist in the original profile; that is, the original profile was defined in 2D.)

6. Define the vector fields in the new profile.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

a. Enter the names of the 3 components in the directions of the coordinate axes of the boundary under **New Field Names**.

> **Important:**
>
> Do not use upper case letters in these fields.

b. Select the names of the 3 components of the vector in the local x, y, and z directions of the profile from the drop-down lists under **Compute From...**.

7. Define the scalar fields in the new profile.

a. Enter the name of the scalar in the first column under **New Field Names**.

> **Important:**
>
> Do not use upper case letters in these fields.

b. Click the button under **Treat as Scalar Quantity** in the same row.

c. Select the name of the scalar in the corresponding drop-down list under **Compute From...**.

8. Under **Orient To...**, specify the rotational matrix RM under the **Rotation Matrix [RM]**. The rotational matrix used here is based on Euler angles (γ, β, and α) that define an orthogonal system $x'y'z'$ as the result of the three successive rotations from the original system xyz. That is,

$$\begin{bmatrix} x' \\ y' \\ z' \end{bmatrix} = [RM] \begin{bmatrix} x \\ y \\ z \end{bmatrix} \tag{7.210}$$

$$RM = [C][B][A] \tag{7.211}$$

where C, B, and A are the successive rotations around the z, y, and x axes, respectively.

Rotation around the z axis:

$$C = \begin{bmatrix} \cos\gamma & -\sin\gamma & 0 \\ \sin\gamma & \cos\gamma & 0 \\ 0 & 0 & 1 \end{bmatrix} \tag{7.212}$$

Rotation around the y axis:

$$B = \begin{bmatrix} \cos\beta & 0 & \sin\beta \\ 0 & 1 & 0 \\ -\sin\beta & 0 & \cos\beta \end{bmatrix} \tag{7.213}$$

Rotation around the x axis:

$$A = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\alpha & -\sin\alpha \\ 0 & \sin\alpha & \cos\alpha \end{bmatrix} \tag{7.214}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

9. Under **Orient To...**, specify the **Direction Vector**. The **Direction Vector** is the vector that translates a profile to the new position, and is defined between the centers of the profile fields.

   Important:

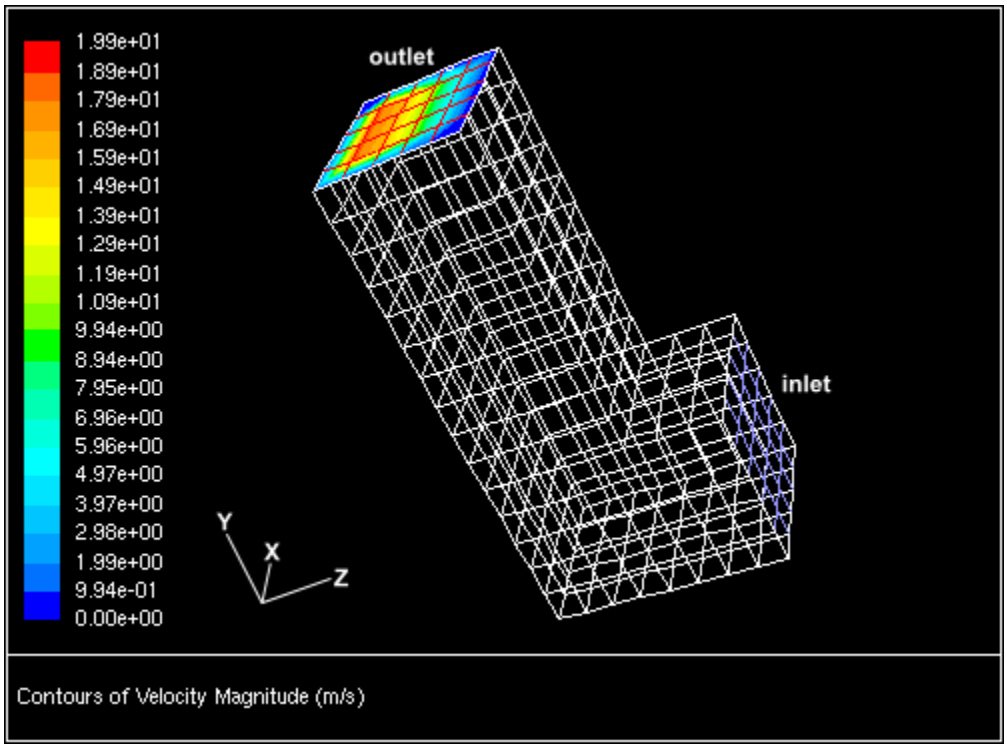
   Note that depending on your case, it may be necessary to perform only a rotation, only a translation, or a combination of a translation and a rotation.

10. Click the **Create** button in the **Orient Profile** dialog box, and your new profile will be created. Its name, which you entered in the **New Profile** box, will now appear in the **Profiles** dialog box and will be available for use at the desired boundary.

7.9.3.4.2. Profile Orienting Example

Consider the domain with a square inlet and outlet, shown in Figure 7.101: Scalar Profile at the Outlet (p. 1554). A scalar profile at the outlet is written out to a profile file. The purpose of this example is to impose this outlet profile on the inlet boundary via a 90 $^{\circ}$ rotation about the x axis. However, the rotation will locate the profile away from the inlet boundary. To align the profile to the inlet boundary, a translation via a directional vector must be performed.

Figure 7.101: Scalar Profile at the Outlet



The problem is shown schematically in Figure 7.102: Problem Specification (p. 1556). Φ_{out} is the scalar profile of the outlet. $\Phi_{out}^{'}$ is the image of the Φ_{out} rotated 90 $^{\circ}$ around the x axis. In this example, since $\gamma=\beta=0$, then $C=B=I$, where I is the identity matrix, and the rotation matrix is

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$RM=[C][B][A]=\begin{bmatrix}1 & 0 & 0\\ 0 & \cos 90^{\circ} & -\sin 90^{\circ}\\ 0 & \sin 90^{\circ} & \cos 90^{\circ}\end{bmatrix}=\begin{bmatrix}1 & 0 & 0\\ 0 & 0 & -1\\ 0 & 1 & 0\end{bmatrix} \tag{7.215}$$

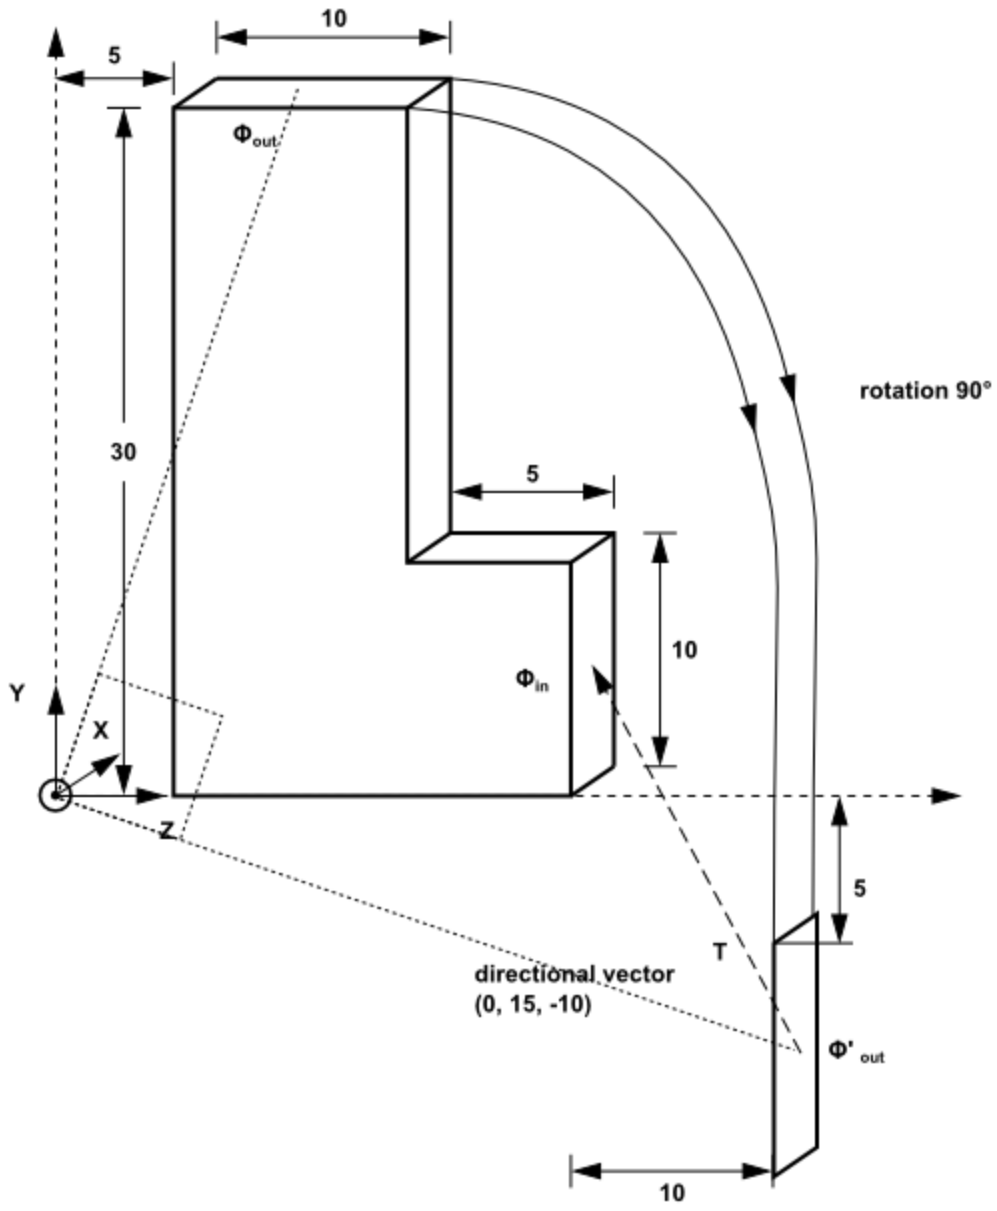
To overlay the outlet profile on the inlet boundary, a translation will be performed.

To overlay the outlet profile on the inlet boundary, a translation will be performed. The directional vector is the vector that translates Φ'_{out} to Φ_{in}. In this example, the directional vector is $(0,15,-10)^{T}$. The appropriate inputs for the **Orient Profile** dialog box are shown in Figure 7.100: The Orient Profile Dialog Box (p. 1552).

Note that if the profile being imposed on the inlet boundary was due to a rotation of -90 ° about the x axis, then the rotational matrix RM must be found for $\gamma=\beta=0$ and $\alpha=-90^{\circ}$, and a new directional vector must be found to align the profile to the boundary.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.102: Problem Specification



7.9.3.5. Replicating Profiles

In many turbomachinery cases, a profile can be obtained from an initial small-scale simulation (often one passage but sometimes more) and then applied to a larger, often full 360 degree, simulation. Replicating a profile enables you to copy the initial profile periodically for use in a larger simulation.

The following topics are discussed:

7.9.3.5.1. Steps for Replicating a Profile

7.9.3.5.2. Complex Mode Shape Profile Replication

7.9.3.5.1. Steps for Replicating a Profile

The procedure for replicating the profile data periodically is outlined below:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Define and read the profile as described in Using Profiles (p. 1546).

2. Open the **Profiles** dialog box.

   Physics → **Zones** → **Profiles...**

3. Select the profile to replicate and click **Replicate...** to open the **Replicate Profile** dialog box (Figure 7.103: The Replicate Profile Dialog Box (p. 1557)).

Figure 7.103: The Replicate Profile Dialog Box

   a. Enter a name in the **New Profile** field (for the expanded profile name).

   b. If the profile contains mesh displacement field variables (variables containing the `mesh-disp`, `meshdisptot` keyword), the **Autofill** button becomes available. Upon clicking **Autofill**, Fluent will automatically fill the dialog box based on the current profile. Otherwise, you can follow the steps below to specify profile replication manually.

   c. Specify the number of fields you want to create using the up/down arrows next to the **New Fields** box. The number of new fields is equal to the number of vectors and scalars to be defined plus 1 (including the coordinates).

   d. Define the coordinate field.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

i. Enter the names of the three coordinates (x, y, z) in the first row under **New Field Names**.

> **Important:**
>
> Ensure that the coordinates are named x, y, and z only. Do not use any other names or upper case letters in this field.

ii. Select the appropriate local coordinate fields for x, y, and z from the drop-down lists under **Compute From...**. (A selection of **0** indicates that the coordinate does not exist in the original profile; that is, the original profile was defined in 2D.)

e. Define the vector fields in the new profile.

i. Enter the names of the 3 components in the directions of the coordinate axes under **New Field Names**.

> **Important:**
>
> Do not use upper case letters in these fields.

ii. Select the names of the 3 components of the vector in the local coordinates of the profile from the drop-down lists under **Compute From...**.

f. Define the scalar fields in the new profile.

i. Enter the name of the scalar in the first column under **New Field Names**.

> **Important:**
>
> Do not use upper case letters in these fields.

ii. Select **Treat as Scalar Quantity** in the same row.

iii. Select the name of the scalar in the corresponding drop-down list under **Compute From...**.

4. Specify the replication settings in the **Current Profile Definitions** group box.

a. If you are creating a full 360 degree profile, select **Full 360 deg.**. Fluent automatically determines the number of copies of the original profile that are needed to make the full 360 degree profile based on the other information you specify.

b. If you did not select **Full 360 deg.**, you must specify the **Number of copies** to manually determine how many copies of the original profile are created.

c. The **Number of sectors in 360 deg.** is the number of periodic sections, based on the original profile, that are present in 360 degrees.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

d. The **Number of sectors in profile** is the number of periodic sections in the original profile.

e. The **Calculated angle** is for display only and is the angle occupied by the original profile. When using the **Full 360 deg.** option, you can determine the number of copies that are created by dividing 360 by the **Calculated angle**.

f. Specify the **Rotation-Axis Direction**. This is the **X**, **Y**, and **Z** components of the axis about which the selected profile is replicated.

5. Optionally, you can select **Include Sector Tag** and Fluent will append a sector tag column onto the replicated profile to indicate the original and replicated profiles. The numbering follows the right hand rule applied to the **Rotation-Axis Direction** that you have specified.

6. Click the **Create** button in the **Replicate Profile** dialog box, and your new profile will be created. Its name, which you entered in the **New Profile** box, will now appear in the **Profiles** dialog box and will be available for use at the desired boundary.

7.9.3.5.2. Complex Mode Shape Profile Replication

Complex mode shapes are composed of a real and an imaginary vector pair that cannot be replicated (expanded) separately in the same way as is done for other profiles with real-only vectors.

The process of complex mode shape replication is performed as follows:

1. The real and imaginary components are phase-shifted:

$$\begin{aligned} \left|\vec{X}\right| &= \sqrt{R^2+I^2} \\ \phi &= 2k\pi\frac{ND}{N_{360}} + \arctan\left(\frac{I}{R}\right) \\ R^* &= \left|\vec{X}\right|\cos(\phi) \\ I^* &= \left|\vec{X}\right|\sin(\phi) \end{aligned} \tag{7.216}$$

2. The shifted components are then rotated to the passage k:

$$\begin{aligned} R^k &= R^* \cdot [M] \\ I^k &= I^* \cdot [M] \end{aligned} \tag{7.217}$$

Where the rotation matrix is $[M]$ and computed with a given rotation axis (u,v,w) as:

Note:

The rotation matrix is computed in the same way as for non-complex mode shape replication.

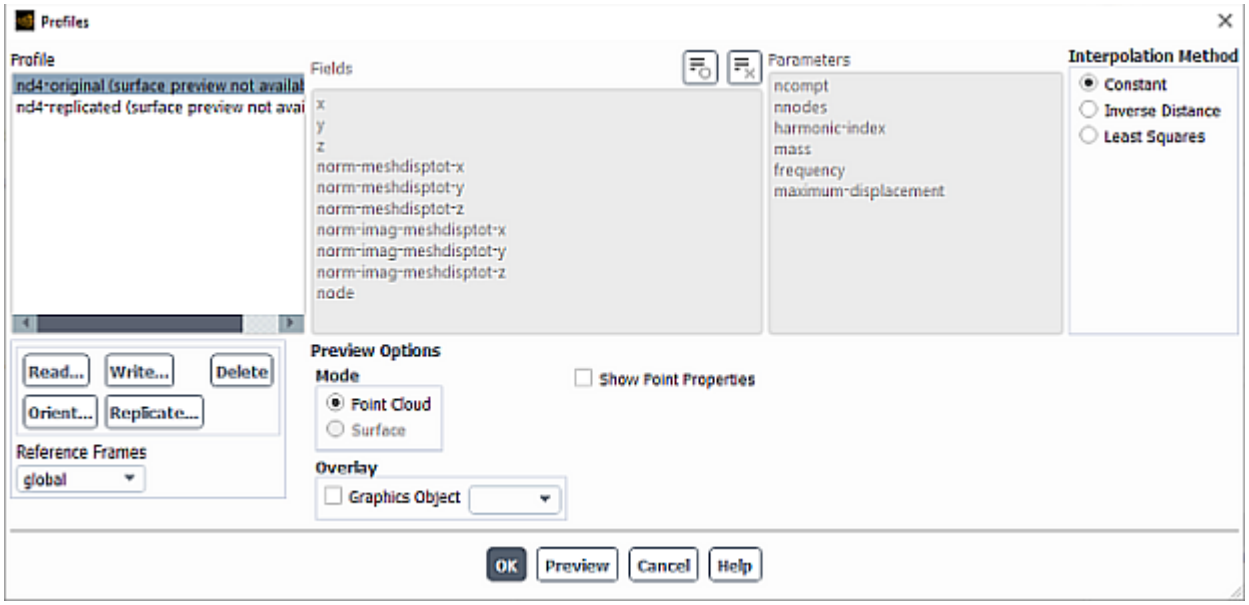
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$
\begin{aligned}
&\varphi = 2k\pi \frac{N_{component}}{N_{360}} \\
&M[0][0] = \cos(\varphi) + u*u*(1-\cos(\varphi)) \\
&M[0][1] = u*v*(1-\cos(\varphi)) - w*\sin(\varphi) \\
&M[0][2] = u*w*(1-\cos(\varphi)) - v*\sin(\varphi) \\
&M[1][0] = v*u*(1-\cos(\varphi)) - w*\sin(\varphi) \\
&M[1][1] = \cos(\varphi) + v*v*(1-\cos(\varphi)) \\
&M[1][2] = v*w*(1-\cos(\varphi)) - u*\sin(\varphi) \\
&M[2][0] = w*u*(1-\cos(\varphi)) - v*\sin(\varphi) \\
&M[2][1] = w*v*(1-\cos(\varphi)) - u*\sin(\varphi) \\
&M[2][2] = \cos(\varphi) + w*w*(1-\cos(\varphi))
\end{aligned}
\tag{7.218}
$$

7.9.3.5.2.1. Steps for Replicating a Complex Mode Shape Profile

After opening the **Replicate Profile** dialog box, as described in Replicating Profiles (p. 1556), Fluent detects the presence of a parameter called `harmonic index` as shown in Figure 7.104: The Profiles Dialog Box with Complex Mode Shape Profile (p. 1560). This parameter must be correctly defined for Fluent to accurately expand the complex mode shape. Note that the harmonic index parameter is automatically included in profiles generated in Ansys Mechanical for cases with Cyclic Symmetry. If the profile was created with a source outside of the Ansys environment, you are responsible for creating the parameter and setting it to the correct value.

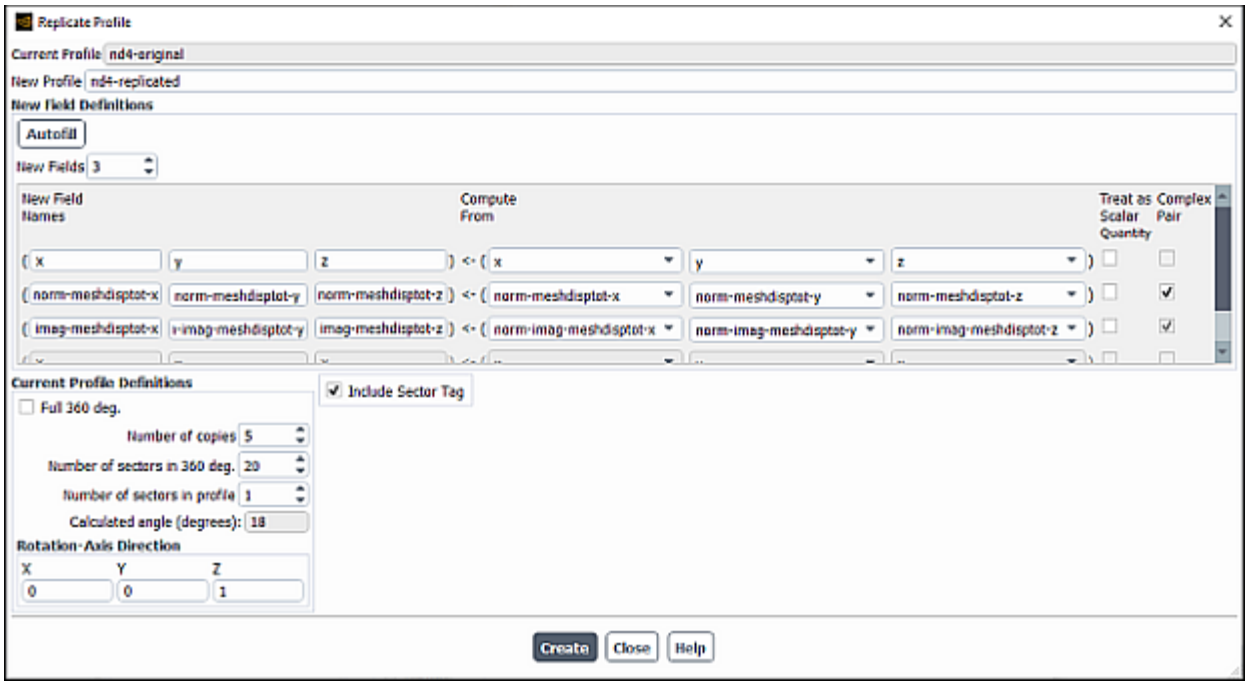
Figure 7.104: The Profiles Dialog Box with Complex Mode Shape Profile



With the presence of the `harmonic index` parameter, the **Replicate Profile** dialog box has an additional column of checkboxes named **Complex Pair**. Selecting the **Complex Pair** checkbox indicates the rows corresponding to the real and imaginary vector pairs of the complex mode shape, as shown in Figure 7.105: The Replicate Profile Dialog Box with Complex Pair (p. 1561).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.105: The Replicate Profile Dialog Box with Complex Pair



The workflow for expanding a complex mode shape is as follows:

1. Load a profile that contains a parameter named `harmonic index`. For details on loading a profile, see Using Profiles (p. 1546).

2. If the profile contains mesh displacement field variables (variables containing the `mesh-disp`, `meshdisptot` keyword), the **Autofill** button becomes available. Upon clicking **Autofill**, Fluent will automatically fill the dialog box based on the current profile. Otherwise, you can follow the steps below to specify profile replication manually.

3. Enter the real vector component of the complex mode shape into any row and select **Complex Pair**. This indicates to Fluent that it is the first part of the complex pair, and that the imaginary vector will immediately follow on the next row.

   The real and complex pairs can be defined in any new field row. However, the real vector component must be defined first, followed by the imaginary vector on the immediate row below the real vector.

4. When the **Complex Pair** checkbox is selected, the immediate following row will also be set in anticipation of the imaginary vector components being defined. Enter the imaginary vector components in the second row.

   Note:

   When the **Complex Pair** checkboxes are set, all other checkboxes in that column will be greyed out to prevent another pair from being defined. This is a current limitation that only one complex pair can be defined.

5. Complete the rest of the dialog box as described in Steps for Replicating a Profile (p. 1556)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.10. Coupling Boundary Conditions with GT-POWER

GT-POWER users can define time-dependent boundary conditions in Ansys Fluent based on information from GT-POWER. During the Ansys Fluent simulation, Ansys Fluent and GT-POWER are coupled together and information about the boundary conditions at each time step is transferred between them.

7.10.1. Requirements and Restrictions

7.10.2. User Inputs

7.10.3. Torque-Speed Coupling with GT-POWER

7.10.1. Requirements and Restrictions

Note the following requirements and restrictions for the GT-POWER coupling:

- The flow must be unsteady.
- The compressible ideal gas law must be used for density.
- Each boundary zone for which you plan to define conditions using GT-POWER must be a boundary of one of the following types:
  - velocity inlet
  - mass-flow inlet
  - pressure inlet
  - pressure outlet
  - wall (for details, see Torque-Speed Coupling with GT-POWER (p. 1566))

  Also, a maximum of 20 boundary zones can be coupled to GT-POWER.
- Fluent checks the area of the 1D coupled boundary as calculated by Fluent and GT-POWER to ensure the calculated areas differ by no more than 5%. When the difference is more than 5%, Fluent stops with an error message and displays the two areas.
- If a mass-flow inlet or pressure inlet is coupled to GT-POWER, you must select **Normal to Boundary** as the **Direction Specification Method** in the **Mass-Flow Inlet** or **Pressure Inlet** dialog box. For a velocity inlet, you must select **Magnitude, Normal to Boundary** as the **Velocity Specification Method** in the **Velocity Inlet** dialog box.
- The mass flow specification method in the **Mass-Flow Inlet** boundary has to always be **Mass Flux** and not **Mass Flow Rate** when coupling with GTPower.
- Boundary conditions for the following variables can be obtained from GT-POWER:
  - velocity
  - temperature
  - pressure

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

  - density
  - species mass fractions
  - k and ε (Note that it is recommended that you define these conditions in Ansys Fluent yourself, rather than using the data provided by GT-POWER, since the GT-POWER values are based on a 1D model.)

- Make sure that the material properties you set in Ansys Fluent are the same as those used in GT-POWER, so that the boundary conditions will be valid for your coupled simulation.
- If your model includes species, make sure that the name of each species in GT-POWER corresponds to the **Chemical Formula** for that species material in the **Materials** dialog box. Also, recall that Ansys Fluent can handle a maximum of 50 species.
- You can install the GT-POWER libraries in a directory other than the default location. If the GT-POWER libraries are loaded into a non-default location, you need to set the following environment variables:
  - `Fluent_GTIHOME` — the GTI installation directory where GT-POWER is installed
  - `Fluent_GTIVERSION` — the current version of the GTI installation

  Important:

  GTI is not backwards compatible.

7.10.2. User Inputs

The procedure for setting up the GT-POWER coupling in Ansys Fluent is presented below.

1. Read in the mesh file and define the models, materials, and boundary zone types (but *not* the actual boundary conditions), noting the requirements and restrictions listed in Requirements and Restrictions (p. 1562).
2. Specify the location of the GT-POWER data and have Ansys Fluent use them to generate user-defined functions for the relevant boundary conditions (using the 1D Simulation Library Dialog Box (p. 5332), shown in Figure 7.106: The 1D Simulation Library Dialog Box (p. 1564)).

   User Defined → **Model Specific** → **1D Coupling...**

Figure 7.106: The 1D Simulation Library Dialog Box

a. Select **GTpower** in the **1D Library** drop-down list.

b. Specify the name of the GT-POWER input file in the **1D Input File Name** field.

c. Click the **Start** button.

When you click **Start**, GT-POWER will start up and Ansys Fluent user-defined functions for each boundary in the input file will be generated.

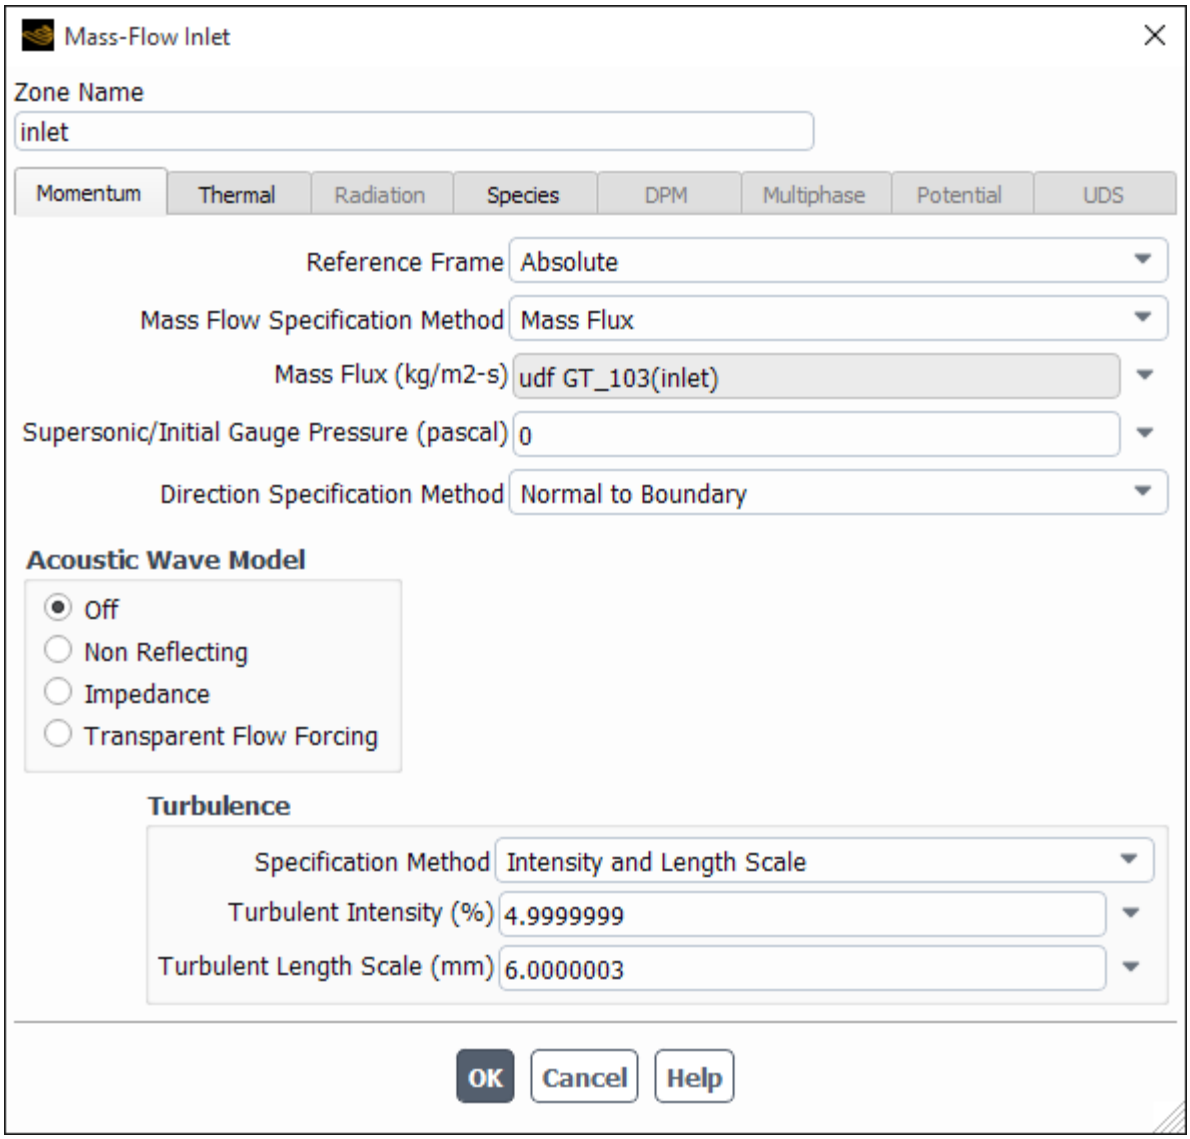
3. Set boundary conditions for all zones. For flow boundaries for which you are using GT-POWER data, select the appropriate UDFs as the conditions.

Important:

Note that you must select the same UDF for all conditions at a particular boundary zone (as shown, for example, in Figure 7.107: Using GT-POWER Data for Boundary Conditions (p. 1565)); this UDF contains all of the conditions at that boundary.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 7.107: Using GT-POWER Data for Boundary Conditions



4. If you plan to continue the simulation at a later time, starting from the final data file of the current simulation, specify how often you want to have the case and data files saved automatically.

   Solution → Calculation Activities (Autosave Case/Data) → Edit...

   To use a GT-POWER restart file to restart an Ansys Fluent calculation, you must edit the GT-POWER input data file. See the GT-POWER User's Guide for instructions.

5. Continue the problem setup and calculate a solution in the usual manner.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7.10.3. Torque-Speed Coupling with GT-POWER

Torque-speed coupling with GT-POWER is a unique case in which Fluent receives shaft speed from GT-POWER and returns torque. The procedure differs from the typical coupling between GT-Power and Fluent, and is as follows:

Important:

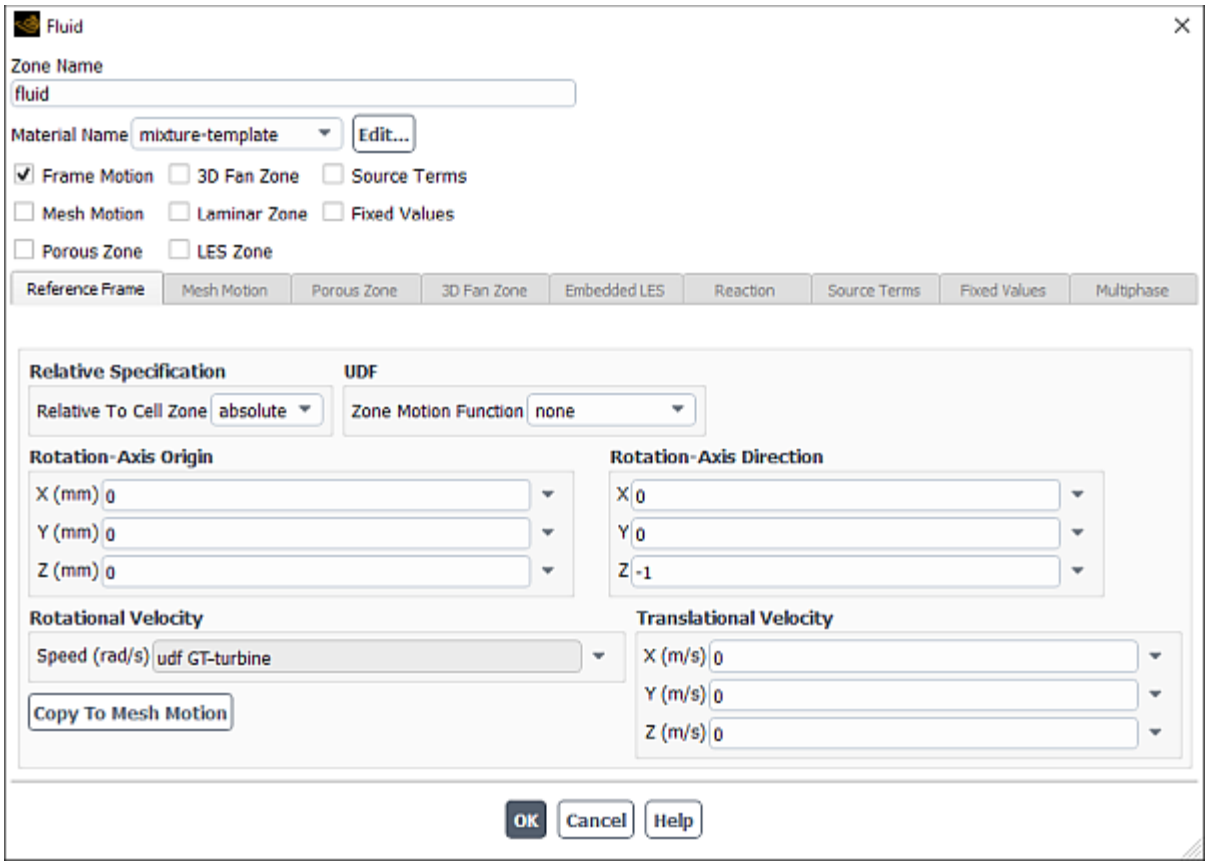
You must be using GT-POWER v2017.2 or greater to perform torque-speed coupling with Ansys Fluent.

---

1. Complete steps 1 and 2 in the above section on User Inputs (p. 1563). The `.dat.h5` file should have at least one turbo-machine exposed to complete the coupling.

2. Enable **Frame Motion** in the cell zone that is receiving shaft speed from GT-Power. You must also select the appropriate UDF for **Rotational Velocity**. The UDF must correspond to the turbo-machine exposed from GT-POWER ("turbine", in the example shown below).

Figure 7.108: Cell Zone Conditions for Torque-Speed Coupling with GT-POWER



3. Specify a **Wall** boundary on which the torque is calculated and transferred to GT-POWER. The following requirements apply:

   - The wall boundary must be attached to the rotating cell zone from step 2, to receive the shaft speed from GT-POWER.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The name of the wall boundary must be the same as the turbo-machine it is coupled with ("turbine", in the case presented above).

During the solution, shaft speed is obtained from GT-POWER at every time-step, with Fluent calculating and returning torque within each time-step as well.

7.11. Coupling Boundary Conditions with WAVE

WAVE users can define time-dependent boundary conditions in Ansys Fluent based on information from WAVE. During the Ansys Fluent simulation, Ansys Fluent and WAVE are coupled together and information about the boundary conditions at each time step is transferred between them.

7.11.1. Requirements and Restrictions

7.11.2. User Inputs

7.11.1. Requirements and Restrictions

Note the following requirements and restrictions for the WAVE coupling:

- WAVE must be installed and licensed.
- There are always five species that must be modeled in Ansys Fluent just as they are defined in WAVE (F1, F2, F3, F4, and F5). It is recommended that realistic material properties be assigned to each of the five species.
- The flow must be unsteady.
- The compressible ideal gas law must be used for density.
- Each boundary zone for which you plan to define conditions using WAVE must be a flow boundary of one of the following types:
  - velocity inlet
  - mass-flow inlet
  - pressure inlet
  - pressure outlet

  Also, a maximum of 20 boundary zones can be coupled to WAVE.
- If a mass-flow inlet or pressure inlet is coupled to WAVE, you must select **Normal to Boundary** as the **Direction Specification Method** in the **Mass-Flow Inlet** or **Pressure Inlet** Dialog Box. For a velocity inlet, you must select **Magnitude, Normal to Boundary** as the **Velocity Specification Method** in the **Velocity Inlet** Dialog Box.
- Boundary conditions for the following variables can be obtained from WAVE:
  - velocity
  - temperature

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

  - pressure
  - density
  - species mass fractions
  - k and ε (Note that you are required to define these conditions in Ansys Fluent yourself, since WAVE does not calculate them.)

- Make sure that the material properties you set in Ansys Fluent are the same as those used in WAVE, so that the boundary conditions will be valid for your coupled simulation.
- If your model includes species, make sure that the name of each species in WAVE corresponds to the **Chemical Formula** for that species material in the **Create/Edit Materials** dialog box. Also, recall that Ansys Fluent can handle a maximum of 50 species.

7.11.2. User Inputs

The procedure for setting up the WAVE coupling in Ansys Fluent is presented below.

1. Read in the mesh file and define the models, materials, and boundary zone types.
2. Specify the location of the WAVE data and have Ansys Fluent use them to generate user-defined functions for the relevant boundary conditions (using the 1D Simulation Library Dialog Box (p. 5332), shown in Figure 7.109: The 1D Simulation Library Dialog Box with WAVE Selected (p. 1568)).

   User Defined → Model Specific → 1D Coupling...

   Figure 7.109: The 1D Simulation Library Dialog Box with WAVE Selected

   
   a. Select **WAVE** in the **1D Library** drop-down list.

   b. Specify the name of the WAVE input file in the **1D Input File Name** field.

   c. Click the **Start** button.

   When you click **Start**, WAVE will start up and Ansys Fluent user-defined functions for each boundary in the input file will be generated.

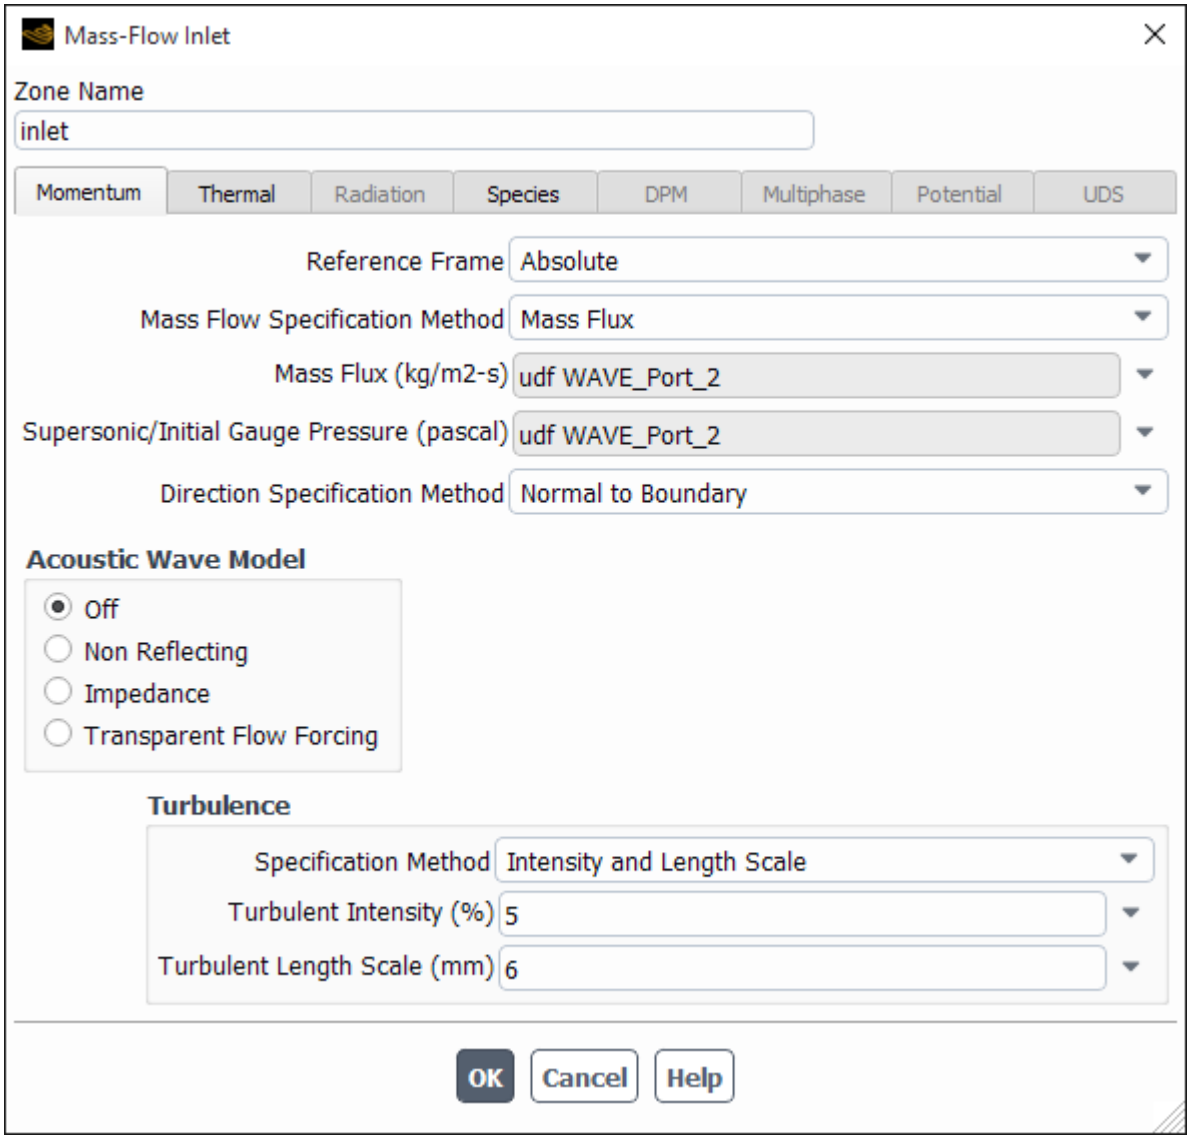
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Set boundary conditions for all zones. For flow boundaries for which you are using WAVE data, select the appropriate UDFs as the conditions.

Important:

Note that you must select the same UDF for all conditions at a particular boundary zone (as shown, for example, in Figure 7.110: Using WAVE Data for Boundary Conditions (p. 1569)); this UDF contains all of the conditions at that boundary.

Figure 7.110: Using WAVE Data for Boundary Conditions



4. If you plan to continue the simulation at a later time, restarting from the final data file of the current simulation, you need to instruct both Ansys Fluent and WAVE how often that you want to automatically save your data. You should instruct Ansys Fluent to automatically save case and data files at specified intervals using the autosave feature.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Solution → Calculation Activities → Autosave On

In addition, you should instruct WAVE as to how often it should generate its own restart files. See the WAVE User's Guide for instructions on this feature.

Important:

To use the restart feature, the time interval for writing data files must be set to the same value in both Ansys Fluent and WAVE. For example, if Ansys Fluent has set the autosave feature to 100, then WAVE must also set the restart file write frequency to 100 as well.

5. Continue the problem setup and calculate a solution in the usual manner.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Chapter 8: Physical Properties

This chapter describes how to define materials, the physical equations used to compute material properties, and the methods you can use for each property input. Each property is described in detail in the following sections. If you are using one of the general multiphase models (VOF, mixture, or Eulerian), see Defining the Phases (p. 2928) for information about how to define the individual phases and their material properties.

8.1. Defining Materials

8.2. Defining Properties Using Temperature-Dependent Functions

8.3. Density

8.4. Viscosity

8.5. Thermal Conductivity

8.6. User-Defined Scalar (UDS) Diffusivity

8.7. Specific Heat Capacity

8.8. Radiation Properties

8.9. Mass Diffusion Coefficients

8.10. Standard State Enthalpies

8.11. Standard State Entropies

8.12. Unburnt Thermal Diffusivity

8.13. Kinetic Theory Parameters

8.14. Operating Pressure

8.15. Using a Reference Pressure to Adjust the Gauge Pressure Field

8.16. Real Gas Models

8.1. Defining Materials

An important step in the setup of the model is to define the materials and their physical properties. Material properties are defined using either the Materials Task Page (p. 4831) or the **Materials** tree branch, where you can enter values for the properties that are relevant to the problem scope you have defined in the Models Task Page (p. 4644). These properties may include the following:

- density and/or molecular weights
- viscosity
- heat capacity
- thermal conductivity
- UDS diffusion coefficients

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- mass diffusion coefficients
- standard state enthalpies
- kinetic theory parameters

Properties may be temperature-dependent and/or composition-dependent, with temperature dependence based on a polynomial, piecewise-linear, or piecewise-polynomial function and individual component properties either defined by you or computed via kinetic theory.

The Materials Task Page (p. 4831) will show the properties that need to be defined for the active physical models. If any property you define requires the energy equation to be solved (for example, ideal gas law for density, temperature-dependent profile for viscosity), Ansys Fluent will automatically enable the energy equation. Then you have to define the thermal boundary conditions and other parameters yourself.

For additional information, see the following sections:

8.1.1. Physical Properties for Solid Materials
8.1.2. Material Types and Databases
8.1.3. Using the Create/Edit Materials Dialog Box
8.1.4. Using a User-Defined Materials Database

8.1.1. Physical Properties for Solid Materials

For solid materials, only density, thermal conductivity, and heat capacity are defined. If you are modeling semi-transparent media, then radiation properties are also defined. You can specify a constant value, a temperature-dependent function, or a user-defined function for thermal conductivity; a constant value or temperature-dependent function for heat capacity; and a constant value for density.

If you are using the pressure-based solver, density and heat capacity for a solid material are not required unless you are modeling transient flow or moving solid zones. Heat capacity will appear in the list of solid properties for steady flows as well. The value will be used just for postprocessing enthalpy; not in the calculation.

8.1.2. Material Types and Databases

In Ansys Fluent, you can define six types of materials: fluids, solids, mixtures, combusting-particles, droplet-particles, and inert-particles. Physical properties of fluids and solids are associated with named material; these materials are then assigned as boundary conditions for zones.

When you model species transport, define a mixture material, consisting of the various species involved in the problem. Properties will be defined for the mixture, as well as for the constituent species, which are fluid materials. The mixture material concept is discussed in detail in Mixture Materials (p. 2355). Combusting-particles, droplet-particles, and inert-particles are available for the discrete-phase model, as described in The Concept of Discrete-Phase Materials (p. 2811).

Ansys Fluent provides the following built-in databases:

- A built-in global database of approximately 675 predefined materials along with their properties and default values for each property. To define a material in the problem setup, you can copy

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

materials from this global (site-wide) database and use the default properties or define new materials by editing their properties. The Ansys Fluent materials database is located in the following file:

path `/ansys_inc/v241/fluent/fluent24.1.0/cortex/lib/propdb.scm`

where *path* is the directory in which you installed Ansys Fluent.

- A built-in database of more than 700 predefined solid materials with properties from the Ansys GRANTA Materials Data for Simulation (GRANTA MDS). A separate license is required for copying materials from the GRANTA MDS Database into the problem setup. Materials from the GRANTA MDS Database can be used in the same way as materials from the Ansys Fluent materials database.
- A GRANTA MDS license is held for 30 minutes or until the program is closed, whichever is the sooner. Subsequent accesses of MDS data resets the timer. When no MDS license is available, only the description of the selected material will be displayed, but not its properties. The copy operation will abort with an information message.

In addition to using the Ansys Fluent material database, you can also create your own database and materials, and use it to define the materials in your problem setup. See Using a User-Defined Materials Database (p. 1581) for information about creating and using user-defined custom material databases.

Important:

- All the materials in your local materials list will be saved in the case file (when you write one). The materials specified by you will be available to you if you read this case file into a new solver session.
- A material may co-exist as a pure substance fluid as well as a species in one or multiple mixture materials. The pure fluid and the species for each mixture are separate objects and may have independent property settings. *Therefore, editing the properties of the pure fluid will not modify the same properties for that fluid included in the mixture. If you intend to modify some material properties, you can make a copy of the pure fluid, and rename it. Using the copy in the mixture makes it easier to understand which version of the fluid is being modified.*

8.1.3. Using the Create/Edit Materials Dialog Box

The Create/Edit Materials Dialog Box (p. 4833) allows you to define the materials and their properties in your problem setup using either the **Fluent Database** or a **User-Defined Database**. It enables you to copy materials from a database, create new materials, and modify material properties.

These generic functions are described in this section. The inputs for temperature-dependent properties are explained in Defining Properties Using Temperature-Dependent Functions (p. 1590). The specific inputs for each material property are discussed in the remaining sections of this chapter.

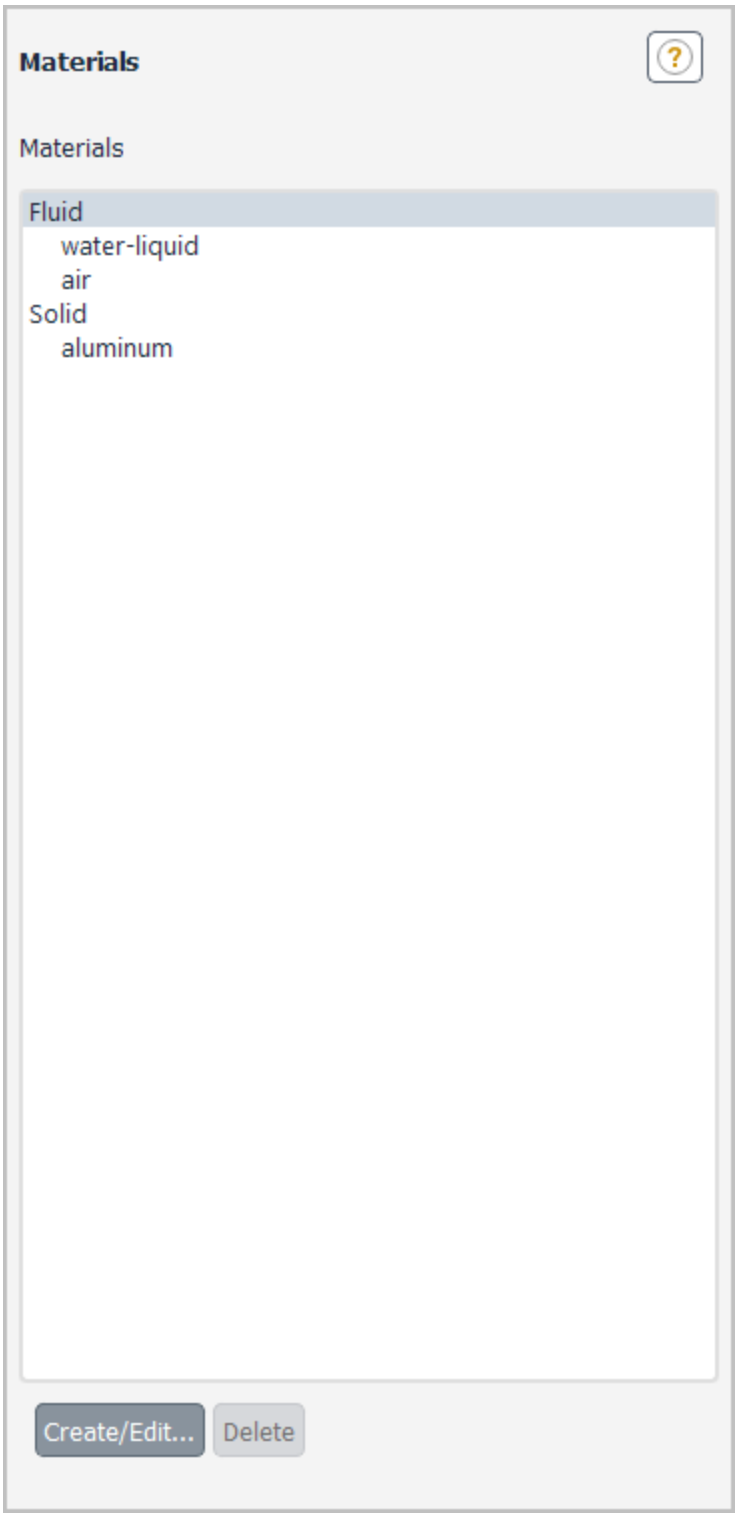
The Create/Edit Materials Dialog Box (p. 4833) can be accessed in one of two ways:

- Through the **Materials** task page.

Setup → **Materials**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 8.1: The Materials Task Page



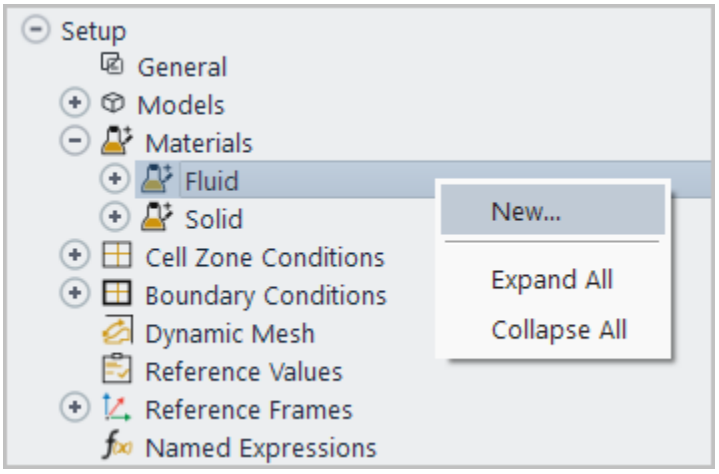
- Through the material types (**Fluid**, **Solid**, and so on) and defined in the case materials under **Materials** in the tree.

  For example, if you want to create a new fluid material you can access the **Create/Edit Materials** dialog box as follows:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setup → Materials → Fluid → New...

Figure 8.2: The Materials Branch in the Outline View



By default, your local materials list will include a single fluid material (air) and a single solid material (aluminum). If the fluid involved in your problem is air, you can use the default properties for air or modify the properties. If the fluid in your problem is water, you can either copy water from the Ansys Fluent database or create a new "water" material from scratch. If you copy water from the database, you can still make modifications to the properties of your local copy of water. See the following sections for detailed information on how to change material properties.

Mixture materials will not exist in your local list unless you have enabled species transport (see Modeling Species Transport and Finite-Rate Chemistry (p. 2353)). Similarly, inert, droplet, and combusting particle materials will not be available unless you have created a discrete phase injection of these particle types (see Modeling Discrete Phase (p. 2669)). When a mixture material is copied from the database, all of its constituent fluid materials (species) will automatically be copied over as well.

8.1.3.1. Modifying Properties of an Existing Material

Probably, the most common operation you will perform in the Create/Edit Materials Dialog Box (p. 4833) is the modification of properties for an existing material. The steps for this procedure are as follows:

1. In the Materials Task Page (p. 4831), select the material you want to modify and click the **Create/Edit...** button. (You can also right-click the material in the tree and select **Edit...** from the material submenu.)

2. In the Create/Edit Materials Dialog Box (p. 4833) select the type of material (**fluid**, **solid**, and so on) in the **Material Type** drop-down list.

3. Choose the material for which you want to modify properties, in the **Fluent Fluid Materials** drop-down list, **Fluent Solid Materials** list, or other similarly named list. The name of the list will be the same as the material type you selected in the previous step.

4. Make the required changes to the properties listed in the **Properties** section of the dialog box. You can use the scroll bar to the right of the **Properties** section to scroll through the listed items.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Click the **Change/Create** button to change the properties of the selected material to your new property settings.

To change the properties of an additional material, repeat the process described above. Click the **Change/Create** button after making changes to the properties for each material.

8.1.3.2. Renaming an Existing Material

Each material is identified by a name and a chemical formula (if one exists). You can change the name of a material, but not its chemical formula (unless you are creating a new material). The procedure for renaming a material is as follows:

1. In the Materials Task Page (p. 4831), select the material you want to rename and click the **Create/Edit...** button. (You can also right-click the material in the tree and select **Edit...** from the material submenu.)

2. In the Create/Edit Materials Dialog Box (p. 4833), choose the material for which you want to modify properties, in the **Fluent Fluid Materials** list, **Fluent Solid Materials** list, or other similarly named list. The name of the list will be the same as the material type you selected in the previous step.

3. Enter the new name in the **Name** field at the top of the Create/Edit Materials Dialog Box (p. 4833).

   Important:

   The maximum character length you can enter in the **Name** field is 29. If you enter a material name that is more than 29 characters long, Ansys Fluent will print an error message in the console window.

4. Click the **Change/Create** button.

   A Question Dialog Box (p. 907) will appear, asking you if the original material should be overwritten.

   If you are renaming the original material, click **Yes** to overwrite it. If you were creating a new material, click **No** to retain the original material.

To rename another material, repeat the process described above. Click the **Change/Create** button after renaming each material.

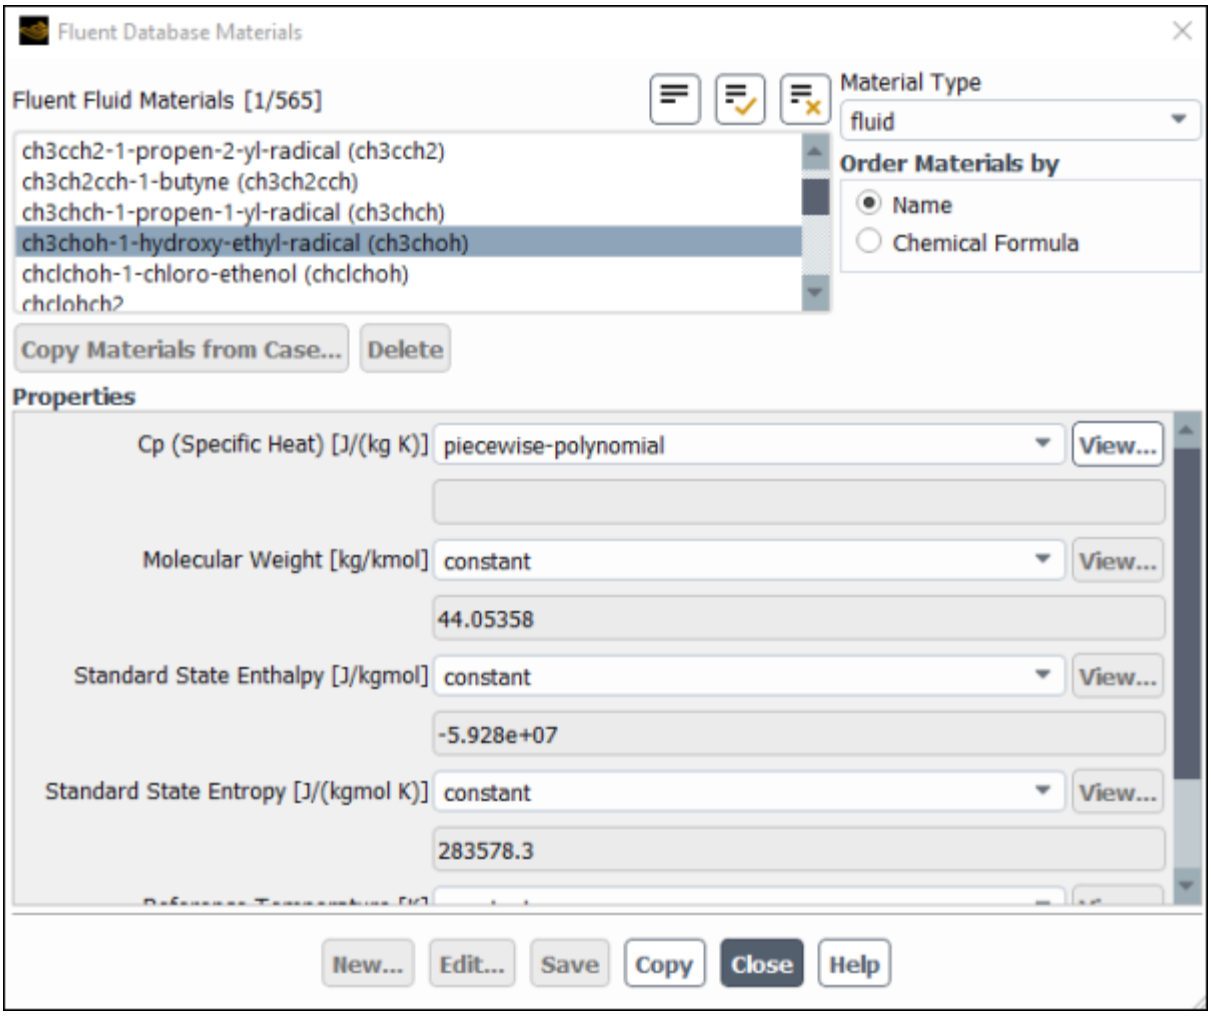
8.1.3.3. Copying Materials from the Ansys Fluent Database

The global (site-wide) materials database contains many commonly used fluid, solid, and mixture materials, with property data from several different sources [93] (p. 5660), [126] (p. 5662), [167] (p. 5664), [63] (p. 5658). To use one of these materials in your problem, copy it from the Ansys Fluent database to your local materials list. The procedure for copying a material is as follows:

1. Click the **Fluent Database...** button in the Create/Edit Materials Dialog Box (p. 4833) to open the Fluent Database Materials Dialog Box (p. 4845) (Figure 8.3: Fluent Database Materials Dialog Box (p. 1577)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 8.3: Fluent Database Materials Dialog Box



2. Select the type of material (**fluid**, **solid**, and so on) in the **Material Type** drop-down list.

3. In the **Fluent Fluid Materials** list, **Fluent Solid Materials** list, or other similarly named list, choose the materials you want to copy by clicking on them. The properties of the selected material will be displayed in the **Properties** area.

4. To check the material properties, use the scroll bar to the right of the **Properties** area to scroll through the listed items. For some properties, temperature-dependent functions are available in addition to the constant values. Select one of the function types in the drop-down list to the right of the property and the relevant parameters will be displayed. You cannot edit these values, but the dialog boxes in which they are displayed function in the same way as those used for setting temperature-dependent property functions (Defining Properties Using Temperature-Dependent Functions (p. 1590)).

   The inactive buttons in the Fluent Database Materials Dialog Box (p. 4845) are operations that are applicable only for a user-defined database. These operations will be available when you click the ***User-Defined Database...*** *button in the Create/Edit Materials Dialog Box (p. 4833).*

5. Click **Copy**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The materials and their properties will be downloaded from the database into your local list, and your copy of properties will now be displayed in the Materials Task Page (p. 4831) and in the tree under the appropriate material type.

6. Close the Fluent Database Materials Dialog Box (p. 4845).

After copying a material from the database, you can modify its properties or change its name, as described earlier in this section. The original material in the database will not be affected by any changes made to your local copy of the material.

8.1.3.4. Copying Materials from the Ansys GRANTA MDS Database

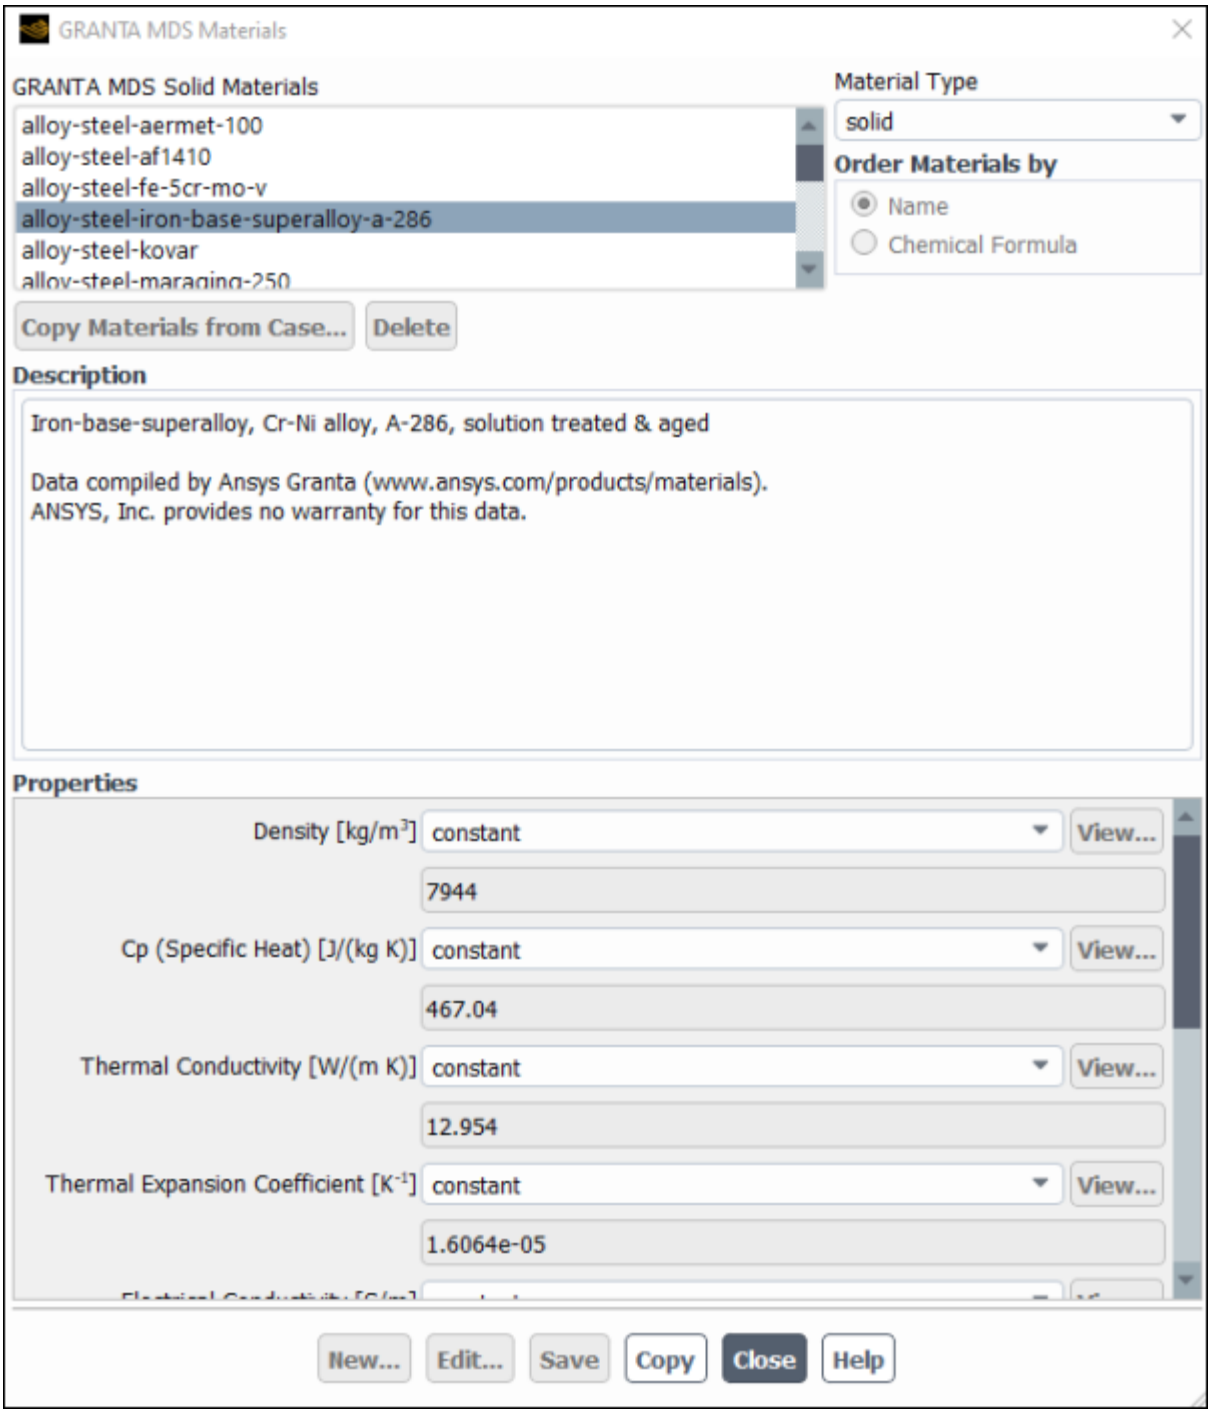
The procedure for copying a material is similar to that for the Ansys Fluent Database (Copying Materials from the Ansys Fluent Database (p. 1576)). Only the differences are highlighted here.

The global (site-wide) GRANTA MDS database contains many solid materials with property data from GRANTA. To use one of these materials, copy it from the Ansys GRANTA MDS database to your local materials list. Doing so requires a separate license.

1. Click the **GRANTA MDS Database...** button in the Create/Edit Materials Dialog Box (p. 4833) to open Figure 8.4: GRANTA MDS Materials Dialog Box (p. 1579).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 8.4: GRANTA MDS Materials Dialog Box



2. In the **GRANTA MDS Fluid Materials** list or **GRANTA MDS Solid Materials** list, choose the material you want to copy by clicking it (only one material can be selected at a time). A description of the selected material is displayed in the **Description** group box, and its properties are listed in the **Properties** group box.

   When no GRANTA license is available, only the description of the selected material will be displayed, but not its properties. The copy operation will abort with an information message.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The details of the remaining steps are covered in Copying Materials from the Ansys Fluent Database (p. 1576).

8.1.3.5. Creating a New Material

If the material you want to use is not available in the database, you can easily create a new material for the local list. This material will be available for use only for the current problem and will not be saved in the Ansys Fluent database. The procedure for creating a new material is as follows:

1. In the Materials Task Page (p. 4831), click the **Create/Edit...** button. (You can also right-click the corresponding material type in the tree (**Fluid**, **Solid**, and so on) and select **New...** from the material type submenu.)

2. Select the new material type (**fluid**, **solid**, and so on) in the **Material Type** drop-down list. It does not matter which material is selected in the **Fluent Fluid Materials**, **Fluent Solid Materials**, or other similarly named list.

3. Enter the new material name in the **Name** field.

   Important:

   The maximum character length you can enter in the **Name** field is 29. If you enter a material name that is more than 29 characters long, Ansys Fluent will print an error message in the console window.

4. Set the material's properties in the **Properties** area. If there are many properties listed, you may use the scroll bar to the right of the **Properties** area to scroll through the listed items.

5. Click the **Change/Create** button. A Question Dialog Box (p. 907) will appear, asking you if the original material should be overwritten.

   a. Click **No** to retain the original material and *add* your new material to the list. A dialog box will appear asking you to enter the chemical formula of your new material.

   b. Click **OK**, enter the formula if it is known. Else, leave the formula blank and click **OK**. Select the **Change/Create** button and answer the **Question**.

      The Materials Task Page (p. 4831) and the **Material** tree branch will be updated to show the new material name and chemical formula under the appropriate material type (**Fluid**, **Solid**, or others).

8.1.3.6. Saving Materials and Properties

All the materials and properties in your local list are saved in the case file when it is written. If you read this case file into a new solver session, all of your materials and properties will be available for use in the new session.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8.1.3.7. Deleting a Material

If there are materials list that you no longer need, you can delete them in one of the following ways:

- Using the Materials Task Page (p. 4831).

  In the Materials Task Page (p. 4831), select the material to be deleted and click the **Delete** button at the bottom of the Materials Task Page (p. 4831).

- Using the tree.

  Right-click the material in the tree and select **Delete** from the material submenu.

- Using the Create/Edit Materials Dialog Box (p. 4833).

  1. From the **Material Type** drop-down list, select the type of material (**fluid**, **solid**, and so on).
  2. Select the material to be deleted from the **Fluent Fluid Materials** drop-down list, **Fluent Solid Materials** list, or other similarly named list. The list's name will be the same as the material type you selected in the previous step.
  3. Click the **Delete** button.

Deleting materials from your local list will have no effect on the materials contained in the global database.

8.1.3.8. Changing the Order of the Materials List

By default, the materials in your local list and those in the database are listed alphabetically by name (for example, **air**, **atomic-oxygen (o)**, **carbon-dioxide (co2)**). If you prefer to list them alphabetically by chemical formula, select the **Chemical Formula** option under **Order Materials By**. The example materials listed, will now be in the order of: **air**, **co2 (carbon-dioxide)**, **o (atomic-oxygen)**. To change back to the alphabetical listing by name, choose the **Name** option under **Order Materials By**.

You may specify the ordering method separately for the Create/Edit Materials Dialog Box (p. 4833) and Fluent Database Materials Dialog Box (p. 4845). For example, you can order the database materials list by name. Each dialog box has its own **Order Materials By** options.

8.1.4. Using a User-Defined Materials Database

In addition to the Fluent Database Materials Dialog Box (p. 4845), you can also use or create a user-defined materials database using the User-Defined Database Materials Dialog Box (p. 4849). You can browse and do the following:

- select from existing user-defined databases
- copy materials from a user-defined database
- create a new database, create new materials
- add them to the user-defined database

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- delete materials from the database
- copy materials from a case to a user-defined database
- view the database

The following sections will address each of these functionalities in detail.

8.1.4.1. Opening a User-Defined Database

In Ansys Fluent, you can open databases of custom materials saved as `.scm` files and use them to define the materials in your problem setup. The material data must be prepared in a specific format as shown in the examples that follow.

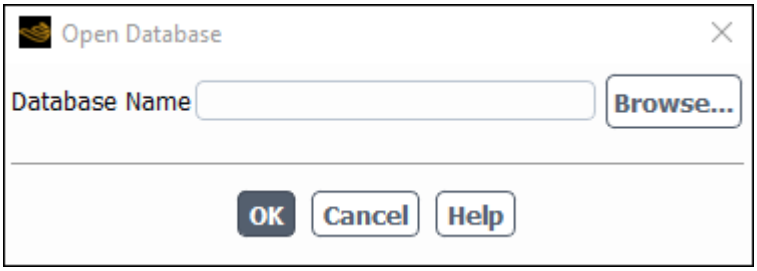
Examples:

The prescribed format for saving material properties information is shown here for air and aluminum. These files can be created in a text editor and saved with a `.scm` extension.

```
 ((air
 fluid
 (chemical-formula . #f)
 (density (constant . 1.225)
 (premixed-combustion 1.225 300))
 (specific-heat (constant . 1006.43))
 (thermal-conductivity (constant . 0.0242))
 (viscosity (constant . 1.7894e-05)
 (sutherland 1.7894e-05 273.11 110.56)
 (power-law 1.7894e-05 273.11 0.666))
 (molecular-weight (constant . 28.966))
 )
(aluminum
 solid
 (chemical-formula . al)
 (density (constant . 2719))
 (specific-heat (constant . 871))
 (thermal-conductivity (constant . 202.4))
 (formation-entropy (constant . 164448.08))
 ))
```

To select a user-defined database, click the **User-Defined Database...** button in the Create/Edit Materials Dialog Box (p. 4833). This will open the Open Database Dialog Box (p. 4849).

Figure 8.5: Open Database Dialog Box



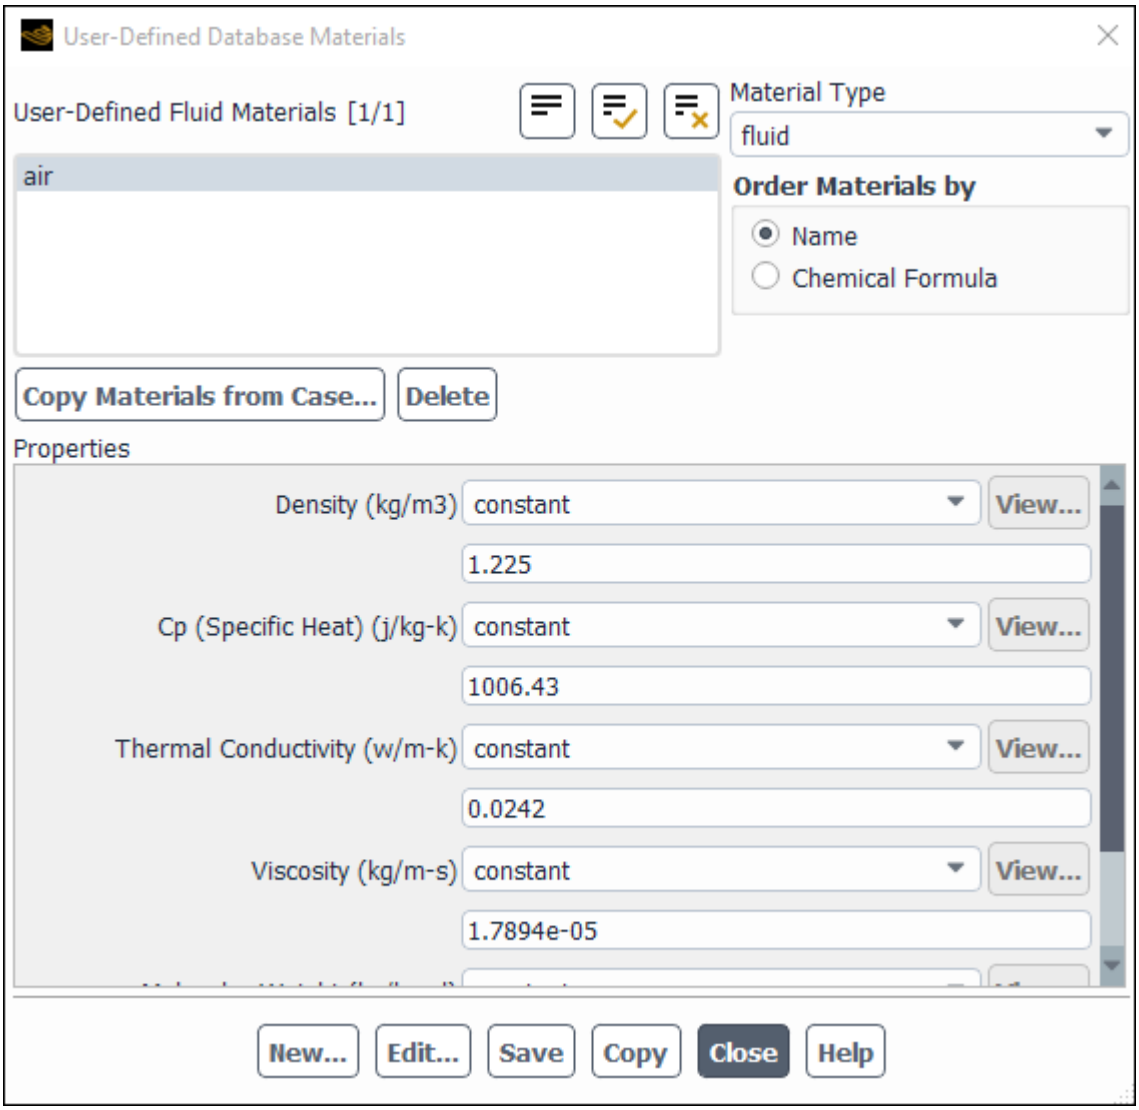
Click the **Browse...** button, select the database in The Select File Dialog Box (p. 907) that opens and click **OK**. Click **OK** in the Open Database Dialog Box (p. 4849) to open the User-Defined Database Materials Dialog Box (p. 4849).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8.1.4.2. Viewing Materials in a User-Defined Database

When an existing user-defined database is opened, the materials present in the database are listed in the User-Defined Database Materials Dialog Box (p. 4849). You can select the material type in the **Material Type** drop-down list and the corresponding materials will appear in the **User-Defined Fluid Materials**, **User-Defined Solid Materials** or other similarly named list. The name of the list will be the same as the material type you selected.

Figure 8.6: User-Defined Database Materials Dialog Box



The properties of the selected material will appear in the **Properties** section of the dialog box. This dialog box is similar to the Fluent Database Materials Dialog Box (p. 4845) in function and operation.

8.1.4.3. Copying Materials from a User-Defined Database

The procedure for copying a material from a custom database is as follows:

1. In the Create/Edit Materials Dialog Box (p. 4833), click the **User-Defined Database...** button and open the database from which you want to copy the material.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. In the User-Defined Database Materials Dialog Box (p. 4849) of the selected database, select the type of material (**fluid**, **solid**, and so on) in the **Material Type** drop-down list.

3. In the **User-Defined Fluid Materials** list, **User-Defined Solid Materials** list, or other similarly named list (the list's name will be the same as the material type you selected in the previous step), choose the materials you want to copy by clicking on them. The properties are displayed in the **Properties** area.

4. If you want to check the material properties, use the scroll bar to the right of the **Properties** area to scroll through the listed items.

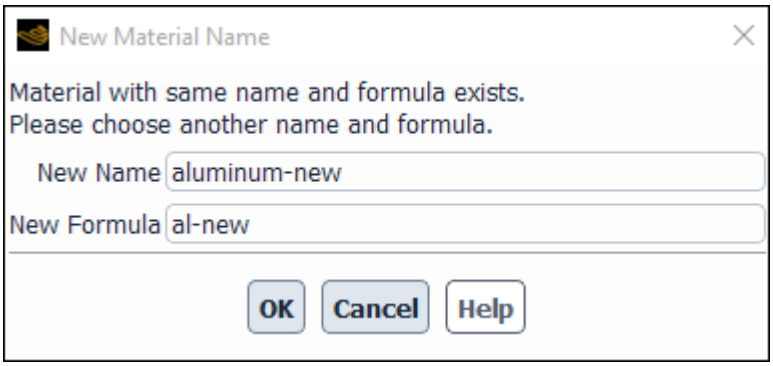
5. Click the **Copy** button.

   The selected materials and their properties will be copied from the database into your local list, and your copy of the properties will now be displayed in the Materials Task Page (p. 4831) and under the **Materials** tree branch.

   To copy all the materials from the database in one step, click the button (*) next to **User-Defined Materials** title and click **Copy**.*

   If a material with the same name is already defined in the case, Ansys Fluent will prompt you to enter a new name and formula in the New Material Name Dialog Box (p. 4854). Enter a new name and formula in the respective fields and click **OK** to make a local copy of the material.

   Figure 8.7: New Material Name Dialog Box



6. Close the User-Defined Database Materials Dialog Box (p. 4849).

After copying a material from the database, you may modify its properties or change its name, as described earlier in Using the **Create/Edit Materials** Dialog Box (p. 1573). The material in the database will not be affected by any changes you make to your local copy of the material.

8.1.4.4. Copying Materials from the Case to a User-Defined Database

The procedure for copying a material to a custom database is as follows:

1. In the Create/Edit Materials Dialog Box (p. 4833), click **User-Defined Database...**.

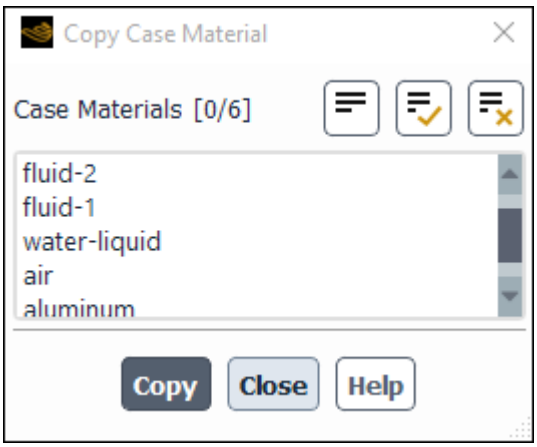
2. In the Open Database Dialog Box (p. 4849), select the database to which you want to copy the material. If you want to create a new database, enter the name of the new database in the

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Database Name field and click **OK**. A Question Dialog Box (p. 907) will ask you to confirm if you want to create a new file. Click **Yes** to confirm.

3. In the User-Defined Database Materials Dialog Box (p. 4849), click **Copy Materials From Case....** This will open the Copy Case Material Dialog Box (p. 4851).

Figure 8.8: Copy Case Material Dialog Box



a. In the Copy Case Material Dialog Box (p. 4851), select the materials that you want to copy.

*To select all the materials, click the shaded icon to the right of the **Case Materials** title. Clicking on the unshaded icon will deselect the selections in the list.*

b. Click **Copy** and close the dialog box.

> **Note:**
>
> Do not copy materials one by one. This will result in previously copied materials getting overwritten by the new ones. Instead, select all the materials to be copied and click **Copy**.

8.1.4.5. Modifying Properties of an Existing Material

You can modify the properties of an existing material and use the modified material in the problem setup and save the modified material to the materials database.

1. In the Create/Edit Materials Dialog Box (p. 4833), click the **User-Defined Database...** button and open the database that you want to use.

   a. In the User-Defined Database Materials Dialog Box (p. 4849) of the selected database, select the type of material (**fluid**, **solid**, and so on) in the **Material Type** drop-down list.

   b. In the **User-Defined Fluid Materials** list, **User-Defined Solid Materials** list, or other similarly named list (the name of the list will be the same as the material type you selected in the previous step), select the material to be modified.

   c. Click **Edit...** to open the Material Properties Dialog Box (p. 4852).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

i. In the **Materials Properties** list, select the property to be modified and click **Edit...** to open the Edit Property Methods Dialog Box (p. 4853).

ii. Select the method to be modified in the **Material Properties** list of the Edit Property Methods Dialog Box (p. 4853) and click **Edit...** under **Edit Properties**, in order to modify the properties.

iii. Make the changes in the corresponding method dialog box and click **OK**.

iv. Click **Apply** in the Material Properties Dialog Box (p. 4852).

d. To use the modified material in the problem setup, click **Copy** in the User-Defined Database Materials Dialog Box (p. 4849).

e. To save the modified material to the database, click **Save** and close the dialog box.

8.1.4.6. Creating a New Materials Database and Materials

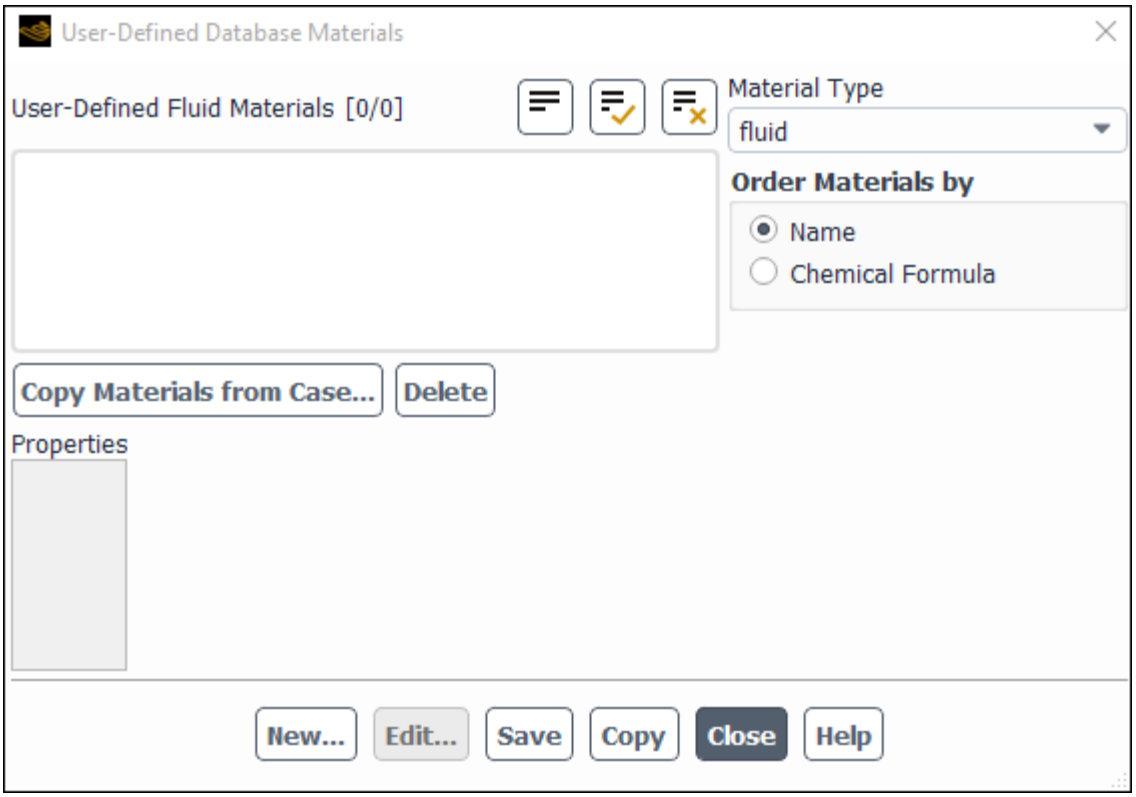
Using the Create/Edit Materials Dialog Box (p. 4833), you can create a new materials database, copy materials to this database, and also create new materials from scratch. The procedure for creating a new database and add new materials to the database is as follows:

1. In the Materials Task Page (p. 4831), click **User-Defined Database...**.
2. In the Open Database Dialog Box (p. 4849), enter the name of the database that you are creating and click **OK**.
3. A dialog box will appear asking you confirm the creation of a new file. Click **Yes** to confirm.

   This will open a blank User-Defined Database Materials Dialog Box (p. 4849) (Figure 8.9: User-Defined Database Materials Dialog Box: Blank (p. 1587)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

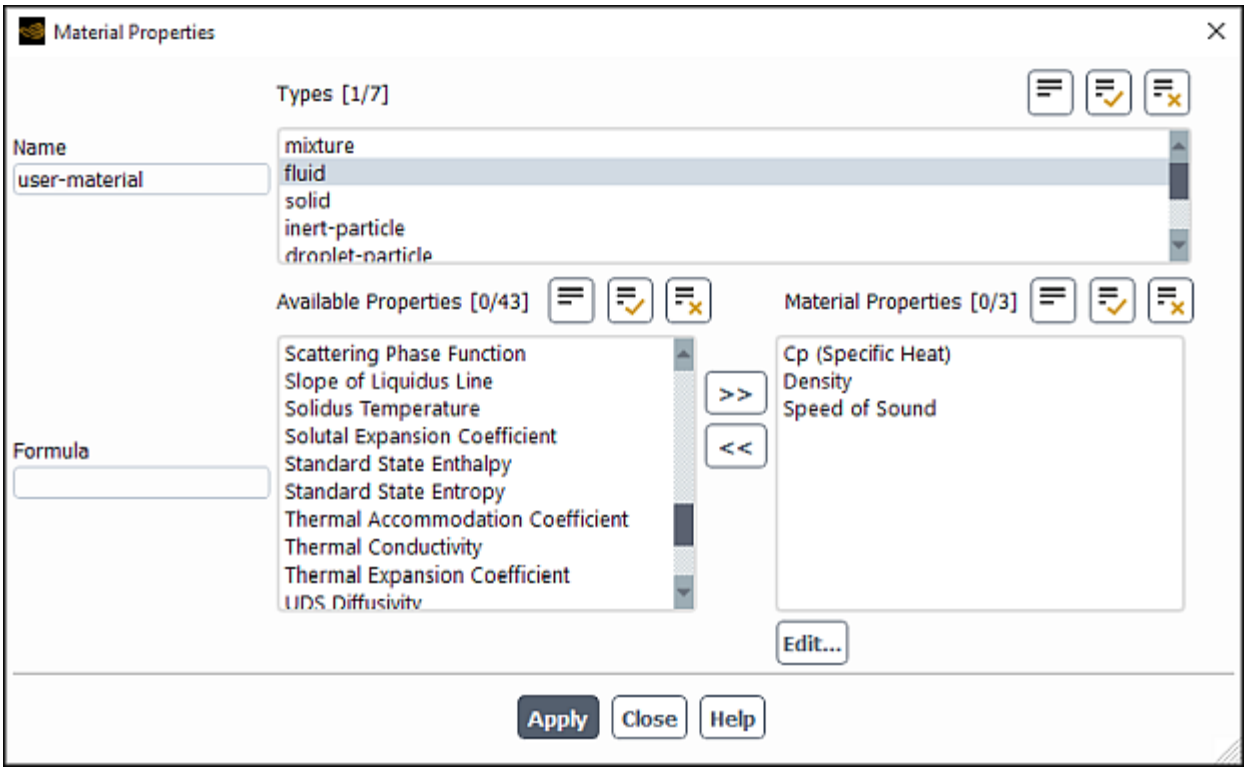
Figure 8.9: User-Defined Database Materials Dialog Box: Blank



4. Click **New...** in the User-Defined Database Materials Dialog Box (p. 4849). This will open a blank **Material Properties** dialog box.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 8.10: Material Properties Dialog Box: Blank



a. In the Material Properties Dialog Box (p. 4852), under **Types**, select the material type. You can select from **fluid**, **solid**, **inert-particle**, **droplet-particle**, **combusting-particle**, and **mixture** materials.

b. Enter the name and formula (if required) of the material that you are creating in the **Name** and **Formula** fields.

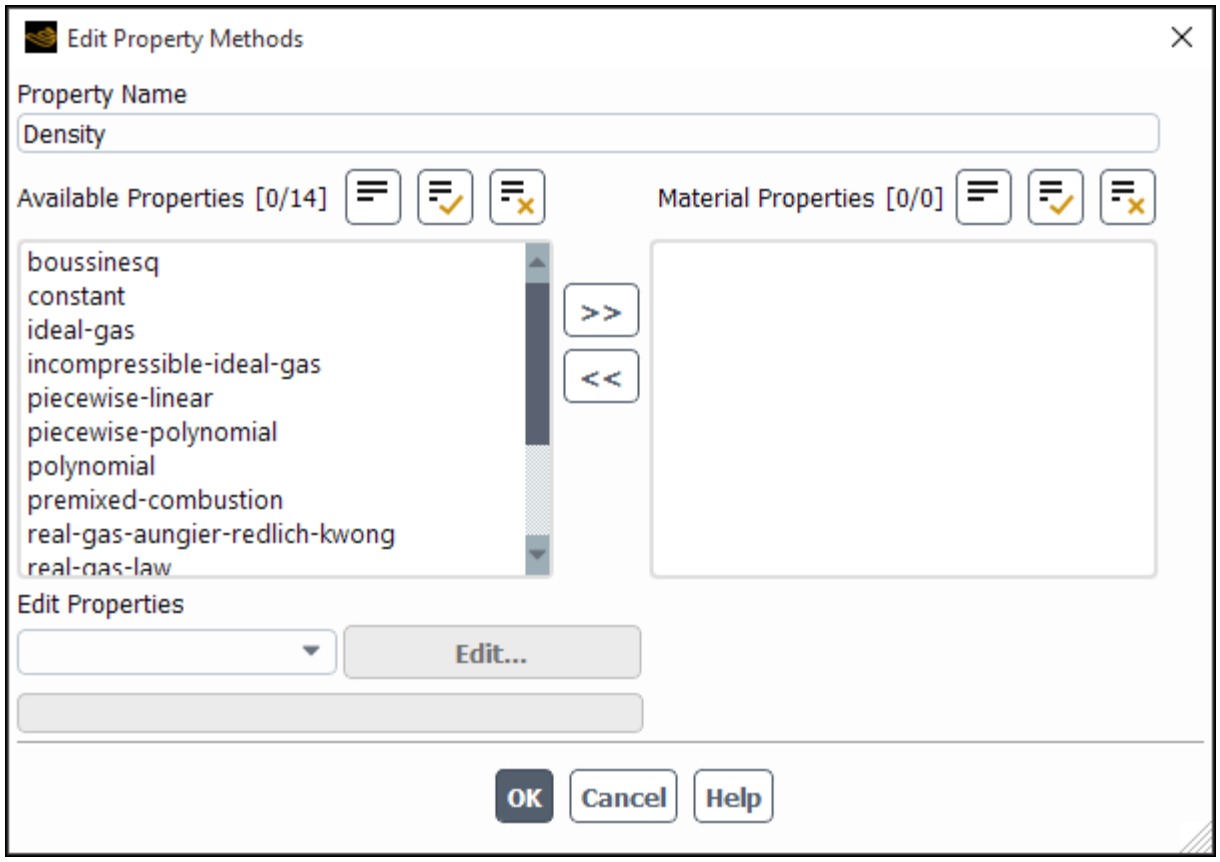
c. Depending on the type of material selected in the **Types** list, properties applicable to that material type will appear in the **Available Properties** list. Select the properties that are applicable for the material that you are defining by clicking on them.

d. Click the ≫ button to move these properties to the **Material Properties** list on the right and click **Apply**. You can use the ≪ button to move the property from the **Material Properties** list to the **Available Properties** list.

5. To edit the parameters that define a property, select the property in the **Material Properties** list and click **Edit...**. This opens the Edit Property Methods Dialog Box (p. 4853).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 8.11: Edit Property Methods Dialog Box



a. The methods that can be used to define the selected property are listed in the **Available Properties** list. You can select one or more methods and specify them for the material that you are defining, by selecting and moving them to the **Material Properties** list.

b. To modify each of these methods, you can select the method in the **Edit Properties** drop-down list and click **Edit...**. This will open the corresponding property dialog box, where you can modify the parameters used by the property method. Refer to Defining Properties Using Temperature-Dependent Functions (p. 1590) to Real Gas Models (p. 1655) for details of these properties, methods used to define the properties and the parameters for each method.

c. Click **OK** in the Edit Property Methods Dialog Box (p. 4853).

6. Click **Apply** in the Material Properties Dialog Box (p. 4852).

7. Click **Save** in the User-Defined Database Materials Dialog Box (p. 4849) to save the changes to the new materials database.

Similarly, you can also append new materials and click save to append these materials to the existing database.

8.1.4.7. Deleting Materials from a Database

To delete a material from a database, click the **User-Defined Database** button in the Open Database Dialog Box (p. 4849). Select the database and click **OK** in the Open Database Dialog Box (p. 4849). Select

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the **Material Type** and the materials that you want to delete in the **User-Defined Materials** list and click **Delete**. Click **Save** to save the database.

8.2. Defining Properties Using Temperature-Dependent Functions

Material properties can be defined as functions of temperature. For most properties, you can define a polynomial, piecewise-linear, or piecewise-polynomial function of temperature. For specific heat (Cp), you can also use a nasa-9-piecewise-polynomial function of temperature in extremely high-temperature applications. The definitions of these functions are as follows:

- polynomial:

$$\phi(T) = A_1 + A_2 T + A_3 T^2 + \ldots \tag{8.1}$$

- piecewise-linear:

$$\phi(T) = \phi_n + \frac{\phi_{n+1} - \phi_n}{T_{n+1} - T_n}(T - T_n) \tag{8.2}$$

  where $1 \le n \le N$ and N is the number of segments

- piecewise-polynomial:

$$\begin{aligned} &\text{for } T_{min,1} \le T < T_{max,1}: \phi(T) = A_1 + A_2 T + A_3 T^2 + \ldots \\ &\text{for } T_{min,2} \le T < T_{max,2}: \phi(T) = B_1 + B_2 T + B_3 T^2 + \ldots \end{aligned} \tag{8.3}$$

- nasa-9-piecewise-polynomial:

$$\begin{aligned} &\text{for } \quad T_{min,1} \le T < T_{max,1}: Cp(T) = A_1 T^{-2} + A_2 T^{-1} + A_3 + A_4 T + A_5 T^2 + A_6 T^3 + A_7 T^4 \\ &\text{for } \quad T_{min,2} \le T < T_{max,2}: Cp(T) = B_1 T^{-2} + B_2 T^{-1} + B_3 + B_4 T + B_5 T^2 + B_6 T^3 + B_7 T^4 \end{aligned} \tag{8.4}$$

In the equations above, ϕ is the property.

Important:

If you define a polynomial or piecewise-polynomial function of temperature, the temperature in the function is always in units of Kelvin or Rankine. If you use Celsius or Kelvin as the temperature unit, then polynomial coefficient values must be entered in terms of Kelvin. If you use Fahrenheit or Rankine as the temperature unit, enter the values in terms of Rankine.

Some properties have additional functions available and for some only a subset of these three functions can be used. See the section on the property in question to determine which temperature-dependent functions you can use.

For additional information, see the following sections:

8.2.1. Inputs for Polynomial Functions
8.2.2. Inputs for Piecewise-Linear Functions
8.2.3. Inputs for Piecewise-Polynomial Functions
8.2.4. Inputs for NASA-9-Piecewise-Polynomial Functions
8.2.5. Checking and Modifying Existing Profiles

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8.2.1. Inputs for Polynomial Functions

To define a polynomial function of temperature for a material property, do the following:

1. In the Create/Edit Materials Dialog Box (p. 4833), choose **polynomial** in the drop-down list to the right of the property name (for example, **Density**). The Polynomial Profile Dialog Box (p. 4854) (Figure 8.12: The Polynomial Profile Dialog Box (p. 1591)) will open automatically.

   Figure 8.12: The Polynomial Profile Dialog Box

   Since this is a modal dialog box, the solver will not allow you to do anything else until you perform the following steps.

   a. Specify the number of **Coefficients** up to 8 coefficients are available. The number of coefficients defines the order of the polynomial. The default of 1 defines a polynomial of order 0. The property will be constant and equal to the single coefficient A_1. An input of 2 defines a polynomial of order 1 and the property will vary linearly with temperature and so on.

   b. Define the coefficients. Coefficients **1**, **2**, **3**,... correspond to A_1, A_2, A_3,... in Equation 8.1 (p. 1590). The dialog box in Figure 8.12: The Polynomial Profile Dialog Box (p. 1591) shows the inputs for the following function:

$$\rho(T) = 1000 - 0.02T \tag{8.5}$$

c. To visualize your profile, ensure the correct **Primary Independent Variable** is selected from the drop-down list, and enter a value for the **Min** and **Max**.

Important:

To ensure the robustness of simulations when using polynomials to specify material property, set the solution limits so that the values returned by the polynomial expression are physically valid. For example, when the density of a material is specified as a function of temperature using a polynomial expression, set the proper limits on the temperature range so that the density is always non-negative. For more information on setting solution limits see Setting Solution Limits (p. 3607).

Also, note the restriction on the units for temperature, as described in the previous section.

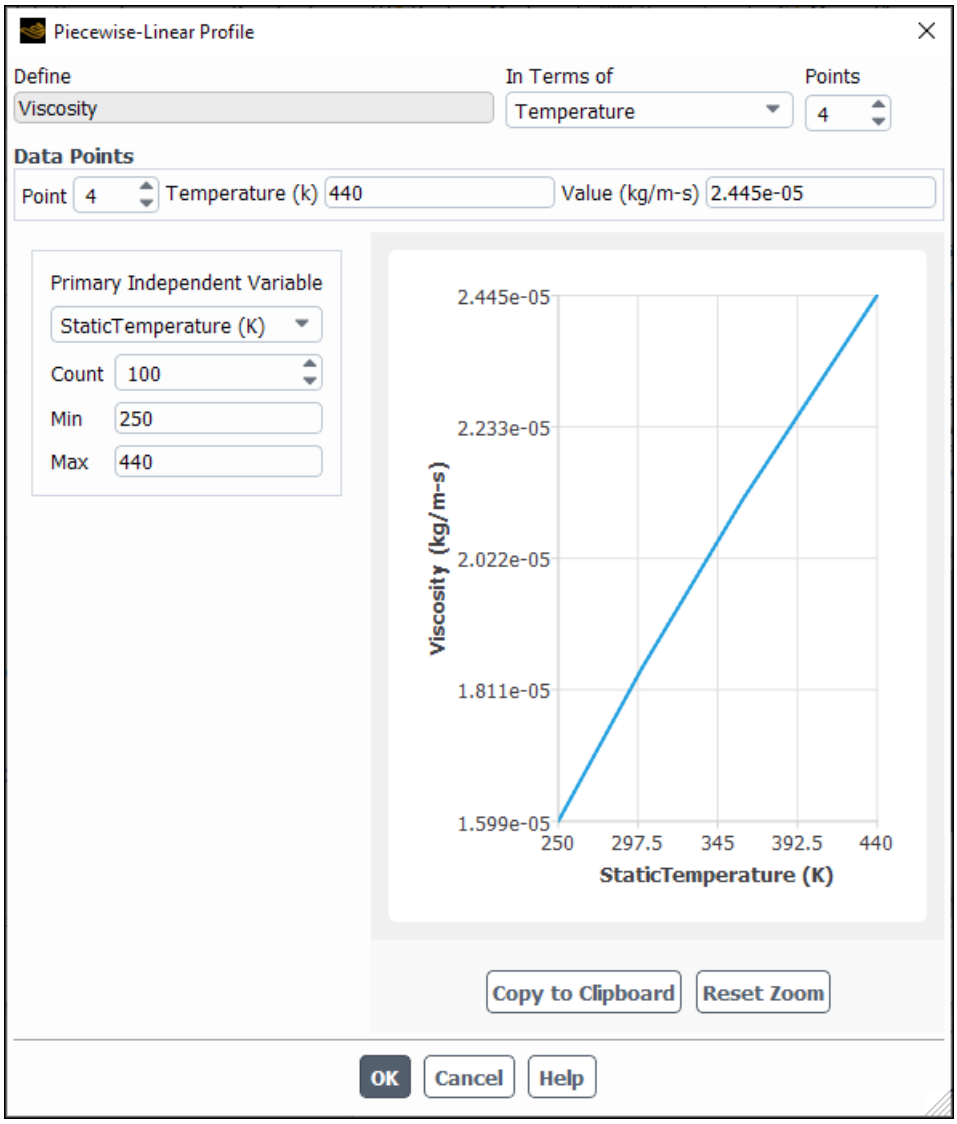
8.2.2. Inputs for Piecewise-Linear Functions

To define a piecewise-linear function of temperature for a material property, do the following:

1. In the Create/Edit Materials Dialog Box (p. 4833), choose **piecewise-linear** in the drop-down list to the right of the property name (for example, **Viscosity**). The Piecewise-Linear Profile Dialog Box (p. 4855) (Figure 8.13: The Piecewise-Linear Profile Dialog Box (p. 1593)) will open automatically.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 8.13: The Piecewise-Linear Profile Dialog Box



Since this is a modal dialog box, the solver will not allow you to do anything else until you perform the following steps.

a. Set the number of **Points** defining the piecewise distribution.

b. Under **Data Points**, enter the data pairs for each point. First enter the independent and dependent variable values for **Point** 1, then increase the **Point** number and enter the appropriate values for each additional pair of variables. The pairs of points must be supplied in the order of increasing value of temperature. The solver will *not* sort them for you. A maximum of 50 piecewise points can be defined for each property. The dialog box in Figure 8.13: The Piecewise-

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

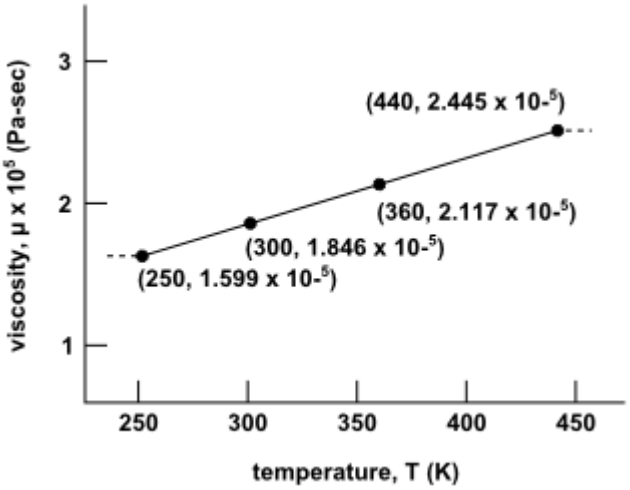
Linear Profile Dialog Box (p. 1593) shows the final inputs and a plot of the profile that is depicted in Figure 8.14: Piecewise-Linear Definition of Viscosity as a Function of Temperature (p. 1594).

Important:

If the temperature exceeds the maximum **Temperature** (T_{max}) you have specified for the profile, Ansys Fluent will use the **Value** corresponding to T_{max}. If the temperature falls below the minimum **Temperature** (T_{min}) specified for your profile, Ansys Fluent will use the **Value** corresponding to T_{min}.

c. To visualize your profile, ensure the correct **Primary Independent Variable** is selected from the drop-down list, and enter a value for the **Min** and **Max**.

Figure 8.14: Piecewise-Linear Definition of Viscosity as a Function of Temperature



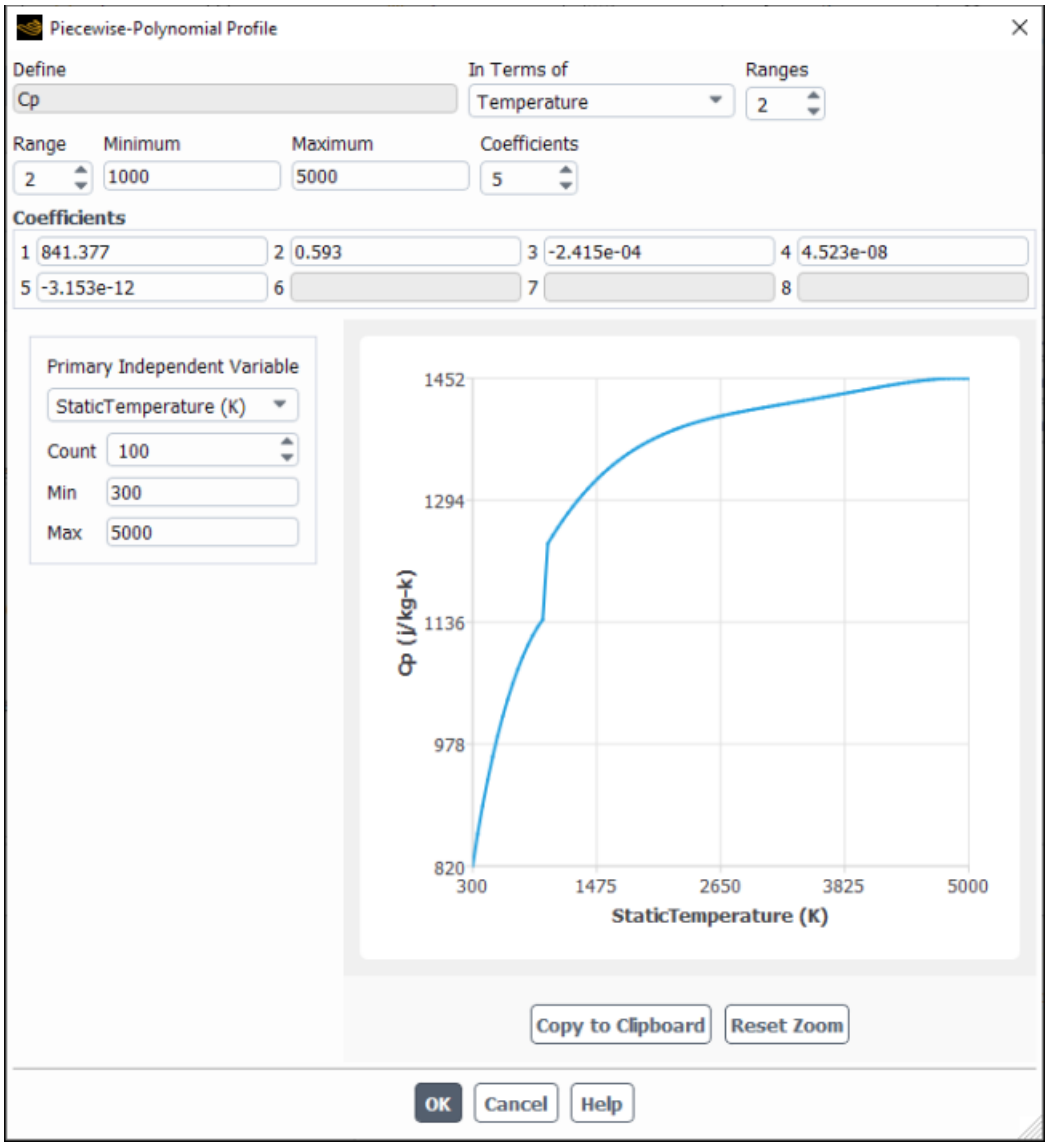
8.2.3. Inputs for Piecewise-Polynomial Functions

To define a piecewise-polynomial function of temperature for a material property, follow these steps:

1. In the Create/Edit Materials Dialog Box (p. 4833), choose **piecewise-polynomial** in the drop-down list to the right of the property name (for example, **Cp**). The Piecewise-Polynomial Profile Dialog Box (p. 4857) (Figure 8.15: The Piecewise-Polynomial Profile Dialog Box (p. 1595)) will open automatically. Since this is a modal dialog box, first perform the following steps.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 8.15: The Piecewise-Polynomial Profile Dialog Box



2. Specify the number of **Ranges**. For the example of Equation 8.6 (p. 1595), two ranges of temperatures are defined:

$$c_p(T) = \begin{cases} 429.929 + 1.784T - 1.966\times10^{-3}T^2 \\ \quad +1.297\times10^{-6}T^3 - 4.000\times10^{-10}T^4 & for\ 300 \le T < 1000 \\ 841.377 + 0.593T - 2.415\times10^{-4}T^2 \\ \quad +4.523\times10^{-8}T^3 - 3.153\times10^{-12}T^4 & for\ 1000 \le T < 5000 \end{cases} \tag{8.6}$$

   You may define up to three ranges. The ranges must be supplied in the order of increasing value of temperature. The solver will *not* sort them for you.

3. For the first range (**Range** = 1), specify the **Minimum** and **Maximum** temperatures, and the number of **Coefficients**. (Up to eight coefficients are available.) The number of coefficients defines the order of the polynomial. The default of 1 defines a polynomial of order 0. The property will

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

be constant and equal to the single coefficient A_1. An input of 2 defines a polynomial of order 1. The property will vary linearly with temperature and so on.

4. Define the coefficients. **Coefficients 1**, **2**, **3**,... correspond to A_1, A_2, A_3,... in Equation 8.3 (p. 1590). The dialog box in Figure 8.15: The Piecewise-Polynomial Profile Dialog Box (p. 1595) shows the inputs for the first range of Equation 8.6 (p. 1595).

5. Increase the value of **Range** and enter the **Minimum** and **Maximum** temperatures, number of **Coefficients**, and the **Coefficients** (B_1, B_2, B_3,...) for the next range. Repeat if there is a third range.

6. To visualize your profile, ensure the correct **Primary Independent Variable** is selected from the drop-down list, and enter a value for the **Min** and **Max**.

8.2.4. Inputs for NASA-9-Piecewise-Polynomial Functions

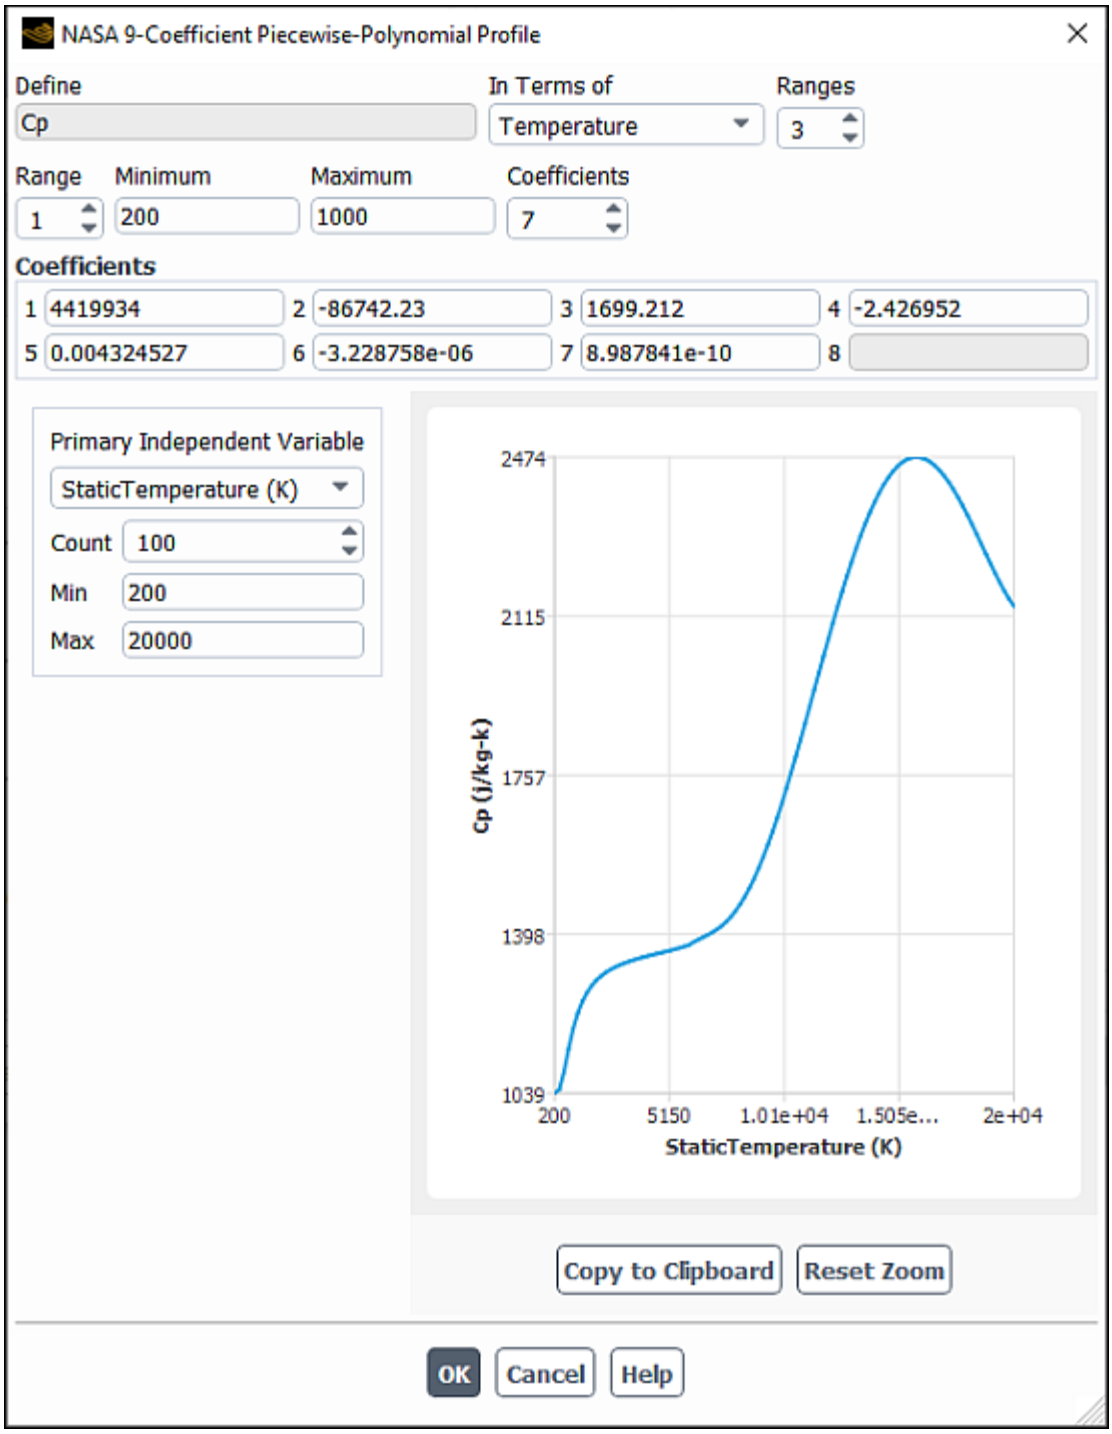
This function is available for specific heat only and is useful for hypersonic flows, and can be used with the two-temperature model, where piecewise-polynomial temperature profiles are not valid.

The procedure for defining a nasa-9-piecewise-polynomial function of temperature is similar to that for the piecewise-polynomial function:

1. In the Create/Edit Materials Dialog Box (p. 4833), choose **nasa-9-piecewise-polynomial** from the **Cp (Specific Heat)** drop-down list (**Properties** group box). The **NASA-9-Coefficient Piecewise-Polynomial Profile** dialog box opens automatically with **Cp** and **Temperature** displayed in the **Define** and **In Terms of** fields, respectively (see Figure 8.16: The NASA-9-Coefficient Piecewise-Polynomial Profile Dialog Box (p. 1597)). Note that because this is a modal dialog box, you must tend to it immediately.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 8.16: The NASA-9-Coefficient Piecewise-Polynomial Profile Dialog Box



2. Specify the number of **Ranges**.

   You may define up to eight ranges. The ranges must be supplied in the order of increasing value of temperature. The solver will *not* sort them for you.

3. For the first range (**Range** = 1) specify:

   - The **Minimum** and **Maximum** temperatures

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The number of **Coefficients**

  Up to eight coefficients are available

- **Coefficients 1**, **2**, **3**, and so on.

  Coefficients **1**, **2**, **3**,... correspond to A_1, A_2, A_3,..., respectively, in Equation 8.4 (p. 1590).

To visualize your profile, enter a value for the **Min** and **Max**. Note that **Static Temperature** is automatically selected from the **Primary Independent Variable** drop-down list. You can increase or decrease the value of **Count** to control the smoothness of the profile curve. *You can click and drag in the plot to change the zoom level.*

4. Increase the value of **Range** and enter the **Minimum** and **Maximum** temperatures, number of **Coefficients**, and their values (B_1, B_2, B_3, and so on) for the next range.

5. Repeat the previous step for every range if there are more than two ranges.

8.2.5. Checking and Modifying Existing Profiles

If you want to check or change the coefficients, data pairs, or ranges for a previously-defined profile, click the **Edit...** button to the right of the property name. The appropriate dialog box will open, and you can check or modify the inputs as desired.

Important:

In the Fluent Database Materials Dialog Box (p. 4845), you cannot edit the profiles, but you can examine them by clicking on the **View...** button (instead of the **Edit...** button.)

8.3. Density

Ansys Fluent provides several options for definition of the fluid density:

- constant density
- temperature and/or composition-dependent density
- pressure-dependent density

Each of these input options and the governing physical models are explained in the following sections. In all cases, you will define the **Density** in the Create/Edit Materials Dialog Box (p. 4833).

Setup → Materials

Note:

For transient, variable-density flows that use the pressure-based solver, you may reach convergence faster if you specify that the model equations are solved in an optimal order. For details, see Equation Order (p. 3586).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For additional information, see the following sections:

8.3.1. Defining Density for Various Flow Regimes
8.3.2. Input of Constant Density
8.3.3. Inputs for the Boussinesq Approximation
8.3.4. Compressible Liquid Density Method
8.3.5. Density as a Profile Function of Temperature
8.3.6. Incompressible Ideal Gas Law
8.3.7. Ideal Gas Law for Compressible Flows
8.3.8. Composition-Dependent Density for Multicomponent Mixtures

8.3.1. Defining Density for Various Flow Regimes

The selection of density in Ansys Fluent is very important. Set the density relationship based on your flow regime.

- For compressible flows, the ideal gas law is the appropriate density relationship.
- For incompressible flows, you may choose one of the following methods:
  - Constant density, if you do not want density to be a function of temperature.
  - The incompressible ideal gas law, when pressure variations are small enough that the flow is fully incompressible but you want to use the ideal gas law to express the relationship between density and temperature (for example, for a natural convection problem).
  - Density as a polynomial, piecewise-linear, or piecewise-polynomial function of temperature, when the density is a function of temperature only, as in a natural convection problem.
  - The Boussinesq model, for natural convection problems involving small changes in temperature.
  - The compressible liquid density method allows you to model compressible liquids under high pressures.

8.3.1.1. Mixing Density Relationships in Multiple-Zone Models

If your model has multiple fluid zones that use different materials, you should be aware of the following:

- For calculations with the pressure-based solver that do not use one of the general multiphase models (Solution Strategies for Multiphase Modeling (p. 3177)), the compressible ideal gas law cannot be mixed with any other density methods. This means that if the compressible ideal gas law is used for one material, it must be used for all materials.

  This restriction does not apply to the density-based solvers.

- There is only one specified operating pressure and one specified operating temperature. This means that if you are using the ideal gas law for more than one material, they will share the same operating pressure. If you are using the Boussinesq model for more than one material, they will share the same operating temperature.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8.3.2. Input of Constant Density

If you want to define the density of the fluid as a constant, select **constant** in the **Density** drop-down list under **Properties** in the Create/Edit Materials Dialog Box (p. 4833). Enter the value of density for the material.

For the default fluid (air), the density is 1.225 kg/m^3.

8.3.3. Inputs for the Boussinesq Approximation

To enable the Boussinesq approximation for density, choose **boussinesq** from the **Density** drop-down list in the Create/Edit Materials Dialog Box (p. 4833) and specify a constant value for **Density**. You will also need to set the **Thermal Expansion Coefficient**, as well as relevant operating conditions, as described in The Boussinesq Model (p. 1366).

8.3.4. Compressible Liquid Density Method

The compressible liquid treatment enables you to model liquid compressibility under high pressure applications. Fluent models compressible liquids using the Tait equation of state, which establishes a nonlinear relationship between density and pressure under isothermal conditions.

The compressible liquid treatment also helps in reducing unphysical pressure spikes that appear in moving and dynamic mesh applications, especially during solid-fluid interactions.

The Tait equation can be represented in terms of pressure and density using the following relationship:

$$p = a + b\rho^n \tag{8.7}$$

where, a and b are coefficients that can be determined by assuming that the bulk modulus is a linear function of pressure. The values of coefficients a and b are based on the reference state values of pressure, density, and bulk modulus.

The simplified form of the Tait equation can be written as:

$$\left(\frac{\rho}{\rho_0}\right)^n = \frac{K}{K_0} \tag{8.8}$$

where,

$$K = K_0 + n\Delta p \tag{8.9}$$

and

$$\Delta p = p - p_0 \tag{8.10}$$

where,

p_0 = Reference liquid pressure (Absolute)

ρ_0 = Reference liquid density (Density at reference pressure, p_0)

K_0 = Reference bulk modulus (Bulk modulus at reference pressure, p_0)

n = Density exponent

p = Liquid pressure (Absolute)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ρ = Liquid density at pressure, p

K = Bulk modulus at pressure, p

The density ratio is limited to the range:

$$\rho_{r,min} < \frac{\rho}{\rho_0} < \rho_{r,max} \tag{8.11}$$

where,

$\rho_{r,min}$= Minimum density ratio limit, when $p<p_0$

$\rho_{r,max}$= Maximum density ratio limit, when $p>p_0$

The speed of sound, c, is calculated as:

$$c=\sqrt{\frac{K}{\rho}} \tag{8.12}$$

Note:

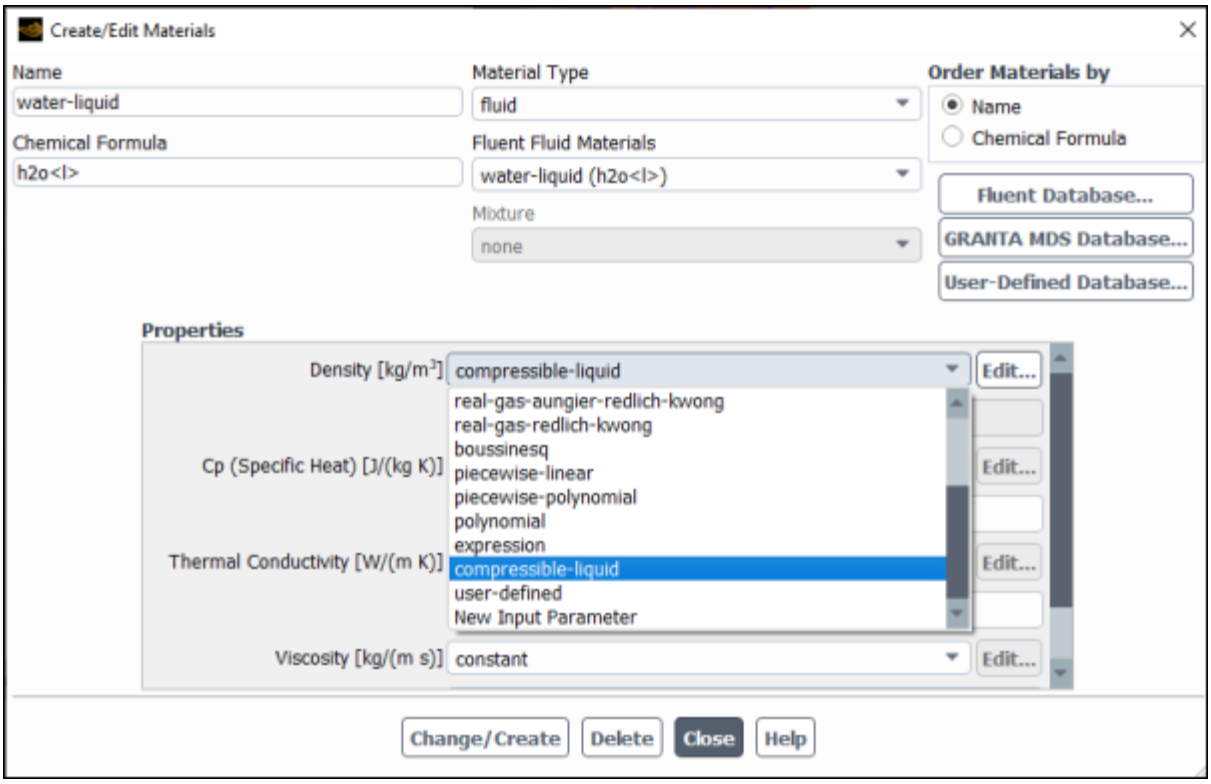
You can postprocess the speed of sound for compressible liquid materials. For multiphase models, sound-speed postprocessing is available at mixture and/or phase level, depending on the model selected. Sound-speed postprocessing is also enabled if you describe the speed of sound for a user-defined density.

8.3.4.1. Compressible Liquid Inputs

Select the `compressible-liquid` under **Density** in the **Create/Edit Materials** panel as seen in Figure 8.17: Compressible Liquid Materials Setting (p. 1602).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 8.17: Compressible Liquid Materials Setting

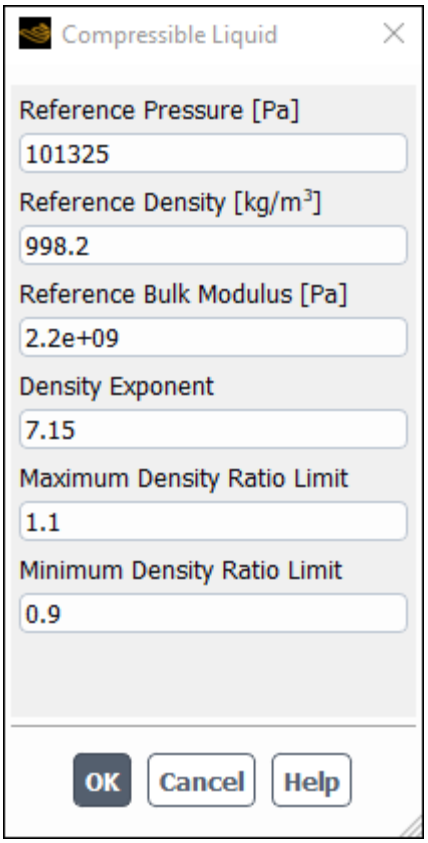


In the **Compressible Liquid** dialog box you need to specify values for the following settings:

- Reference Pressure
- Reference Density
- Reference Bulk Modulus
- Density Exponent
- Maximum Density Ratio Limit
- Minimum Density Ratio Limit

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 8.18: Compressible Liquid Density Settings Panel



Note:

- Ansys Fluent automatically fills user input values for certain materials based on open literature. If data is not available Fluent will fill in values of zero. Therefore, you must verify that suitable values are entered for your application.
- When Fluent automatically fills in values, the default value of the density exponent is set close to the value for water-liquid.
- The value for the density exponent is generally found by calibrating against data for density, pressure, bulk modulus, and speed of sound. If the value is unknown, it is recommended that you use a value of 1, which corresponds to a linear relationship between density and pressure.

You can set the compressible-liquid density method using the following text command:

`define` → `materials` → `change-create`

In the text command interface, set the `change Density?` option to `yes`, and set `new method [constant]` to `compressible-liquid` as shown below:

```
/define/materials> change-create

material-name> water-liquid
material name [water-liquid]
water-liquid is a fluid
```

8.3.4.2. Compressible Liquid Density Method Availability

The compressible liquid density method is available with fluid materials or with components of a mixture material having the density method set to `volume-weighted-mixing-law` for both single and multiphase cases.

This method is not available with the density-based solver.

8.3.5. Density as a Profile Function of Temperature

If you are modeling a problem that involves heat transfer, you can define the density as a function of temperature. Three types of functions are available:

- piecewise-linear:

$$\rho(T)=\rho_n+\frac{\rho_{n+1}-\rho_n}{T_{n+1}-T_n}(T-T_n) \tag{8.13}$$

- piecewise-polynomial:

$$\begin{aligned}&\text{for } T_{min,1}\le T<T_{max,1}: \rho(T)=A_1+A_2T+A_3T^2+\ldots\\&\text{for } T_{min,2}\le T<T_{max,2}: \rho(T)=B_1+B_2T+B_3T^2+\ldots\end{aligned} \tag{8.14}$$

- polynomial:

$$\rho(T)=A_1+A_2T+A_3T^2+\ldots \tag{8.15}$$

For one of the these methods, select **piecewise-linear**, **piecewise-polynomial**, or **polynomial** in the **Density** drop-down list. You can enter the data pairs (T_n,ρ_n), ranges and coefficients, or coefficients that describe these functions using the Create/Edit Materials Dialog Box (p. 4833), as described in Defining Properties Using Temperature-Dependent Functions (p. 1590).

8.3.6. Incompressible Ideal Gas Law

In Ansys Fluent, if you choose to define the density using the ideal gas law for an incompressible flow, the solver will compute the density as

$$\rho=\frac{p_{op}}{\frac{R}{M_w}T} \tag{8.16}$$

where,

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

R = the universal gas constant

M_w = the molecular weight of the gas

p_{op} = the operating pressure

In this form, the density depends only on the operating pressure and not on the local relative pressure field.

8.3.6.1. Density Inputs for the Incompressible Ideal Gas Law

The inputs for the incompressible ideal gas law are as follows:

1. Enable the ideal gas law for an incompressible fluid by choosing **incompressible-ideal-gas** from the drop-down list to the right of **Density** in the Create/Edit Materials Dialog Box (p. 4833).

   Specify the incompressible ideal gas law individually for each material that you want to use it for. See Composition-Dependent Density for Multicomponent Mixtures (p. 1606) for information on specifying the incompressible ideal gas law for mixtures.

2. Set the operating pressure by defining the **Operating Pressure** in the Operating Conditions Dialog Box (p. 4926).

   Setup → **Cell Zone Conditions** → **Operating Conditions...**

   Important:

   By default, operating pressure is set to 101325 Pa. The input of the operating pressure is of great importance when you are computing density with the ideal gas law. See Operating Pressure (p. 1651) for recommendations on setting appropriate values for the operating pressure.

3. Set the molecular weight of the homogeneous or single-component fluid (if no chemical species transport equations are to be solved), or the molecular weights of each fluid material (species) in a multicomponent mixture. For each fluid material, enter the value of the **Molecular Weight** in the Create/Edit Materials Dialog Box (p. 4833).

8.3.7. Ideal Gas Law for Compressible Flows

For compressible flows, the gas law is as following:

$$\rho = \frac{p_{op} + p}{\frac{R}{M_w} T} \tag{8.17}$$

where,

p = the local relative (or gauge) pressure predicted by Ansys Fluent

p_{op} = the operating pressure

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8.3.7.1. Density Inputs for the Ideal Gas Law for Compressible Flows

The inputs for the ideal gas law are as follows:

1. Enable the ideal gas law for a compressible fluid by choosing **ideal-gas** from the drop-down list to the right of **Density** in the Create/Edit Materials Dialog Box (p. 4833).

   Specify the ideal gas law individually for each material that you want to use it for. See Composition-Dependent Density for Multicomponent Mixtures (p. 1606) for information on specifying the ideal gas law for mixtures.

2. Set the operating pressure by defining the **Operating Pressure** in the Operating Conditions Dialog Box (p. 4926).

   Setup → **Cell Zone Conditions** → **Operating Conditions...**

   Important:

   The input of the operating pressure is of great importance when you are computing density with the ideal gas law. Equation 8.17 (p. 1605) notes that the operating pressure is added to the relative pressure field computed by the solver, yielding the absolute static pressure. See Operating Pressure (p. 1651) for recommendations on setting appropriate values for the operating pressure. By default, operating pressure is set to 101325 Pa.

3. Set the molecular weight of the homogeneous or single-component fluid (if no chemical species transport equations are to be solved), or the molecular weights of each fluid material (species) in a multicomponent mixture. For each fluid material, enter the value of the **Molecular Weight** in the Create/Edit Materials Dialog Box (p. 4833).

8.3.8. Composition-Dependent Density for Multicomponent Mixtures

If you are solving species transport equations, set properties for the mixture material and for the constituent fluids (species), as described in detail in Defining Properties for the Mixture and Its Constituent Species (p. 2372). To define a composition-dependent density for a mixture, do the following:

1. Select the density method:

   - For non-ideal-gas mixtures, you can select the **volume-weighted-mixing-law** method for the mixture material in the drop-down list to the right of **Density** in the Create/Edit Materials Dialog Box (p. 4833).

   - For compressible multicomponent mixtures where the individual species may be real fluids (using Real Gas Property (RGP) tables) and/or ideal gas, you can select the **compressible-volume-weighted** method for the mixture material in the drop-down list to the right of **Density** in the Create/Edit Materials Dialog Box (p. 4833). This option is recommended when the mixture contains

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

at least one RGP species. However, when all species are ideal gas, then you should use the **ideal-gas** method.

Note:

Prior to using this method, you need to create one or several materials for the species using RGP tables as described in Using Real Gas Property (RGP) Table Files (p. 1705).

The **compressible-volume-weighted** density method uses the same formula for density as the **volume-weighted-mixing-law**. The difference is the thermodynamic property algorithms used by the solver. That is, the compressible-volume-weighted method is intended for compressible species, including real gas, whereas the volume-weighted-mixing-law method is intended for incompressible species.

- If you are modeling compressible flow, you can select **ideal-gas** for the mixture material in the drop-down list to the right of **Density** in the Create/Edit Materials Dialog Box (p. 4833).
- If you are modeling incompressible flow using the ideal gas law, you can select **incompressible-ideal-gas** for the mixture material in the **Density** drop-down list in the Create/Edit Materials Dialog Box (p. 4833).
- If you have a user-defined function that you want to use to model the density, you can choose either the **user-defined** method or the **user-defined-mixing-law** method for the mixture material in the drop-down list.

The only difference between the **user-defined-mixing-law** and the **user-defined** option for specifying density, viscosity and thermal conductivity of mixture materials, is that with the **user-defined-mixing-law** option, the individual properties of the species materials can also be specified. (Note that only the constant, the polynomial methods and the user-defined methods are available.)

2. Define the remaining property methods for the mixture material as appropriate for your case.
3. Click **Change/Create**.
4. If you have selected **volume-weighted-mixing-law**, define the density for each of the fluid materials that make up the mixture. You may define constant or compressible-liquid or (if applicable) temperature-dependent densities for the individual species.
5. If you have selected **compressible-volume-weighted**, double-check settings for each of the species materials.
6. If you selected **user-defined-mixing-law**, define the density for each of the fluid materials that make up the mixture. You may define constant, or (if applicable) temperature-dependent densities, or user-defined densities for the individual species. More information on defining properties with user-defined functions can be found in the Fluent Customization Manual.

If you are modeling a non-ideal-gas mixture, Ansys Fluent will compute the mixture density as

$$\rho = \frac{1}{\sum_i \frac{Y_i}{\rho_i}} \tag{8.18}$$

where Y_i is the mass fraction and ρ_i is the density of species i.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For compressible flows, the gas law has the following form:

$$\rho = \frac{p_{op} + p}{RT \sum_i \frac{Y_i}{M_{w,i}}} \tag{8.19}$$

where,

p = the local relative (or gauge) pressure predicted by Ansys Fluent

R = the universal gas constant

Y_i = the mass fraction of species i

$M_{w,i}$ = the molecular weight of species i

p_{op} = the operating pressure

In Ansys Fluent, if you choose to define the density using the ideal gas law for an incompressible flow, the solver will compute the density as

$$\rho = \frac{p_{op}}{RT \sum_i \frac{Y_i}{M_{w,i}}} \tag{8.20}$$

where,

R = the universal gas constant

Y_i = the mass fraction of species i

$M_{w,i}$ = the molecular weight of species i

p_{op} = the operating pressure

8.4. Viscosity

Ansys Fluent provides several options for definition of the fluid viscosity:

- constant viscosity
- temperature-dependent and/or composition-dependent viscosity
- kinetic theory
- non-Newtonian viscosity
- user-defined function

Each of these input options and the governing physical models are detailed in this section. (User-defined functions are described in the Fluent Customization Manual). In all cases, define the **Viscosity** in the Create/Edit Materials Dialog Box (p. 4833).

Setup → Materials

Viscosities are input as dynamic viscosity (μ) in units of kg/m-s in SI units or lb_m/ft-s in British units. Ansys Fluent does not ask for input of the kinematic viscosity (ν).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For additional information, see the following sections:

8.4.1. Input of Constant Viscosity
8.4.2. Viscosity as a Function of Temperature
8.4.3. Defining the Viscosity Using Kinetic Theory
8.4.4. Defining Viscosity Using Gupta Curve Fits
8.4.5. Composition-Dependent Viscosity for Multicomponent Mixtures
8.4.6. Viscosity for Non-Newtonian Fluids

8.4.1. Input of Constant Viscosity

If you want to define the viscosity of your fluid as a constant, select **constant** in the **Viscosity** drop-down list in the Create/Edit Materials Dialog Box (p. 4833), and enter the value of viscosity for the fluid.

For the default fluid (air), the viscosity is 1.7894×10^{-5} kg/m-s.

8.4.2. Viscosity as a Function of Temperature

If you are modeling a problem that involves heat transfer, you can define the viscosity as a function of temperature. Five types of functions are available.

- piecewise-linear:

$$\mu(T)=\mu_n+\frac{\mu_{n+1}-\mu_n}{T_{n+1}-T_n}(T-T_n) \tag{8.21}$$

- piecewise-polynomial:

$$\begin{aligned}&\text{for } T_{min,1}\le T<T_{max,1}: \mu(T)=A_1+A_2T+A_3T^2+\ldots\\&\text{for } T_{min,2}\le T<T_{max,2}: \mu(T)=B_1+B_2T+B_3T^2+\ldots\end{aligned} \tag{8.22}$$

- polynomial:

$$\mu(T)=A_1+A_2T+A_3T^2+\ldots \tag{8.23}$$

- Sutherland's law
- power law

Important:

The power law described here is different from the non-Newtonian power law described in Viscosity for Non-Newtonian Fluids (p. 1613).

For one of the first three, select **piecewise-linear**, **piecewise-polynomial**, **polynomial** in the **Viscosity** drop-down list and then enter the data pairs (T_n,μ_n), ranges and coefficients, or coefficients that describe these functions Defining Properties Using Temperature-Dependent Functions (p. 1590). For Sutherland's law or the power law, choose **sutherland** or **power-law** respectively in the drop-down list and enter the parameters.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8.4.2.1. Sutherland Viscosity Law

Sutherland's viscosity law resulted from a kinetic theory by Sutherland (1893) using an idealized intermolecular-force potential. The formula is specified using two or three coefficients.

Sutherland's law with two coefficients has the form

$$\mu=\frac{C_1 T^{3/2}}{T+C_2} \tag{8.24}$$

where,

μ = the viscosity in kg/m-s

T = the static temperature in K

C_1 and C_2 = the coefficients

For air at moderate temperatures and pressures, $C_1=1.458\times10^{-6}$ kg/m-s-$K^{1/2}$, and $C_2=110.4$ K.

Sutherland's law with three coefficients has the form

$$\mu=\mu_0\left(\frac{T}{T_0}\right)^{3/2}\frac{T_0+S}{T+S} \tag{8.25}$$

where,

μ = the viscosity in kg/m-s

T = the static temperature in K

μ_0 = reference value in kg/m-s

T_0 = reference temperature in K

S = an effective temperature in K (Sutherland constant)

For air at moderate temperatures and pressures, $\mu_0=1.716\times10^{-5}$ kg/m-s, T_0 = 273.11 K, and S = 110.56 K.

8.4.2.1.1. Inputs for Sutherland's Law

To use Sutherland's law, choose **sutherland** in the drop-down list to the right of **Viscosity**. The Sutherland Law Dialog Box (p. 4864) will open, and you can enter the coefficients as follows:

1. Select the **Two Coefficient Method** or the **Three Coefficient Method**.

   Important:

   Use SI units if you choose the two-coefficient method.

2. For the **Two Coefficient Method**, set **C1** and **C2**. For the **Three Coefficient Method**, set the **Reference Viscosity** μ_0, the **Reference Temperature** T_0, and the **Effective Temperature** S.

3. To visualize your profile, ensure the correct **Primary Independent Variable** is selected from the drop-down list, and enter a value for the **Min** and **Max**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8.4.2.2. Power-Law Viscosity Law

Another common approximation for the viscosity of dilute gases is the power-law form. For dilute gases at moderate temperatures, this form is considered to be slightly less accurate than Sutherland's law.

A power-law viscosity law with two coefficients has the form

$$\mu = BT^n \tag{8.26}$$

where,

μ = the viscosity in kg/m-s

T = the static temperature in K

B = a dimensional coefficient

For air at moderate temperatures and pressures, $B = 4.093 \times 10^{-7}$, and $n = 2/3$.

A power-law viscosity law with three coefficients has the form

$$\mu = \mu_0 \left(\frac{T}{T_0} \right)^n \tag{8.27}$$

where,

μ = the viscosity in kg/m-s

T = the static temperature in K

T_0 = a reference value in K

μ_0 = a reference value in kg/m-s

For air at moderate temperatures and pressures, $\mu_0 = 1.716 \times 10^{-5}$ kg/m-s, $T_0 = 273$ K, and $n = 2/3$.

Important:

The non-Newtonian power law for viscosity is described in Viscosity for Non-Newtonian Fluids (p. 1613).

8.4.2.2.1. Inputs for the Power Law

To use the power law, choose **power-law** in the drop-down list to the right of **Viscosity**. The Power Law Dialog Box (p. 4865) will open, and you can enter the coefficients as follows:

1. Select the **Two Coefficient Method** or the **Three Coefficient Method**.

Important:

Note that you must use SI units if you choose the two-coefficient method.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. For the **Two Coefficient Method**, set **B** and the **Temperature Exponent** n. For the **Three Coefficient Method**, set the **Reference Viscosity** μ_0, the **Reference Temperature** T_0, and the **Temperature Exponent** n.

3. To visualize your profile, ensure the correct **Primary Independent Variable** is selected from the drop-down list, and enter a value for the **Min** and **Max**.

8.4.3. Defining the Viscosity Using Kinetic Theory

If you are using the ideal gas law (as described in Density (p. 1598)), you have the option to define the fluid viscosity using kinetic theory as

$$\mu = 2.67 \times 10^{-6} \frac{\sqrt{M_w T}}{\sigma^2 \Omega_\mu} \tag{8.28}$$

where,

μ is in units of kg/m-s,

T is in units of Kelvin

σ is in units of Angstroms

$\Omega_\mu = \Omega_\mu\left(T^*\right)$

M_w is the molecular weight

where

$$T^* = \frac{T}{\left(\varepsilon / k_B\right)} \tag{8.29}$$

The Lennard-Jones parameters, σ and ε / k_B, are inputs to the kinetic theory calculation that you supply by selecting **kinetic-theory** from the drop-down list to the right of **Viscosity** in the Create/Edit Materials Dialog Box (p. 4833). The solver will use these kinetic theory inputs in Equation 8.28 (p. 1612) to compute the fluid viscosity. See Kinetic Theory Parameters (p. 1650) for details about these inputs.

8.4.4. Defining Viscosity Using Gupta Curve Fits

When simulating hypersonic flows using the default one-temperature approach, Fluent offers Gupta curve fits that are applicable for air mixtures with temperatures up to 30 000 K. For details, see Modeling Transport Properties Using Gupta Curve Fits (p. 2299).

8.4.5. Composition-Dependent Viscosity for Multicomponent Mixtures

If you are modeling a flow that includes more than one chemical species (multicomponent flow), you have the option to define a composition-dependent viscosity. (Note that you can also define the viscosity of the mixture as a constant value or a function of temperature.)

To define a composition-dependent viscosity for a mixture, follow these steps:

1. For the mixture material, choose **mass-weighted-mixing-law** or, if you are using the ideal gas law for density, **ideal-gas-mixing-law** in the drop-down list to the right of **Viscosity**. If you have a user-defined function that you want to use to model the viscosity, you can choose either the

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

user-defined method or the **user-defined-mixing-law** method for the mixture material in the drop-down list.

2. Click **Change/Create**.

3. Define the viscosity for each of the fluid materials that make up the mixture. You may define constant or (if applicable) temperature-dependent viscosities for the individual species. You may also use kinetic theory for the individual viscosities, or specify a non-Newtonian viscosity, if applicable.

4. If you selected **user-defined-mixing-law**, define the viscosity for each of the fluid materials that make up the mixture. You may define constant, or (if applicable) temperature-dependent viscosities, or user-defined viscosities for the individual species. More information on defining properties with user-defined functions can be found in the Fluent Customization Manual.

   The only difference between the **user-defined-mixing-law** and the **user-defined** option for specifying density, viscosity and thermal conductivity of mixture materials, is that with the **user-defined-mixing-law** option, the individual properties of the species materials can also be specified. (Note that only the constant, the polynomial methods and the user-defined methods are available.)

If you are using the ideal gas law, the solver will compute the mixture viscosity based on kinetic theory as

$$\mu = \sum_i \frac{X_i \mu_i}{\sum_j X_j \phi_{ij}} \tag{8.30}$$

where

$$\phi_{ij} = \frac{\left[1 + \left(\frac{\mu_i}{\mu_j}\right)^{1/2} \left(\frac{M_{w,j}}{M_{w,i}}\right)^{1/4}\right]^2}{\left[8\left(1 + \frac{M_{w,i}}{M_{w,j}}\right)\right]^{1/2}} \tag{8.31}$$

and X_i is the mole fraction of species i.

For non-ideal gas mixtures, the mixture viscosity is computed based on a simple mass fraction average of the pure species viscosities:

$$\mu = \sum_i Y_i \mu_i \tag{8.32}$$

8.4.6. Viscosity for Non-Newtonian Fluids

For incompressible Newtonian fluids, the shear stress is proportional to the rate-of-deformation tensor $\overline{\overline{D}}$:

$$\overline{\overline{\tau}} = \mu \overline{\overline{D}} \tag{8.33}$$

where $\overline{\overline{D}}$ is defined by

$$\overline{\overline{D}} = \left(\frac{\partial u_j}{\partial x_i} + \frac{\partial u_i}{\partial x_j}\right) \tag{8.34}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

and μ is the viscosity, which is independent of $\overline{\overline{D}}$.

For some non-Newtonian fluids, the shear stress can similarly be written in terms of a non-Newtonian viscosity η:

$$\overline{\overline{\tau}}=\eta\left(\overline{\overline{D}}\right)\overline{\overline{D}} \tag{8.35}$$

In general, η is a function of all three invariants of the rate-of-deformation tensor $\overline{\overline{D}}$. However, in the non-Newtonian models available in Ansys Fluent, η is considered to be a function of the shear rate $\dot{\gamma}$ only. $\dot{\gamma}$ is related to the second invariant of $\overline{\overline{D}}$ and is defined as

$$\dot{\gamma}=\sqrt{\frac{1}{2}\overline{\overline{D}}:\overline{\overline{D}}} \tag{8.36}$$

8.4.6.1. Temperature Dependent Viscosity

If the flow is non-isothermal, then the temperature dependence on the viscosity can be included along with the shear rate dependence. In this case, the total viscosity consists of two parts and is calculated as

$$\mu=\eta\left(\dot{\gamma}\right)H\left(T\right) \tag{8.37}$$

where H(T) is the temperature dependence, known as the Arrhenius law.

$$H\left(T\right)=exp\left[\alpha\left(\frac{1}{T-T_0}-\frac{1}{T_\alpha-T_0}\right)\right] \tag{8.38}$$

where α is the ratio of the activation energy to the thermodynamic constant and T_α is a reference temperature for which H(T) = 1. T_0, which is the temperature shift, is set to 0 by default, and corresponds to the lowest temperature that is thermodynamically acceptable. Therefore T_α and T_0 are absolute temperatures. Temperature dependence is only included when the energy equation is enabled. Set the parameter α to 0 when you want temperature dependence to be ignored, even when the energy equation is solved.

Ansys Fluent provides four options for modeling non-Newtonian flows:

- power law
- Carreau model for pseudo-plastics
- Cross model
- Herschel-Bulkley model for Bingham plastics

Important:

- Note that the models listed above are not available when modeling turbulent flow.
- Note that the non-Newtonian power law described below is different from the power law described in Power-Law Viscosity Law (p. 1611).
- Non-Newtonian model based on single fluid formulation is available for the mixture model and it is recommended that this should be attached to the primary phase.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Appropriate values for the input parameters for these models can be found in the literature (for example, [155] (p. 5664)).

8.4.6.2. Power Law for Non-Newtonian Viscosity

If you choose **non-newtonian-power-law** in the drop-down list to the right of **Viscosity**, non-Newtonian flow will be modeled according to the following power law for the non-Newtonian viscosity:

$$\eta = k\dot{\gamma}^{n-1}H(T) \tag{8.39}$$

where k and n are input parameters. k is a measure of the average viscosity of the fluid (the consistency index); n is a measure of the deviation of the fluid from Newtonian (the power-law index). The value of n determines the class of the fluid:

$n=1 \rightarrow$ Newtonian fluid

$n>1 \rightarrow$ shear-thickening (dilatant fluids)

$n<1 \rightarrow$ shear-thinning (pseudo-plastics)

8.4.6.2.1. Inputs for the Non-Newtonian Power Law

To use the non-Newtonian power law, choose **non-newtonian-power-law** in the drop-down list to the right of **Viscosity**. The Non-Newtonian Power Law Dialog Box (p. 4867) will open, and you can choose between **Shear Rate Dependent** and **Shear Rate and Temperature Dependent**. Enter the **Consistency Index** k, **Power-Law Index** n, **Minimum** and **Maximum Viscosity Limit**, **Reference Temperature** T_{alpha}, and **Activation Energy/R**, α, which is the ratio of the activation energy to the thermodynamic constant.

8.4.6.3. The Carreau Model for Pseudo-Plastics

The power law model described in Equation 8.39 (p. 1615) results in a fluid viscosity that varies with shear rate. For $\dot{\gamma} \rightarrow 0$, $\eta \rightarrow \eta_0$, and for $\dot{\gamma} \rightarrow \infty$, $\eta \rightarrow \eta_\infty$, where η_0 and η_∞ are, respectively, the upper and lower limiting values of the fluid viscosity.

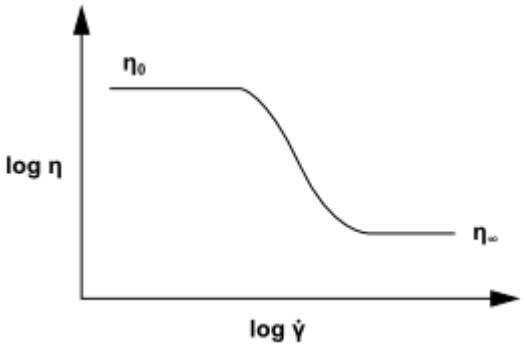
The Carreau model attempts to describe a wide range of fluids by the establishment of a curve-fit to piece together functions for both Newtonian and shear-thinning ($n < 1$) non-Newtonian laws. In the Carreau model, the viscosity is

$$\eta = H(T)\left(\eta_\infty + \left(\eta_0 - \eta_\infty\right)\left[1+\gamma^2\lambda^2\right]^{(n-1)/2}\right) \tag{8.40}$$

and the parameters n, λ, T_α, η_0, and η_∞ are dependent upon the fluid. λ is the time constant, n is the power-law index (as described above for the non-Newtonian power law), η_0 and η_∞ are, respectively, the zero- and infinite-shear viscosities, T_α is the reference temperature, and α is the ratio of the activation energy to thermodynamic constant. Figure 8.19: Variation of Viscosity with Shear Rate According to the Carreau Model (p. 1616) shows how viscosity is limited by η_0 and η_∞ at low and high shear rates.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

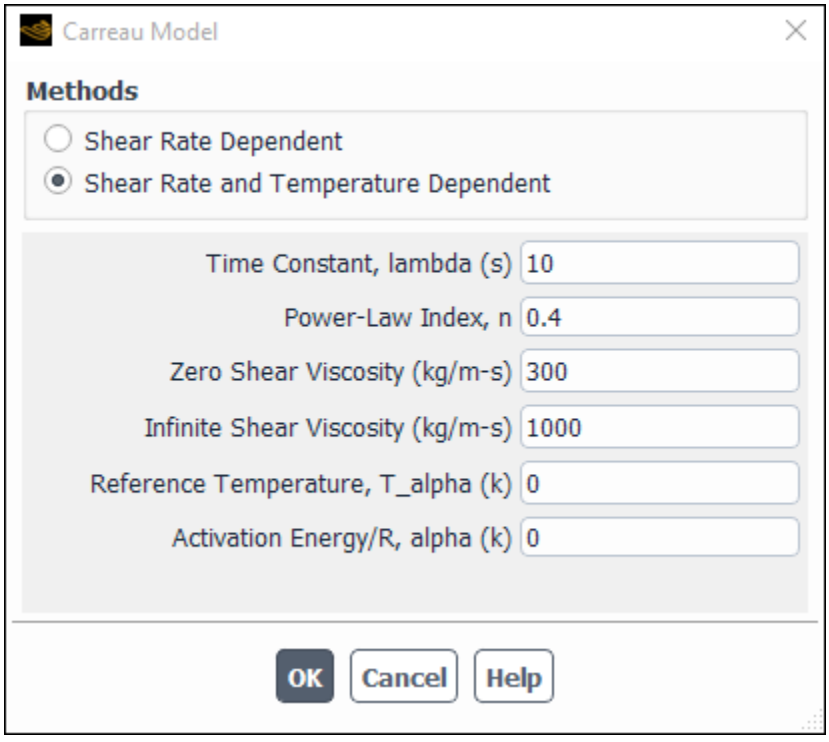
Figure 8.19: Variation of Viscosity with Shear Rate According to the Carreau Model



8.4.6.3.1. Inputs for the Carreau Model

To use the Carreau model, choose **carreau** in the drop-down list to the right of **Viscosity**. The Carreau Model Dialog Box (p. 4868) will open, and you can choose between **Shear Rate Dependent** and **Shear Rate and Temperature Dependent**. Enter the **Time Constant** λ, **Power-Law Index** n, **Reference Temperature** T_α, **Zero Shear Viscosity** η_0, **Infinite Shear Viscosity** η_∞, and **Activation Energy/R** α.

Figure 8.20: The Carreau Model Dialog Box



8.4.6.4. Cross Model

The Cross model for viscosity is:

$$\eta = H(T)\frac{\eta_0}{1+(\lambda\dot{\gamma})^{1-n}} \tag{8.41}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where,

η_0 = zero-shear-rate viscosity

λ = natural time (that is, inverse of the shear rate at which the fluid changes from Newtonian to power-law behavior)

n = power-law index

The Cross model is commonly used to describe the low-shear-rate behavior of the viscosity.

8.4.6.4.1. Inputs for the Cross Model

To use the Cross model, choose **cross** in the drop-down list to the right of **Viscosity**. The Cross Model Dialog Box (p. 4869) will open, and you can choose between **Shear Rate Dependent** and **Shear Rate and Temperature Dependent**. Enter the **Zero Shear Viscosity** η_0, **Time Constant** λ, **Power-Law Index** n, **Reference Temperature** T_α, and **Activation Energy/R**, α, which is the ratio of the activation energy to the thermodynamic constant.

8.4.6.5. Herschel-Bulkley Model for Bingham Plastics

The power law model described above is valid for fluids for which the shear stress is zero when the strain rate is zero. Bingham plastics are characterized by a nonzero shear stress when the strain rate is zero.

$$\bar{\bar{\tau}} = \bar{\bar{\tau}}_0 + \eta \bar{\bar{D}} \tag{8.42}$$

where τ_0 is the yield stress:

- For $\tau < \tau_0$, the material remains rigid.
- For $\tau > \tau_0$, the material flows as a power-law fluid.

The Herschel-Bulkley model combines the effects of Bingham and power-law behavior in a fluid. For low strain rates ($\dot{\gamma} < \tau_0 / \mu_0$), the "rigid" material acts like a very viscous fluid with viscosity μ_0. As the strain rate increases and the yield stress threshold, τ_0, is passed, the fluid behavior is described by a power law.

For $\dot{\gamma} > \dot{\gamma}_c$

$$\eta = \frac{\tau_0}{\dot{\gamma}} + k\dot{\gamma}^{n-1} \tag{8.43}$$

For $\dot{\gamma} < \dot{\gamma}_c$

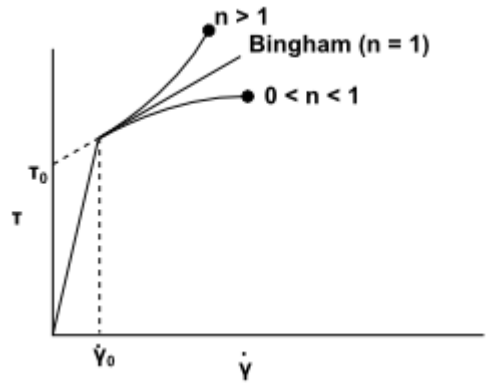
$$\eta = \frac{\tau_0\left(2 - \frac{\dot{\gamma}}{\dot{\gamma}_c}\right)}{\dot{\gamma}_c} + k\left(\dot{\gamma}_c\right)^{n-1}\left[(2-n) + (n-1)\frac{\dot{\gamma}}{\dot{\gamma}_c}\right] \tag{8.44}$$

where k is the consistency index, and n is the power-law index.

Figure 8.21: Variation of Shear Stress with Shear Rate According to the Herschel-Bulkley Model (p. 1618) shows how shear stress (τ) varies with shear rate ($\dot{\gamma}$) for the Herschel-Bulkley model.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 8.21: Variation of Shear Stress with Shear Rate According to the Herschel-Bulkley Model



If you choose the Herschel-Bulkley model for Bingham plastics, Equation 8.43 (p. 1617) will be used to determine the fluid viscosity.

The Herschel-Bulkley model is commonly used to describe materials such as concrete, mud, dough, and toothpaste, for which a constant viscosity after a critical shear stress is a reasonable assumption. In addition to the transition behavior between a flow and no-flow regime, the Herschel-Bulkley model can also exhibit a shear-thinning or shear-thickening behavior depending on the value of n.

8.4.6.5.1. Inputs for the Herschel-Bulkley Model

To use the Herschel-Bulkley model, choose **herschel-bulkley** in the drop-down list to the right of **Viscosity**. The Herschel-Bulkley Dialog Box (p. 4870) will open, and you can choose between **Shear Rate Dependent** and **Shear Rate and Temperature Dependent**. Enter the **Consistency Index** k, **Power-Law Index** n, **Yield Stress Threshold** τ_0, **Critical Shear Rate** $\dot{\gamma}_c$, **Reference Temperature** T_α, and the ratio of the activation energy to thermodynamic constant α, **Activation Energy/R**.

8.5. Thermal Conductivity

The thermal conductivity must be defined when heat transfer is active. You must define thermal conductivity when you are modeling energy and viscous flow.

Ansys Fluent provides several options for definition of the thermal conductivity:

- constant thermal conductivity
- temperature- and/or composition-dependent thermal conductivity
- kinetic theory
- anisotropic (anisotropic, biaxial, orthotropic, cylindrical orthotropic, principal axes and principal values, user-defined anisotropic) (for solid materials only)
- user-defined

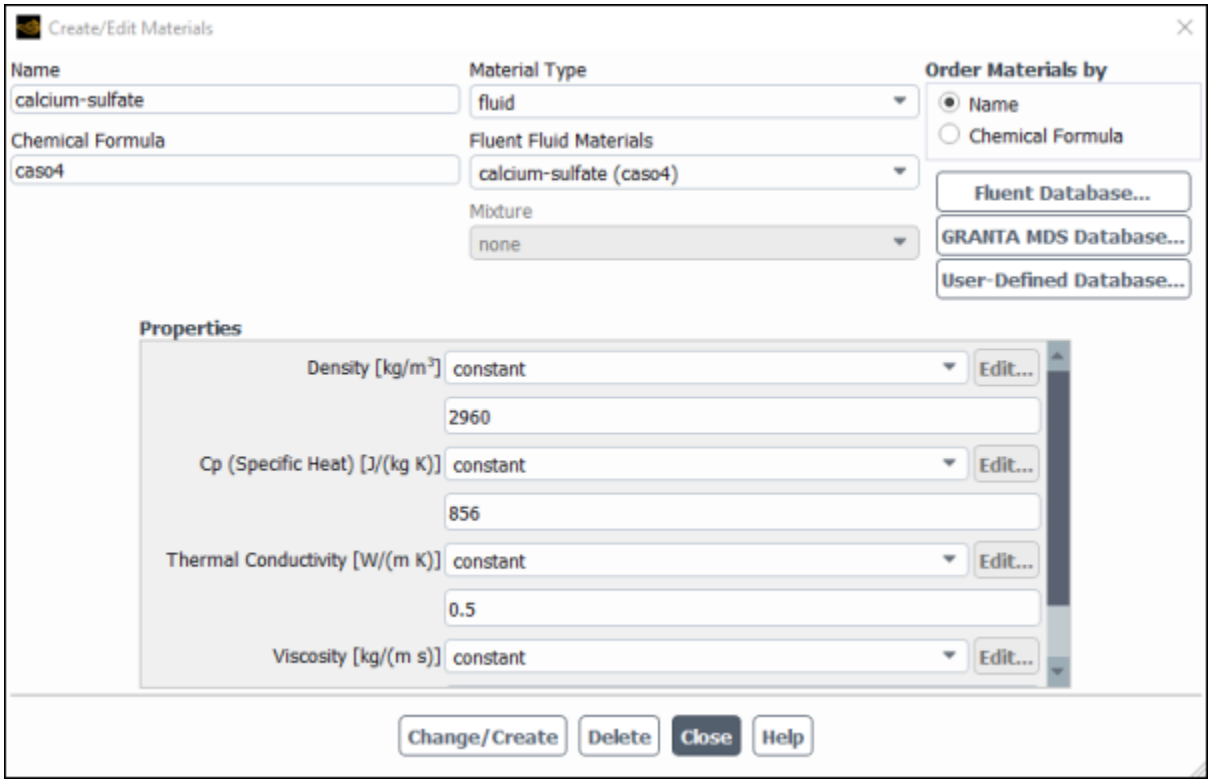
Each of these input options and the governing physical models are detailed in this section. User-defined functions (UDFs) are described in the Fluent Customization Manual.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In all cases, you will define the **Thermal Conductivity** in the Create/Edit Materials Dialog Box (p. 4833) (Figure 8.22: The Create/Edit Materials Dialog Box (p. 1619)).

Setup → Materials → Create/Edit...

Figure 8.22: The Create/Edit Materials Dialog Box



Thermal conductivity is defined in units of W/m-K in SI units or BTU/hr-ft-°R in British units.

For additional information, see the following sections:

8.5.1. Constant Thermal Conductivity

8.5.2. Thermal Conductivity as a Function of Temperature

8.5.3. Thermal Conductivity Using Kinetic Theory

8.5.4. Defining Thermal Conductivity Using Gupta Curve Fits

8.5.5. Composition-Dependent Thermal Conductivity for Multicomponent Mixtures

8.5.6. Anisotropic Thermal Conductivity for Solids

8.5.1. Constant Thermal Conductivity

If you want to define the thermal conductivity as a constant, check that **constant** is selected in the drop-down list to the right of **Thermal Conductivity** in the Create/Edit Materials Dialog Box (p. 4833) (Figure 8.22: The Create/Edit Materials Dialog Box (p. 1619)), and enter the value of thermal conductivity for the material.

For the default fluid (air), the thermal conductivity is 0.0242 W/m-K.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8.5.2. Thermal Conductivity as a Function of Temperature

You can also choose to define the thermal conductivity as a function of temperature. Three types of functions are available:

- piecewise-linear:

$$k(T) = k_n + \frac{k_{n+1} - k_n}{T_{n+1} - T_n}(T - T_n) \tag{8.45}$$

- piecewise-polynomial:

$$\begin{aligned} &\text{for } T_{min,1} \le T < T_{max,1}: k(T) = A_1 + A_2 T + A_3 T^2 + \ldots \\ &\text{for } T_{min,2} \le T < T_{max,2}: k(T) = B_1 + B_2 T + B_3 T^2 + \ldots \end{aligned} \tag{8.46}$$

- polynomial:

$$k(T) = A_1 + A_2 T + A_3 T^2 + \ldots \tag{8.47}$$

You can input the data pairs (T_n, k_n), ranges and coefficients A_i and B_i, or coefficients A_i that describe these functions using the Create/Edit Materials Dialog Box (p. 4833), as described in Defining Properties Using Temperature-Dependent Functions (p. 1590).

8.5.3. Thermal Conductivity Using Kinetic Theory

If you are using the ideal gas law (as described in Density (p. 1598)), you have the option to define the thermal conductivity using kinetic theory as

$$k = \frac{15}{4}\frac{R}{M_w}\mu\left[\frac{4}{15}\frac{c_p M_w}{R} + \frac{1}{3}\right] \tag{8.48}$$

where R is the universal gas constant, M_w is the molecular weight, μ is the material's specified or computed viscosity, and c_p is the material's specified or computed specific heat capacity.

To enable the use of this equation for calculating thermal conductivity, select **kinetic-theory** from the drop-down list to the right of **Thermal Conductivity** in the Create/Edit Materials Dialog Box (p. 4833). The solver will use Equation 8.48 (p. 1620) to compute the thermal conductivity.

8.5.4. Defining Thermal Conductivity Using Gupta Curve Fits

When simulating hypersonic flows using the default one-temperature approach, Fluent offers Gupta curve fits that are applicable for air mixtures with temperatures up to 30 000 K. For details, see Modeling Transport Properties Using Gupta Curve Fits (p. 2299).

8.5.5. Composition-Dependent Thermal Conductivity for Multicomponent Mixtures

If you are modeling a flow that includes more than one chemical species (multicomponent flow), you have the option to define a composition-dependent thermal conductivity. (Note that you can also define the thermal conductivity of the mixture as a constant value or a function of temperature, or using kinetic theory.)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To define a composition-dependent thermal conductivity for a mixture, follow these steps:

1. For the mixture material, choose **mass-weighted-mixing-law** or, if you are using the ideal gas law, **ideal-gas-mixing-law** in the drop-down list to the right of **Thermal Conductivity**. If you have a user-defined function that you want to use to model the thermal conductivity, you can choose either the **user-defined** method or the **user-defined-mixing-law** method for the mixture material in the drop-down list.

   The only difference between the **user-defined-mixing-law** and the **user-defined** option for specifying density, viscosity and thermal conductivity of mixture materials, is that with the **user-defined-mixing-law** option, the individual properties of the species materials can also be specified. Note that only the constant, the polynomial methods and the user-defined methods are available.

   Important:

   If you use **ideal-gas-mixing-law** for the thermal conductivity of a mixture, you must use **ideal-gas-mixing-law** or **mass-weighted-mixing-law** for viscosity, because these two viscosity specification methods are the only ones that allow specification of the component viscosities, which are used in the ideal gas law for thermal conductivity (Equation 8.49 (p. 1621)).

2. Click **Change/Create**.

3. Define the thermal conductivity for each of the fluid materials that make up the mixture. You may define constant or (if applicable) temperature-dependent thermal conductivities for the individual species. You may also use kinetic theory for the individual thermal conductivities, if applicable.

4. If you selected **user-defined-mixing-law**, define the thermal conductivity for each of the fluid materials that make up the mixture. You may define constant, or (if applicable) temperature-dependent thermal conductivities, or user-defined thermal conductivities for the individual species. More information about defining properties with user-defined functions can be found in the Fluent Customization Manual.

If you are using the ideal gas law, the solver will compute the mixture thermal conductivity based on kinetic theory as

$$k = \sum_i \frac{X_i k_i}{\sum_j X_j \phi_{ij}} \tag{8.49}$$

where

$$\phi_{ij} = \frac{\left[1 + \left(\frac{\mu_i}{\mu_j}\right)^{1/2} \left(\frac{M_{w,j}}{M_{w,i}}\right)^{1/4}\right]^2}{\left[8\left(1 + \frac{M_{w,i}}{M_{w,j}}\right)\right]^{1/2}} \tag{8.50}$$

and X_i is the mole fraction of species i.

For non-ideal gases, the mixture thermal conductivity is computed based on a simple mass fraction average of the pure species conductivities:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$k = \sum_i Y_i k_i \tag{8.51}$$

8.5.6. Anisotropic Thermal Conductivity for Solids

The anisotropic conductivity options in Ansys Fluent solves the conduction equation in solid zones and shells with the thermal conductivity specified as a matrix. The heat flux vector is written as

$$q_i = -k_{ij} \frac{\partial T}{\partial x_j} \tag{8.52}$$

The following options are available for defining anisotropic thermal conductivity in Ansys Fluent. These are discussed below.

- anisotropic
- biaxial (available for shells only)
- orthotropic
- cylindrical orthotropic
- principal axes and principal values
- user-defined anisotropic

Note:

When postprocessing solid material properties, the Thermal Conductivity will be displayed as zero if an anisotropic thermal conductivity model is being used for a solid material. However, additional postprocessing variables are available to display the components of the thermal conductivity matrix: **Thermal Conductivity XX | XY | XZ | YX | YY | YZ | ZX | ZY | ZZ**. *When orthotropic thermal conductivity is used, the thermal conductivity matrix is symmetric, and the following variables are not made available to avoid redundancy:* ***Thermal Conductivity YX | ZX | ZY***.

Important:

The anisotropic conductivity options are available only with the pressure-based solver; you cannot use them with the density-based solvers.

For cases that have solid zones that use an anisotropic thermal conductivity option, you can change the following settings: you can select the method used to calculate the heat flux (which can affect the calculation robustness and convergence rate); you can select the method used to calculate the temperature gradient (which can affect the simulation speed); and/or you can set the relaxation for the heat flux coefficient (which can improve convergence in certain cases). For details about changing these settings, see Settings for Anisotropic Solid Zones (p. 2143).

8.5.6.1. Anisotropic Thermal Conductivity

For anisotropic diffusion, the thermal conductivity matrix (Equation 8.52 (p. 1622)) is specified as

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$k_{ij}=k\hat{e}_{ij} \tag{8.53}$$

where k is the conductivity and $\hat{e}_{ij}$ is a matrix (2 × 2 for two dimensions and 3 × 3 for three-dimensional problems). Note that $\hat{e}_{ij}$ can be a non-symmetric matrix.

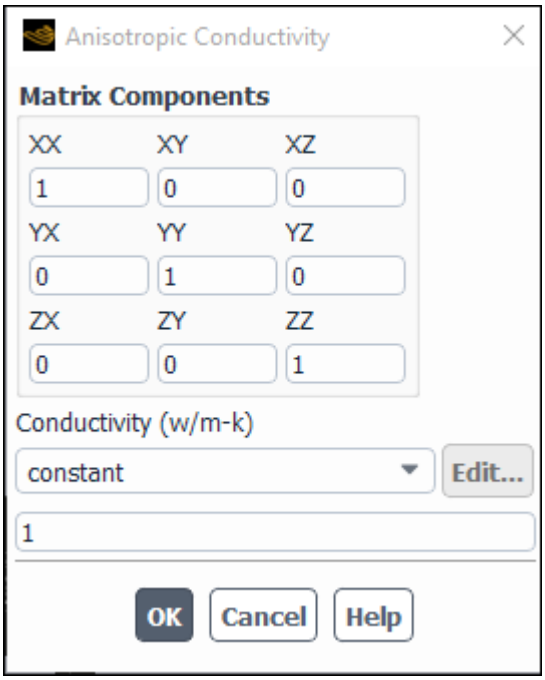
To define anisotropic thermal conductivity for a solid material, select **anisotropic** for **Thermal Conductivity** in the Create/Edit Materials Dialog Box (p. 4833) (Figure 8.22: The Create/Edit Materials Dialog Box (p. 1619)). Note the following:

- If the principal axes of your anisotropic material are not aligned with the global coordinate system of your simulation, it may be easier for you to use one of the following options: if the axes are orthogonal, you can use the **orthotropic** option, as described in Orthotropic Thermal Conductivity (p. 1624); if the axes are not orthogonal, you can use the **principal-axes-values** option, as described in Principal Axes and Principal Values (p. 1628). If you use the **anisotropic** option with unaligned axes, it is your responsibility to transform the thermal conductivity properties into the k_{ij} tensor aligned with the global coordinate system.

- The **anisotropic** option is appropriate when the components of the k_{ij} matrix are constants and do not vary independently; if this is not the case, you can use a UDF to define the matrix and select **user-defined-anisotropic-k**, as described in User-Defined Anisotropic Thermal Conductivity (p. 1630).

Selecting **anisotropic** will open the Anisotropic Conductivity Dialog Box (p. 4876) (Figure 8.23: The Anisotropic Conductivity Dialog Box (p. 1623)).

Figure 8.23: The Anisotropic Conductivity Dialog Box



In the Anisotropic Conductivity Dialog Box (p. 4876), enter the **Matrix Components** of matrix $\hat{e}_{ij}$ and then select the **Conductivity** (k in Equation 8.53 (p. 1623)) to be a **constant**, polynomial function of temperature (**polynomial**, **piecewise-linear**, **piecewise-polynomial**), or **user-defined** function.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

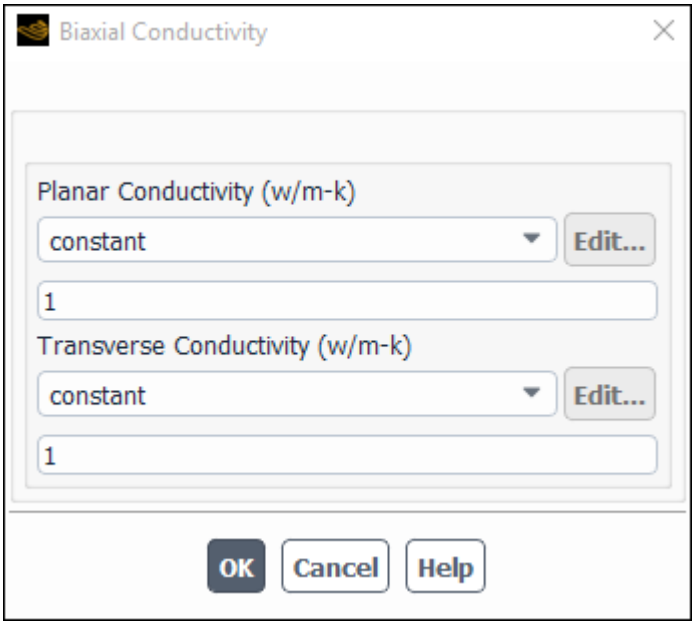
See Constant Thermal Conductivity (p. 1619) and Thermal Conductivity as a Function of Temperature (p. 1620) for details on constants and thermal polynomial functions.

When you select the **user-defined** option, the User-Defined Functions Dialog Box (p. 4863) will open, allowing you to hook a `DEFINE_PROPERTY` UDF *only* if you have previously loaded a compiled UDF library or interpreted the UDF. Otherwise, you will get an error message. Details about user-defined functions can be found in the Fluent Customization Manual.

8.5.6.2. Biaxial Thermal Conductivity

Biaxial thermal conductivity is applicable only for solid materials used for the wall shell conduction model. To define a biaxial thermal conductivity, select **biaxial** in the drop-down list for **Thermal Conductivity** in the Create/Edit Materials Dialog Box (p. 4833). This opens the Biaxial Conductivity Dialog Box (p. 4872) (Figure 8.24: The Biaxial Conductivity Dialog Box (p. 1624)).

Figure 8.24: The Biaxial Conductivity Dialog Box



In the Biaxial Conductivity Dialog Box (p. 4872), both the conductivity normal to the surface of the shell (**Transverse Conductivity**) and the conductivity parallel to the surface of the shell (**Planar Conductivity**) can be defined as **constant**, **polynomial**, **piecewise-linear**, or **piecewise-polynomial**. See Constant Thermal Conductivity (p. 1619) and Thermal Conductivity as a Function of Temperature (p. 1620) for details on these parameters. Note that the **Planar Conductivity** is isotropic. See Figure 15.10: The Conduction Manager Dialog Box (p. 2149).

8.5.6.3. Orthotropic Thermal Conductivity

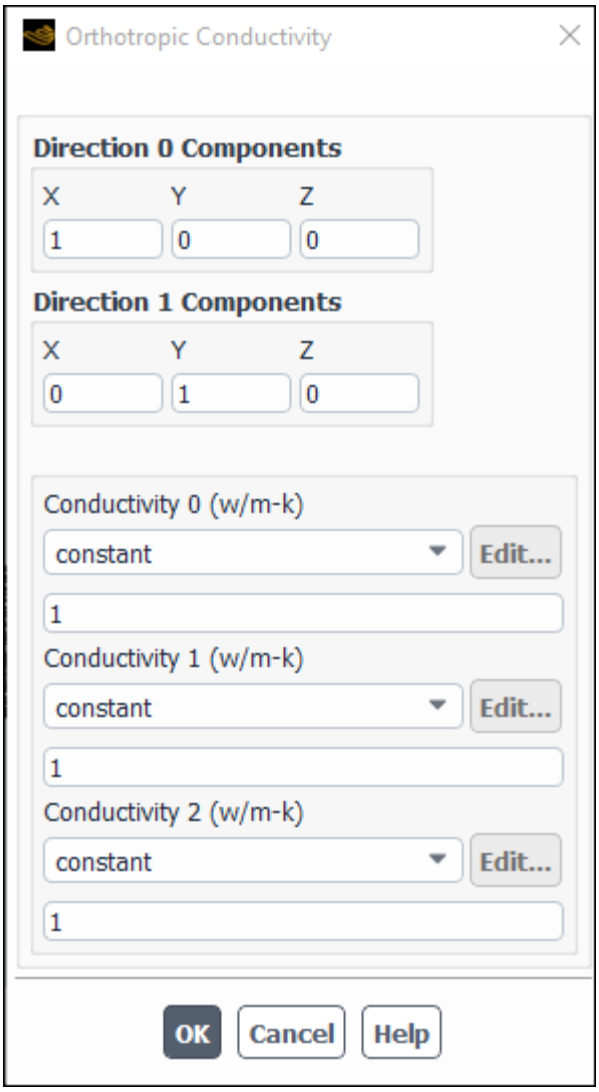
When the orthotropic thermal conductivity is used, the thermal conductivities $\left(k_\xi, k_\eta, k_\zeta\right)$ in the principal directions $\left(\hat{e}_\xi, \hat{e}_\eta, \hat{e}_\zeta\right)$ are specified. The conductivity matrix is then computed as

$$k_{ij} = k_\xi e_{\xi i} e_{\xi j} + k_\eta e_{\eta i} e_{\eta j} + k_\zeta e_{\zeta i} e_{\zeta j} \tag{8.54}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To define an orthotropic thermal conductivity in solids, select **orthotropic** in the drop-down list for **Thermal Conductivity** in the Create/Edit Materials Dialog Box (p. 4833). This opens the Orthotropic Conductivity Dialog Box (p. 4874) (Figure 8.25: The Orthotropic Conductivity Dialog Box (p. 1625)).

Figure 8.25: The Orthotropic Conductivity Dialog Box



Since the directions $\left(\hat{e}_\xi, \hat{e}_\eta, \hat{e}_\zeta\right)$ are mutually orthogonal, only the first two need to be specified for three-dimensional problems. $\hat{e}_\xi$ is defined using **X, Y, Z** under **Direction 0 Components**, and $\hat{e}_\eta$ is defined using **X, Y, Z** under **Direction 1 Components**. You can define **Conductivity 0** $\left(k_\xi\right)$, **Conductivity 1** $\left(k_\eta\right)$, and **Conductivity 2** $\left(k_\zeta\right)$ as **constant**, **polynomial**, **piecewise-linear**, **piecewise-polynomial** functions of temperature, **user-defined**, **expression**, or as a **New Input Parameter**. See Constant Thermal Conductivity (p. 1619) and Thermal Conductivity as a Function of Temperature (p. 1620) for details on constant and temperature profile functions.

When you select the **user-defined** option, the User-Defined Functions Dialog Box (p. 4863) will open, allowing you to hook a `DEFINE_PROPERTY` UDF *only* if you have previously loaded a compiled UDF library or interpreted the UDF. Otherwise, you will get an error message. More information about user-defined functions can be found in the Fluent Customization Manual.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When you select the **expression** option, the Expression Dialog Box (p. 5405) will open, allowing you to define an expression for each of the conductivity component fields. Refer to Fluent Expressions Language (p. 1013) for more information on defining expressions.

When you select the **New Input Parameter** option, the **Parameter Expression** dialog box will open as described in Defining and Viewing Parameters (p. 1287). Note that to specify an orthotropic conductivity as an input parameter though the TUI, you must first use the command `define/parameters/enable-in-TUI? yes`.

Important:

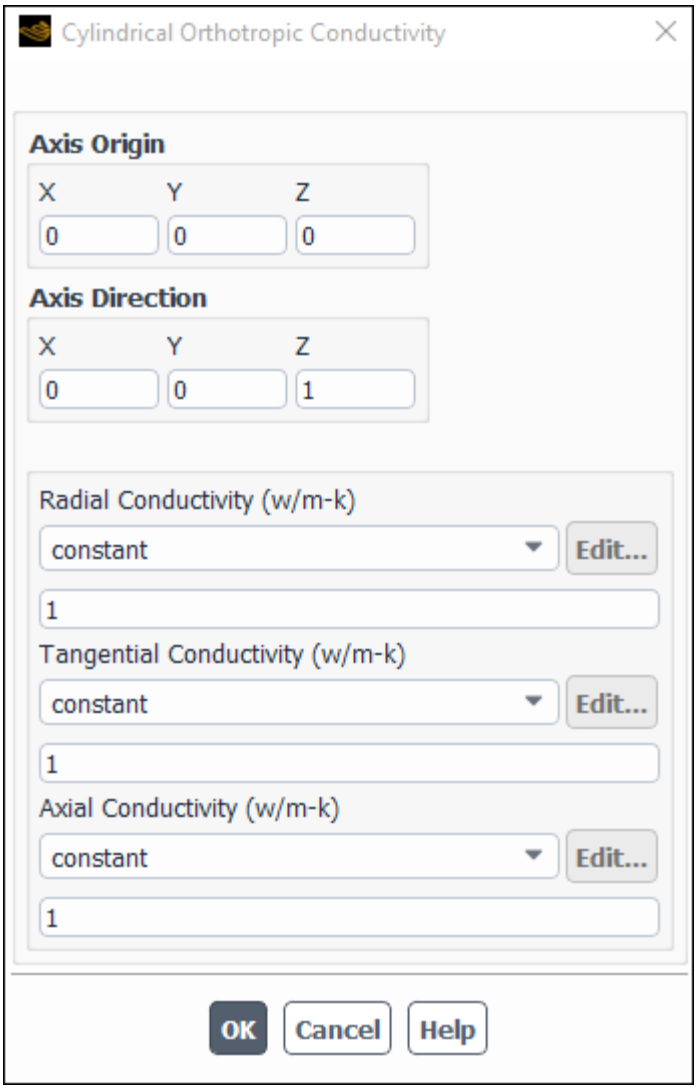
For two-dimensional problems, only the functions $\left(k_\xi, k_\eta\right)$ and the unit vector $\left(\hat{e}_\xi\right)$ need to be specified.

8.5.6.4. Cylindrical Orthotropic Thermal Conductivity

The orthotropic conductivity of solids can be specified in cylindrical coordinates. To define the orthotropic thermal conductivity in cylindrical coordinates, select **cyl-orthotropic** in the drop-down list for **Thermal Conductivity** in the Create/Edit Materials Dialog Box (p. 4833). This opens the Cylindrical Orthotropic Conductivity Dialog Box (p. 4872) (Figure 8.26: The Cylindrical Orthotropic Conductivity Dialog Box (p. 1627)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 8.26: The Cylindrical Orthotropic Conductivity Dialog Box



In three-dimensional cases, the origin and the direction of the cylindrical coordinate system must be specified along with the radial, tangential, and axial direction conductivities. In two-dimensional cases, the origin of the cylindrical coordinate system must be specified along with the radial and tangential direction conductivities. Note that in two-dimensional cases, the direction is always along the +Z axis. Ansys Fluent will automatically compute the anisotropic conductivity matrix at each cell from this input. The calculation is based on the location of the cell in the cylindrical coordinate system specified.

You can define the **Radial Conductivity**, **Tangential Conductivity**, and **Axial Conductivity** as **constant**, **polynomial**, **piecewise-linear**, **piecewise-polynomial**, or as user-defined functions of temperature. See Constant Thermal Conductivity (p. 1619) and Thermal Conductivity as a Function of Temperature (p. 1620) for details on constant and thermal profile functions.

When you select the **user-defined** option, the User-Defined Functions Dialog Box (p. 4863) will open, allowing you to hook a `DEFINE_PROPERTY` UDF *only* if you have previously loaded a compiled

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

UDF library or interpreted the UDF. Otherwise, you will get an error message. More information about user-defined functions can be found in the Fluent Customization Manual.

Important:

For conductivity calculations near the wall, the cell next to the wall is chosen for computing the conductivity matrix instead of the wall itself.

8.5.6.5. Principal Axes and Principal Values

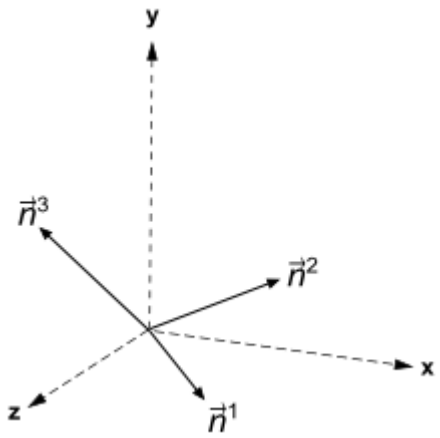
When the principal axes of your anisotropic material are not aligned with the global coordinate system of the simulation, you can define the thermal conductivity using the components of these axes ($\vec{n}^1$, $\vec{n}^2$, and for 3D problems, $\vec{n}^3$) and the associated principle values (K_1, K_2, and for 3D problems, K_3). The axes take the following form:

$$\begin{aligned}\vec{n}^1 &= n_1^1\hat{i} + n_2^1\hat{j} + n_3^1\hat{k} \\ \vec{n}^2 &= n_1^2\hat{i} + n_2^2\hat{j} + n_3^2\hat{k} \\ \vec{n}^3 &= n_1^3\hat{i} + n_2^3\hat{j} + n_3^3\hat{k}\end{aligned} \tag{8.55}$$

Note that while the axes must be linearly independent vectors, they do not have to be unit vectors or orthogonal.

An example of principal axes that are not aligned with the global coordinate system is shown in Figure 8.27: Unaligned Principal Axes (p. 1628).

Figure 8.27: Unaligned Principal Axes



Representing the thermal conductivity matrix (k_{ij} in Equation 8.52 (p. 1622)) in matrix notation ($[\mathbf{k}]$), the following equation is used by Ansys Fluent to transform the principal axes and principal values into the correct tensor form:

$$[\mathbf{k}] = [\mathbf{N}][\mathbf{D}][\mathbf{N}]^{-1} \tag{8.56}$$

The matrices in the previous equation are defined as follows:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

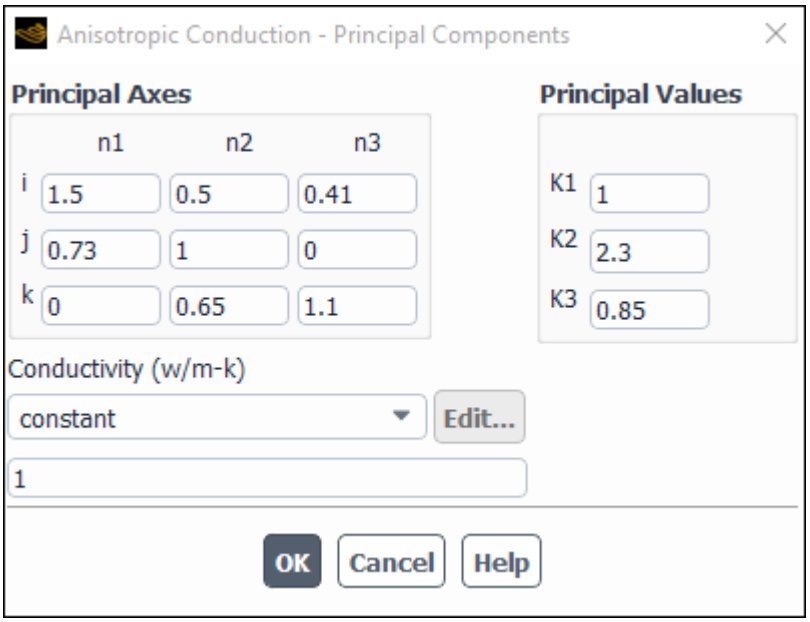
$$[\mathbf{N}] = \begin{bmatrix} n_1^1 & n_1^2 & n_1^3 \\ n_2^1 & n_2^2 & n_2^3 \\ n_3^1 & n_3^2 & n_3^3 \end{bmatrix} \tag{8.57}$$

$$[\mathbf{D}] = \begin{bmatrix} kK_1 & 0 & 0 \\ 0 & kK_2 & 0 \\ 0 & 0 & kK_3 \end{bmatrix} \tag{8.58}$$

where k is the conductivity.

To use principal axes and principal values to define the anisotropic thermal conductivity for your solid material, select **principal-axes-values** for **Thermal Conductivity** in the Create/Edit Materials Dialog Box (p. 4833) (Figure 8.22: The Create/Edit Materials Dialog Box (p. 1619)). This will open the Anisotropic Conduction - Principal Components Dialog Box (p. 4875) (Figure 8.28: The Anisotropic Conductivity - Principal Components Dialog Box (p. 1629)).

Figure 8.28: The Anisotropic Conductivity - Principal Components Dialog Box



In the **Principal Axes** group box of the Anisotropic Conduction - Principal Components Dialog Box (p. 4875), enter the **i**, **j**, and **k** components for each of the **n1**, **n2**, and **n3** vectors (Equation 8.55 (p. 1628)) that define the principal axes of your material in the global coordinate system; note that these must be linearly independent vectors. Then in the **Principal Values** group box, enter the **K1**, **K2**, and **K3** values that define the magnitudes of the principal values along the associated principal axes. Finally, make a selection from the **Conductivity** drop-down menu to specify k (in Equation 8.58 (p. 1629)) as a **constant**, polynomial function of temperature (**polynomial**, **piecewise-linear**, **piecewise-polynomial**), or **user-defined** function, and then define it using the number-entry box that becomes available or the dialog box that opens. See Constant Thermal Conductivity (p. 1619) and Thermal Conductivity as a Function of Temperature (p. 1620) for details on constants and thermal functions.

When you select the **user-defined** option, the User-Defined Functions Dialog Box (p. 4863) will open, allowing you to hook a `DEFINE_PROPERTY` UDF *only* if you have previously loaded a compiled

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

UDF library or interpreted the UDF. Otherwise, you will get an error message. Details about user-defined functions can be found in the Fluent Customization Manual.

8.5.6.6. User-Defined Anisotropic Thermal Conductivity

You have the option of modeling anisotropic conduction for domains where the components of the thermal conductivity matrix (k_{ij} in Equation 8.53 (p. 1623)) are not constants and vary independently, perhaps as a function of space or because the domain has many anisotropic materials stitched together to form a composite. To use this option, you must first define the conductivity matrix using a UDF, as described in `DEFINE_ANISOTROPIC_CONDUCTIVITY` in the Fluent Customization Manual.

After you have interpreted or compiled the `DEFINE_ANISOTROPIC_CONDUCTIVITY` UDF, you must then select **user-defined-anisotropic-k** for **Thermal Conductivity** in the Create/Edit Materials Dialog Box (p. 4833). This will open the User-Defined Functions Dialog Box (p. 4863), which you can use to hook the UDF.

8.6. User-Defined Scalar (UDS) Diffusivity

There are two types of UDS diffusivity that you can specify in Ansys Fluent: isotropic and anisotropic. Diffusion is isotropic when it is the same in all directions. Isotropic diffusion coefficients can be specified in two ways: either as a single **user-defined** that applies to all UDS transport equations defined for your model; or on a per-scalar basis as **constants**, **polynomial** functions of temperature, or **user-defined** functions.

Diffusion is anisotropic when the diffusion coefficients are different in different directions. Anisotropic diffusion can be specified by a tensor diffusion coefficient matrix Γ (Equation 8.59 (p. 1630)) for each UDS (in both fluid and solid zones) in four different ways: general **anisotropic**, **orthotropic**, **cyl-orthotropic**, and **user-defined-anisotropic**. All UDS diffusivity parameters are set from the Create/Edit Materials Dialog Box (p. 4833) and are discussed below. Note that details about how to define and use UDFs in UDS transport equations is discussed in the Fluent Customization Manual.

The second-order diffusion term in the most general form is

$$\nabla \cdot \left(\Gamma \cdot \nabla \phi^k \right) \tag{8.59}$$

where Γ is a 3 × 3 tensor in 3D.

For additional information, see the following sections:

8.6.1. Isotropic Diffusion

8.6.2. Anisotropic Diffusion

8.6.3. User-Defined Anisotropic Diffusivity

8.6.1. Isotropic Diffusion

For isotropic diffusion, Γ in Equation 8.59 (p. 1630) is equal to a scalar Γ times the identity matrix and the equation reduces to

$$\nabla \cdot \left(\Gamma \nabla \phi^k \right) \tag{8.60}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

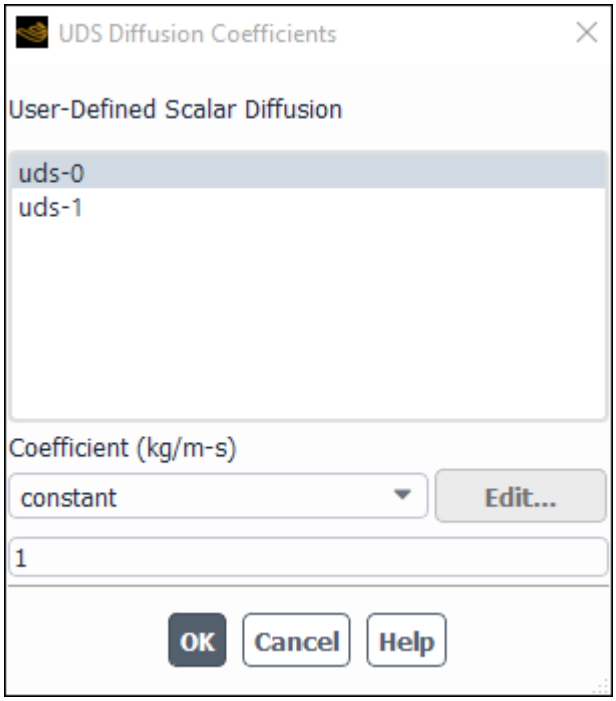
You can specify isotropic diffusivity as a single user-defined function that applies to all UDS transport equations. For this case, choose **user-defined** from the drop-down list for **UDS Diffusivity** in the Create/Edit Materials Dialog Box (p. 4833).

Setup → Materials

If you have previously loaded a compiled UDF library or have interpreted the UDF, then the User-Defined Functions Dialog Box (p. 4863) will open, allowing you to hook the `DEFINE_DIFFUSIVITY` UDF to Ansys Fluent. If no functions have been loaded, you will get an error message. More information about user-defined functions can be found in the Fluent Customization Manual.

Isotropic diffusion coefficients can also be defined on a per-scalar basis by selecting **defined-per-uds** from the drop-down list for **UDS Diffusivity** in the Create/Edit Materials Dialog Box (p. 4833). This will open the UDS Diffusion Coefficients Dialog Box (p. 4894) (Figure 8.29: The UDS Diffusion Coefficients Dialog Box (p. 1631)).

Figure 8.29: The UDS Diffusion Coefficients Dialog Box



In the UDS Diffusion Coefficients Dialog Box (p. 4894), select a scalar equation (for example, **uds-0**) and then choose a **constant**, **polynomial**, or **user-defined** function from the **Coefficient** drop-down list. For the default fluid (air), the constant diffusion coefficient is 1 kg/m-s. If you choose **polynomial**, the Polynomial Profile Dialog Box (p. 4854) will open and you can specify your coefficients as a function of temperature. See Inputs for Polynomial Functions (p. 1591) for details.

When you select the **user-defined** option, the User-Defined Functions Dialog Box (p. 4863) will open, allowing you to hook a `DEFINE_DIFFUSIVITY` UDF *only* if you have previously loaded a compiled UDF library or interpreted a UDF. Otherwise, you will get an error message. More information about user-defined functions can be found in the Fluent Customization Manual.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8.6.2. Anisotropic Diffusion

You can specify anisotropic diffusion coefficients in both fluid and solid zones by defining the tensor diffusion coefficient matrix Γ (Equation 8.59 (p. 1630)) on a per-scalar basis. You can use anisotropic diffusivity for UDS scalar transport equations to model species transport equations in porous media and in solids where species diffusion shows anisotropic behavior.

Important:

- Note that the anisotropic diffusion options discussed in the following sections are available with the pressure-based solver and the density-based solvers.
- UDS diffusion coefficients can be postprocessed only in those cells that have isotropic diffusivity. In all other cells, the diffusion coefficient will be zero.

In all cases, you enable anisotropic diffusion by selecting **defined-per-uds** under **UDS Diffusivity** in the Create/Edit Materials Dialog Box (p. 4833). This will open the UDS Diffusion Coefficients Dialog Box (p. 4894) (Figure 8.29: The UDS Diffusion Coefficients Dialog Box (p. 1631)).

Setup → Materials

In the UDS Diffusion Coefficients Dialog Box (p. 4894), select a scalar equation (for example, **uds-0**) and then choose one of the following methods under **Coefficient** to specify the anisotropic diffusion coefficient. These methods are described in detail below.

- anisotropic
- orthotropic
- cylindrical orthotropic
- user-defined anisotropic

8.6.2.1. Anisotropic Diffusivity

For anisotropic diffusivity, you can specify Γ in Equation 8.59 (p. 1630) in the form $K\mathbf{\Gamma}$ where K is a constant $3x3$ matrix in 3D and Γ is a scalar multiplier.

The diffusion coefficient matrix is specified as

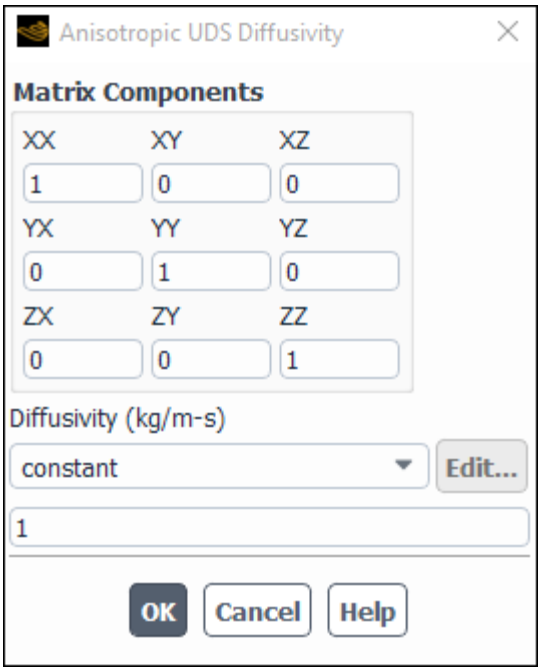
$$k_{ij}=k\hat{e}_{ij} \tag{8.61}$$

where k is the diffusivity and $\hat{e}_{ij}$ is a matrix (2 × 2 for two dimensions and 3 × 3 for three-dimensional problems). Note that $\hat{e}_{ij}$ can be a non-symmetric matrix.

To specify anisotropic diffusion coefficients, first select a scalar equation (for example, **uds-0**) from the **User-Defined Scalar Diffusion** list in the UDS Diffusion Coefficients Dialog Box (p. 4894) (Figure 8.29: The UDS Diffusion Coefficients Dialog Box (p. 1631)). Then choose **anisotropic** in the drop-down list under **Coefficient**. This will open the **Anisotropic UDS Diffusivity** dialog box (Figure 8.30: The Anisotropic UDS Diffusivity Dialog Box (p. 1633)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 8.30: The Anisotropic UDS Diffusivity Dialog Box



In the **Anisotropic UDS Diffusivity** dialog box, enter the **Matrix Components** and then select the **Diffusivity** to be a **constant**, polynomial function of temperature (**polynomial**, **piecewise-linear**, **piecewise-polynomial**), or **user-defined**. See Inputs for Polynomial Functions (p. 1591), Inputs for Piecewise-Linear Functions (p. 1592), and Inputs for Piecewise-Polynomial Functions (p. 1594) for details on polynomial temperature functions.

When you select the **user-defined** option, the User-Defined Functions Dialog Box (p. 4863) will open, allowing you to hook a `DEFINE_DIFFUSIVITY` UDF *only* if you have previously loaded a compiled UDF library or interpreted a UDF. Otherwise, you will get an error message. More information about user-defined functions can be found in the Fluent Customization Manual.

8.6.2.2. Orthotropic Diffusivity

For orthotropic diffusivity, you can specify Γ in Equation 8.59 (p. 1630) through 'principal' direction vectors and diffusion coefficients along these directions. Ansys Fluent, in turn, computes Γ from parameters that you supply. The principal directions are the same everywhere, but each of he directional diffusion coefficients can be specified as a constant, polynomial function of temperature, or through user-defined functions.

When orthotropic diffusivity is used, the diffusion coefficients $\left(k_\xi, k_\eta, k_\zeta\right)$ in the principal directions $\left(\hat{e}_\xi, \hat{e}_\eta, \hat{e}_\zeta\right)$ are specified. The diffusivity matrix is then computed as

$$k_{ij} = k_\xi e_{\xi i} e_{\xi j} + k_\eta e_{\eta i} e_{\eta j} + k_\zeta e_{\zeta i} e_{\zeta j} \tag{8.62}$$

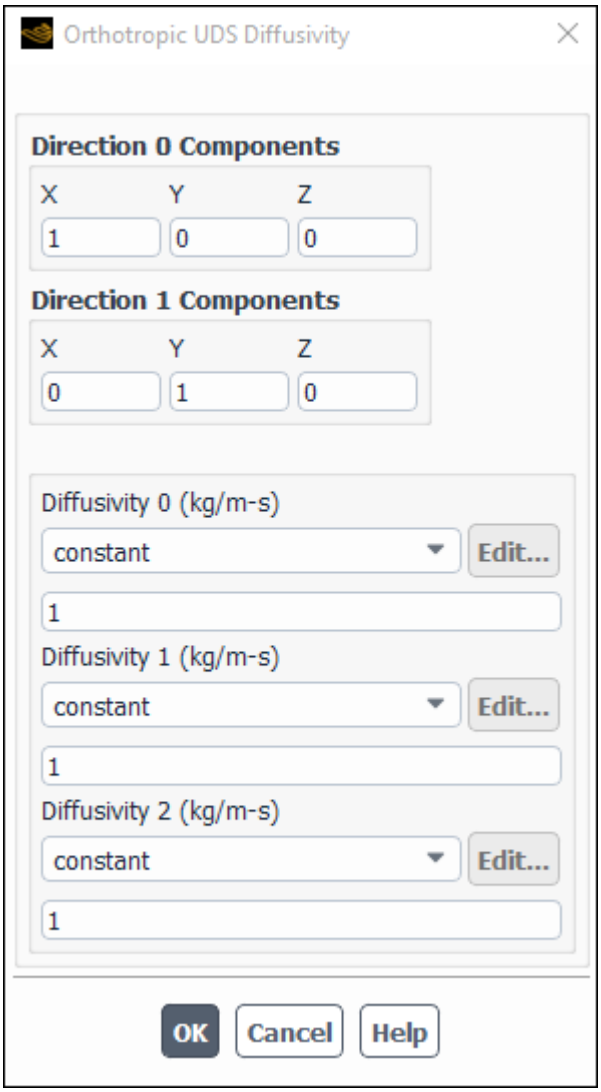
Important:

For two-dimensional problems, only the functions $\left(k_\xi, k_\eta\right)$ and the unit vector $\left(\hat{e}_\xi\right)$ need to be specified.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To specify orthotropic diffusion coefficients, first select a scalar equation (for example, **uds-0**) from the **User-Defined Scalar Diffusion** list in the UDS Diffusion Coefficients Dialog Box (p. 4894) (Figure 8.29: The UDS Diffusion Coefficients Dialog Box (p. 1631)). Then choose **orthotropic** in the drop-down list under **Coefficient**. This will open the **Orthotropic UDS Diffusivity** dialog box (Figure 8.31: The Orthotropic UDS Diffusivity Dialog Box (p. 1634)).

Figure 8.31: The Orthotropic UDS Diffusivity Dialog Box



Since the directions $\left(\hat{e}_\xi, \hat{e}_\eta, \hat{e}_\zeta\right)$ are mutually orthogonal, only the first two need to be specified for three-dimensional problems. $\hat{e}_\xi$ is defined using **X,Y,Z** under **Direction 0 Components**, and $\hat{e}_\eta$ is defined using **X,Y,Z** under **Direction 1 Components**. You can define **Diffusivity 0** $\left(k_\xi\right)$, **Diffusivity 1** $\left(k_\eta\right)$, and **Diffusivity 2** $\left(k_\zeta\right)$ as **constant**, **polynomial**, **piecewise-linear**, **piecewise-polynomial** functions of temperature, or **user-defined**. See Inputs for Polynomial Functions (p. 1591), Inputs for Piecewise-Linear Functions (p. 1592), and Inputs for Piecewise-Polynomial Functions (p. 1594) for details on polynomial temperature functions.

When you select the **user-defined** option, the User-Defined Functions Dialog Box (p. 4863) will open, allowing you to hook a `DEFINE_DIFFUSIVITY` UDF *only* if you have previously loaded a compiled

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

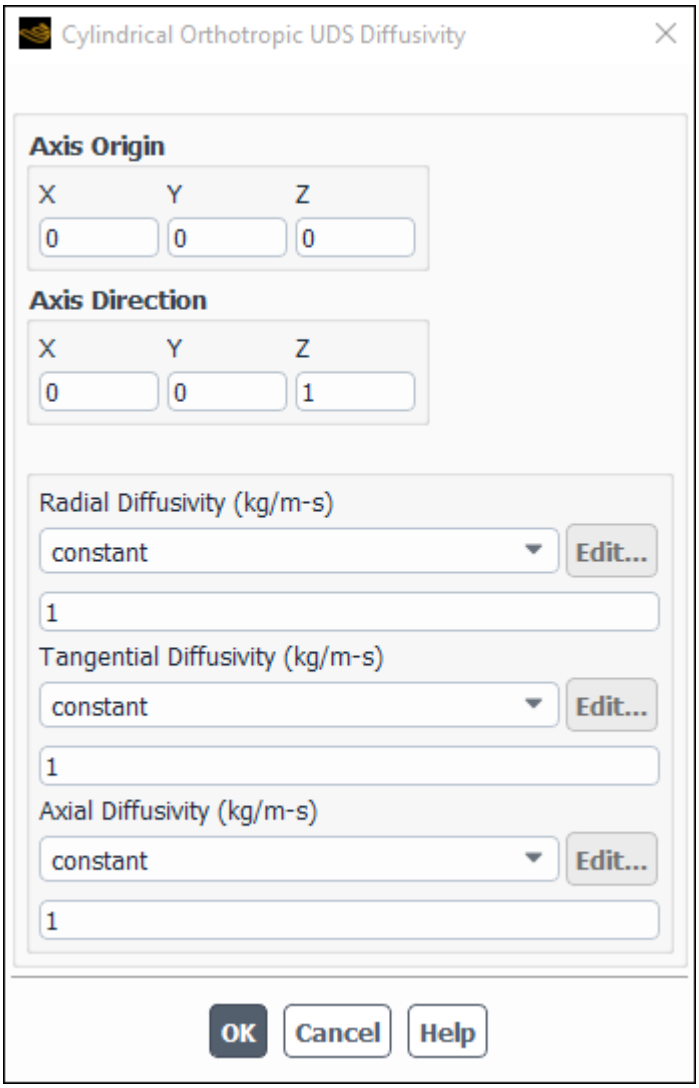
UDF library or interpreted a UDF. If no functions have been loaded, you will get an error message. More information about user-defined functions can be found in the Fluent Customization Manual.

8.6.2.3. Cylindrical Orthotropic Diffusivity

Orthotropic UDS diffusivity can also be specified on a per-scalar basis in cylindrical coordinates. This method is similar to orthotropic UDS diffusivity, except that the principal directions are specified as radial, tangential, and axial.

To specify cylindrical orthotropic diffusion coefficients, first select a scalar equation (for example, **uds-0**) from the **User-Defined Scalar Diffusion** list in the UDS Diffusion Coefficients Dialog Box (p. 4894) (Figure 8.29: The UDS Diffusion Coefficients Dialog Box (p. 1631)). Then choose **cyl-orthotropic** in the drop-down list under **Coefficient**. This will open the **Cylindrical Orthotropic UDS Diffusivity** dialog box (Figure 8.32: The Cylindrical Orthotropic UDS Diffusivity Dialog Box (p. 1635)).

Figure 8.32: The Cylindrical Orthotropic UDS Diffusivity Dialog Box



In three-dimensional cases, the origin and the direction of the cylindrical coordinate system must be specified along with the radial, tangential, and axial direction conductivities. In two-dimensional cases, the origin of the cylindrical coordinate system must be specified along with the radial and

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

tangential direction conductivities. Note that in two-dimensional cases, the direction is always along the +z axis. Ansys Fluent will automatically compute the anisotropic diffusivity matrix at each cell from this input. The calculation is based on the location of the cell in the cylindrical coordinate system specified.

You can define the **Radial Diffusivity**, **Tangential Diffusivity**, and **Axial Diffusivity** as **constant**, **polynomial**, **piecewise-linear**, **piecewise-polynomial**, or as **user-defined** functions of temperature, using the drop-down list below each of the diffusivities. See Inputs for Polynomial Functions (p. 1591), Inputs for Piecewise-Linear Functions (p. 1592), and Inputs for Piecewise-Polynomial Functions (p. 1594) for details on polynomial temperature functions.

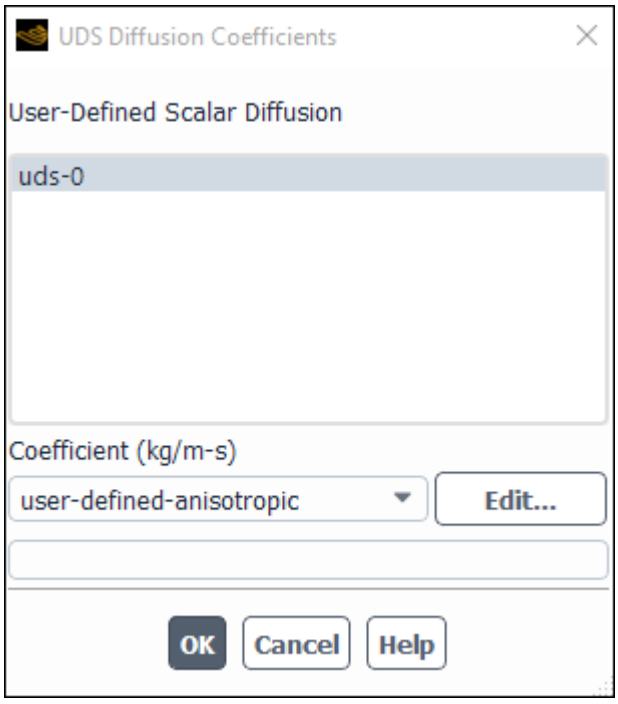
When you select the **user-defined** option, the User-Defined Functions Dialog Box (p. 4863) will open, allowing you to hook a `DEFINE_DIFFUSIVITY` UDF *only* if you have previously loaded a compiled UDF library or interpreted a UDF. If no functions have been loaded, you will get an error message. More information about user-defined functions can be found in the Fluent Customization Manual.

8.6.3. User-Defined Anisotropic Diffusivity

You can specify Γ in Equation 8.59 (p. 1630) on a per-scalar basis, directly, through user-defined functions (UDFs).

To specify a UDF for anisotropic diffusivity on a per-scalar basis, first select a scalar equation (for example, **uds-0**) from the **User-Defined Scalar Diffusion** list in the UDS Diffusion Coefficients Dialog Box (p. 4894) (Figure 8.33: The UDS Diffusion Coefficients Dialog Box (p. 1636)).

Figure 8.33: The UDS Diffusion Coefficients Dialog Box



Then choose **user-defined-anisotropic** in the drop-down list under **Coefficient**. The User-Defined Functions Dialog Box (p. 4863) will open, allowing you to hook a `DEFINE_ANISOTROPIC_DIFFUSIVITY` UDF *only* if you have previously loaded a compiled UDF library or interpreted a UDF. Otherwise,

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

you will get an error message. More information about user-defined functions can be found in the Fluent Customization Manual.

8.7. Specific Heat Capacity

The specific heat capacity must be defined when the energy equation is active. Ansys Fluent provides several options for definition of the heat capacity:

- constant heat capacity
- temperature- and/or composition-dependent heat capacity
- kinetic theory

Each of these input options and the governing physical models are detailed in this section. In all cases, you will define the **Cp** in the Create/Edit Materials Dialog Box (p. 4833).

Setup → **Materials**

Specific heat capacity is input in units of J/kg-K in SI units or BTU/lbm-°R in British units.

Important:

For combustion applications, a temperature-dependent specific heat is recommended.

For additional information, see the following sections:

8.7.1. Input of Constant Specific Heat Capacity
8.7.2. Specific Heat Capacity as a Function of Temperature
8.7.3. Defining Specific Heat Capacity Using Kinetic Theory
8.7.4. Specific Heat Capacity as a Function of Composition

8.7.1. Input of Constant Specific Heat Capacity

If you want to define the heat capacity as a constant, check that **constant** is selected in the drop-down list to the right of **Cp** in the Create/Edit Materials Dialog Box (p. 4833), and enter the value of heat capacity.

The specific heat for the default fluid (air) is 1006.43 J/kg-K.

8.7.2. Specific Heat Capacity as a Function of Temperature

You can also choose to define the specific heat capacity as a function of temperature. Three types of functions are available:

- piecewise-linear:

$$c_p(T) = c_{p_n} + \frac{c_{p_{n+1}} - c_{p_n}}{T_{n+1} - T_n}(T - T_n) \tag{8.63}$$

- piecewise-polynomial:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\text{for } T_{min,1} \le T < T_{max,1}: c_p(T) = A_1 + A_2 T + A_3 T^2 + \ldots$$
$$\text{for } T_{min,2} \le T < T_{max,2}: c_p(T) = B_1 + B_2 T + B_3 T^2 + \ldots \tag{8.64}$$

- nasa-9-piecewise-polynomial:

$$\text{for} \quad T_{min,1} \le T < T_{max,1}: Cp(T) = A_1 T^{-2} + A_2 T^{-1} + A_3 + A_4 T + A_5 T^2 + A_6 T^3 + A_7 T^4$$
$$\text{for} \quad T_{min,2} \le T < T_{max,2}: Cp(T) = B_1 T^{-2} + B_2 T^{-1} + B_3 + B_4 T + B_5 T^2 + B_6 T^3 + B_7 T^4 \tag{8.65}$$

- polynomial:

$$c_p(T) = A_1 + A_2 T + A_3 T^2 + \ldots \tag{8.66}$$

You can input the data pairs (T_n,c_{p_n}), ranges and coefficients A_i and B_i, or coefficients A_i that describe these functions using the Create/Edit Materials Dialog Box (p. 4833), as described in Defining Properties Using Temperature-Dependent Functions (p. 1590).

8.7.3. Defining Specific Heat Capacity Using Kinetic Theory

If you are using the ideal gas law (as described in Density (p. 1598)), you have the option to define the specific heat capacity using kinetic theory as

$$c_{p,i} = \frac{1}{2}\frac{R}{M_{w,i}}\left(f_i + 2\right) \tag{8.67}$$

where f_i is the number of modes of energy storage (degrees of freedom) for the gas species i that you can input by selecting **kinetic-theory** from the drop-down list to the right of **Cp** in the Create/Edit Materials Dialog Box (p. 4833). The solver will use your kinetic theory inputs in Equation 8.67 (p. 1638) to compute the specific heat capacity. See Kinetic Theory Parameters (p. 1650) for details about kinetic theory inputs.

8.7.4. Specific Heat Capacity as a Function of Composition

If you are modeling a flow that includes more than one chemical species (multicomponent flow), you have the option to define a composition-dependent specific heat capacity. You can also define the heat capacity of the mixture as a constant value or a function of temperature, or using kinetic theory.

To define a composition-dependent specific heat capacity for a mixture, follow these steps:

1. For the mixture material, choose **mixing-law** in the drop-down list to the right of **Cp**.
2. Click **Change/Create**.
3. Define the specific heat capacity for each of the fluid materials that make up the mixture. You may define constant or (if applicable) temperature-dependent heat capacities for the individual species. You may also use kinetic theory for the individual heat capacities, if applicable.

The solver will compute the mixture's specific heat capacity as a mass fraction average of the pure species heat capacities:

$$c_p = \sum_i Y_i c_{p,i} \tag{8.68}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8.8. Radiation Properties

When you have activated one of the radiation models (except for the surface-to-surface model, which requires no additional properties), there will be additional properties for you to set in the Create/Edit Materials Dialog Box (p. 4833):

- For the P-1 model, you must set the radiation **Absorption Coefficient** and **Scattering Coefficient** (a and σ_s in Equation 5.57 in the Theory Guide).
- For the Rosseland model, set the **Absorption Coefficient** and **Scattering Coefficient** (a and σ_s in Equation 5.58 in the Theory Guide).
- For the DTRM, only the **Absorption Coefficient** is required (a in Equation 5.91 in the Theory Guide).
- For the DO model, set the **Absorption Coefficient** and the **Scattering Coefficient** (a and σ_s in Equation 5.98 in the Theory Guide). In addition, if you are modeling semi-transparent media, specify the **Refractive Index** (n_a or n_b in Equation 5.117 in the Theory Guide). With the DO model, you can specify radiation properties for solid materials, to be used when semi-transparent media are modeled.
- For the MC model, set the **Absorption Coefficient** and the **Scattering Coefficient** (a and σ_s in Equation 5.98 in the Theory Guide). In addition, if you are modeling semi-transparent media, specify the **Refractive Index** (n_a or n_b in Equation 5.117 in the Theory Guide). With the MC model, you can specify radiation properties for solid materials, to be used when semi-transparent media are modeled.

For additional information, see the following sections:

8.8.1. Absorption Coefficient

8.8.2. Scattering Coefficient

8.8.3. Refractive Index

8.8.4. Reporting the Radiation Properties

8.8.1. Absorption Coefficient

To define the absorption coefficient, you can specify a constant value, a temperature-dependent function (see Defining Properties Using Temperature-Dependent Functions (p. 1590)), a composition-dependent function, or a user-defined function. The absorbing and emitting parts of the radiative transfer equation (RTE), Equation 5.56 in the Theory Guide, is a function of the absorption coefficient. The absorbing or emitting effects depend on the chosen radiation model. If there are only absorption effects, then Lambert's Law of absorption applies

$$I = I_o \exp\left(-ax\right) \tag{8.69}$$

where I is the radiation intensity, a is the absorption coefficient, and x is the distance through the material.

If you are modeling non-gray radiation with the P-1, DO, or MC radiation models, you also have the option to specify a constant absorption coefficient in each of the gray bands. The absorption coefficient is requested in units of 1/length. Along with the scattering coefficient, it describes the change in radiation intensity per unit length along the path through the fluid medium. Absorption coefficients can be computed using tables of emissivity for CO_2 and H_2O, which are generally available in textbooks on radiation heat transfer.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8.8.1.1. Inputs for a Constant Absorption Coefficient

To define a constant absorption coefficient, simply enter the value in the field next to **Absorption Coefficient** in the Create/Edit Materials Dialog Box (p. 4833). Select **constant** in the drop-down list first if it is not already selected.

8.8.1.2. Inputs for a Composition-Dependent Absorption Coefficient

Ansys Fluent also allows you to input a composition-dependent absorption coefficient, where the local value of a is a function of the local mass fractions of water vapor and carbon dioxide. This modeling option can be useful for the simulation of radiation in combustion applications. The variable-absorption-coefficient model used by Ansys Fluent is the weighted-sum-of-gray-gases model (WSGGM) described in Radiation in Combusting Flows in the Theory Guide. To activate it, first enable the species calculation and make sure that CO_2 and H_2O are present in the mixture. Next, select **wsggm-domain-based**, **wsggm-user-specified**, or **user-defined-wsggm** in the drop-down list to the right of **Absorption Coefficient** in the **Create/Edit Materials** dialog box. If you select **user-defined-wsggm**, the **User-Defined Functions** dialog box will open, allowing you to select a previously loaded compiled UDF library or a previously interpreted UDF (see Hooking `DEFINE_WSGGM_ABS_COEFF` UDFs in the Fluent Customization Manual). The WSGGM options differ in the method used to compute the path length, as described in the section that follows.

8.8.1.2.1. Path Length Inputs

When the WSGGM is used to compute the absorption coefficient, you can choose how path length, s, is defined for Equation 5.145 in the Theory Guide. See Radiation in Combusting Flows in the Theory Guide to determine which method is appropriate for your case.

You will select the path length method when you choose the property input method for **Absorption Coefficient**, as described previously.

- If you choose **wsggm-domain-based**, s is set equal to a mean beam length calculated by Ansys Fluent according to Equation 5.146 in the Theory Guide, which is an average dimension of the domain; no further inputs are required.
- If you choose **wsggm-user-specified**, s is set equal to a mean beam length that you enter for **Path Length** in the WSGGM User Specified Dialog Box (p. 4895).
- If you choose **user-defined-wsggm**, Ansys Fluent will initially compute the absorption coefficient in the same manner as described for the **wsggm-domain-based** option; however, you have the option of writing a user-defined function that customizes this calculated value. If the soot model is enabled, you can also use the UDF to customize the soot absorption coefficient computed by Ansys Fluent. See `DEFINE_WSGGM_ABS_COEFF` in the Fluent Customization Manual for further details.

8.8.1.2.1.1. Inputs for a Non-Gray Radiation Absorption Coefficient

If you are using the non-gray DO model (see The DO Model Equations of the Theory Guide and Defining Non-Gray Radiation for the DO Model (p. 2176)), the non-gray P-1 model (see The P-1 Model Equations of the Theory Guide and Setting Up the P-1 Model with Non-Gray Radiation (p. 2158)), or the non-gray MC model (see Monte Carlo (MC) Radiation Model Theory), you can specify a different constant absorption coefficient for each of the bands used by the gray-band model. Select **gray-band** from the **Absorption Coefficient** drop-down list in the **Cre-**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ate/Edit Materials dialog box and then define the absorption coefficient for each band in the Gray-Band Absorption Coefficient Dialog Box (p. 4896). (Note that you must complete this dialog box in order to proceed.)

8.8.1.2.1.2. Effect of Particles and Soot on the Absorption Coefficient

Ansys Fluent will include the effect of particles on the absorption coefficient if you have turned on the **Particle Radiation Interaction** option in the Discrete Phase Model Dialog Box (p. 4793) (only for the P-1 and DO radiation models).

If you are modeling soot formation and you want to include the effect of soot formation on the absorption coefficient, turn on the **Soot-Radiation Interaction** in the Soot Model Dialog Box (p. 4773). The soot effects can be included for any of the radiation models, as long as you are using the WSGGM to compute a composition-dependent absorption coefficient. Note that you can use the **user-defined-wsggm** option to customize the soot absorption coefficient calculated by Ansys Fluent, as described previously.

8.8.2. Scattering Coefficient

The scattering coefficient is, by default, set to zero, and it is assumed to be isotropic. You can specify a constant value, a temperature-dependent function (see Defining Properties Using Temperature-Dependent Functions (p. 1590)), or a user-defined function. You can also specify a non-isotropic phase function.

The scattering coefficient is requested in units of 1/length. Along with the absorption coefficient, it describes the change in radiation intensity per unit length along the path through the fluid medium. You may want to increase the scattering coefficient in combustion systems, where particulates may be present.

8.8.2.1. Inputs for a Constant Scattering Coefficient

To define a constant scattering coefficient, simply enter the value in the field next to **Scattering Coefficient** in the Create/Edit Materials Dialog Box (p. 4833). (Select **constant** in the drop-down list first if it is not already selected.)

8.8.2.2. Inputs for the Scattering Phase Function

Scattering is assumed to be isotropic, by default, but you can also specify a linear-anisotropic scattering function. If you are using the DO model, Delta-Eddington and user-defined scattering functions are also available.

8.8.2.2.1. Isotropic Phase Function

To model isotropic scattering, select **isotropic** in the **Scattering Phase Function** drop-down list. No further inputs are necessary. This is the default setting in Ansys Fluent.

8.8.2.2.2. Linear-Anisotropic Phase Function

To model anisotropic scattering, select **linear-anisotropic** in the **Scattering Phase Function** drop-down list and set the value of the phase function coefficient (C in Equation 5.58 in the Theory Guide).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8.8.2.2.3. Delta-Eddington Phase Function

To use a Delta-Eddington phase function, select **delta-eddington** in the **Scattering Phase Function** drop-down list. This will open the Delta-Eddington Scattering Function Dialog Box (p. 4897), in which you can specify the **Forward Scattering Factor** and **Asymmetry Factor** (f and C in Equation 5.107 in the Theory Guide). Since this is a modal dialog box, you must tend to it immediately.

8.8.2.2.4. User-Defined Phase Function

To use a user-defined phase function, select **user-defined** in the **Scattering Phase Function** drop-down list. The user-defined function will contain specifications for Φ^* and f in Equation 5.108 in the Theory Guide. More information about user-defined functions can be found in the Fluent Customization Manual.

8.8.3. Refractive Index

The refractive index is the ratio of speed of light in the medium to the speed of light in vacuum. It is by default set to 1. You can specify a constant value in the field next to **Refractive Index**.

If you are using the non-gray DO model (see The DO Model Equations of the Theory Guide and Defining Non-Gray Radiation for the DO Model (p. 2176)), the non-gray P-1 model (see The P-1 Model Equations of the Theory Guide and Setting Up the P-1 Model with Non-Gray Radiation (p. 2158)), or the non-gray MC model (see Monte Carlo (MC) Radiation Model Theory), you can specify a different constant refractive index for each of the bands used by the gray-band model. Select **refractive-band** from the **Refractive Index** drop-down list in the **Create/Edit Materials** dialog box and then define the refractive index for each band in the Gray-Band Refractive Index Dialog Box (p. 4897). Note that because this is a modal dialog box, you must tend to it immediately.

8.8.4. Reporting the Radiation Properties

You can display the computed local values for a and σ_s using the **Absorption Coefficient** and **Scattering Coefficient** items in the **Radiation...** category of the variable selection drop-down list that appears in postprocessing dialog boxes. You will also find the **Refractive Index** in the **Radiation...** category.

8.9. Mass Diffusion Coefficients

For species transport calculations, you can model the diffusion of chemical species using the following methods:

- Fickian diffusion (default)

  The Fick's law approximation is adequate for most applications. See Mass Diffusion in Laminar Flows and Mass Diffusion in Turbulent Flows in the *Fluent Theory Guide* for more information about the theoretical background of the mass diffusion due to concentration gradients.

- Full multicomponent diffusion

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For some applications (for example, diffusion-dominated laminar flows such as chemical vapor deposition), the full multicomponent diffusion model is recommended. See Full Multicomponent Diffusion in the *Fluent Theory Guide* for more information about the theoretical background of the full multicomponent diffusion.

Important:

The full multicomponent diffusion model is enabled by selecting the **Full Multicomponent Diffusion** option in the Species Model Dialog Box (p. 4716) and is computationally expensive.

By default, the solver computes the species diffusion using:

- For laminar flows: Equation 7.2 in the *Fluent Theory Guide*
- For turbulent flows: Equation 7.4 in the *Fluent Theory Guide*

If you have enabled the **Full Multicomponent Diffusion** option in the Species Model Dialog Box (p. 4716), then the solver computes the diffusive mass flux using Equation 7.8 in the *Fluent Theory Guide*.

The inputs for the diffusion coefficient for species i in the mixture ($D_{i,m}$ in Equation 7.3 in the *Fluent Theory Guide*) or for the individual binary mass diffusion coefficients ($\mathcal{D}_{ij}$ in Equation 7.3 or Equation 7.6 in the *Fluent Theory Guide*) are described in Mass Diffusion Coefficient Inputs (p. 1643).

8.9.1. Mass Diffusion Coefficient Inputs

To specify the mass diffusion coefficients for the mixture, follow the steps below. The diffusion coefficients have units of m^2/s in SI units or ft^2/s in British units.

1. If you are modeling full multicomponent species transport described in Full Multicomponent Diffusion in the *Fluent Theory Guide*, enable the **Full Multicomponent Diffusion** option in the Species Model Dialog Box (p. 4716).
2. If you want to account for thermal diffusion, enable the **Thermal Diffusion** option in the **Species Model dialog** box.
3. Open the **Create/Edit Materials** dialog box for the mixture material.

   Setup → **Materials**
4. In the **Properties** group box, select the specification method for the mass diffusion coefficients from the **Mass Diffusivity** drop-down list. The following options are available:

   - **constant-dilute-appx**: Allows you to specify a constant value for all $D_{i,m}$ in the field below. Ansys Fluent automatically uses the Fickian diffusion (Mass Diffusion in Laminar Flows and Mass Diffusion in Turbulent Flows in the *Fluent Theory Guide*). This method is not available for the **Full Multicomponent Diffusion** option.

     See Constant Dilute Approximation Inputs (p. 1645).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **dilute-approx**: Allows you to define each $D_{i,m}$ as a constant or as a polynomial function of temperature (if heat transfer is enabled). Ansys Fluent automatically uses the Fickian diffusion (Mass Diffusion in Laminar Flows and Mass Diffusion in Turbulent Flows in the *Fluent Theory Guide*). This method is not available for the **Full Multicomponent Diffusion** option.

  See Dilute Approximation Inputs (p. 1645) for details.

- **unity-lewis-number**: No additional inputs are required. The mass diffusion coefficients $D_{i,m}$ are calculated under the assumption of unity Lewis number for all species in the mixture. This method is not available for the **Full Multicomponent Diffusion** option.

  The Lewis number is the ratio of thermal diffusivity (Prandtl number) to mass diffusivity (Schmidt number). The **unity-lewis-number** option is a reasonable approximation when flow is highly turbulent and the contribution of laminar diffusion is small.

- **kinetic-theory**: The solver uses kinetic theory to calculate the binary diffusion of species i in each species j, $\mathcal{D}_{ij}$.

  See Multicomponent Method Inputs (p. 1646) for details.

  For the theory behind this method, see Kinetic Theory Parameters for Diffusion Coefficients in the *Fluent Theory Guide*.

- **multicomponent**: Allows you to define the binary diffusion of species i in each species j, $\mathcal{D}_{ij}$ as a constant or a polynomial function of temperature.

  See Multicomponent Method Inputs (p. 1646) for details.

- **user-defined**: Allows you to define a single user-defined function that applies to all mass diffusion coefficients. This is done using the `DEFINE_DIFFUSIVITY` macro and is explained in the Fluent Customization Manual.

If you are modeling a dilute mixture where the mass fraction of all species is small compared to one dominant species, choose either the **constant-dilute-appx** or **dilute-approx** method to specify $D_{i,m}$. If you are modeling a non-dilute mixture, you may define the individual binary mass diffusion coefficients $\mathcal{D}_{ij}$. The solver will compute the diffusion of species i in the mixture using Equation 7.3 in the *Fluent Theory Guide*, unless you have enabled **Full Multicomponent Diffusion** the **Species Model** dialog box.. In the latter case, the solver will use the inputs for the individual binary mass diffusion coefficients $\mathcal{D}_{ij}$ to calculate the diffusive mass flux according to Equation 7.8 in the *Fluent Theory Guide*.

5. (turbulent flows only) Optionally, you can adjust the **Turbulent Schmidt Number** in the Viscous Model Dialog Box (p. 4663) (**Model Constants** group box). See Mass Diffusion Coefficient Inputs for Turbulent Flow (p. 1647) for more information.

6. If you have enable the **Thermal Diffusion** option in the **Species Model dialog** box, define the thermal diffusion coefficients as described in Thermal Diffusion Coefficient Inputs (p. 1648).

7. If you are modeling anisotropic species diffusion in porous media, configure appropriate settings as described in Anisotropic Species Diffusion (p. 1647).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8.9.1.1. Constant Dilute Approximation Inputs

To use the constant dilute approximation method, follow these steps:

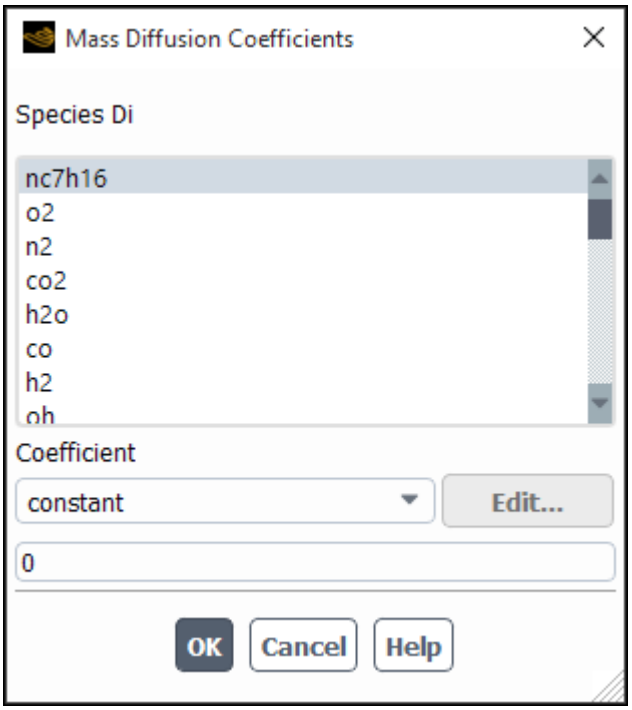
1. Select **constant-dilute-appx** in the drop-down list to the right of **Mass Diffusivity**.
2. Enter a single value of $D_{i,m}$. The same value will be used for the diffusion coefficient of each species in the mixture.

8.9.1.2. Dilute Approximation Inputs

To use the dilute approximation method, follow the steps below:

1. Select **dilute-approx** in the drop-down list to the right of **Mass Diffusivity**.
2. In the resulting Mass Diffusion Coefficients Dialog Box (p. 4892) (Figure 8.34: The Mass Diffusion Coefficients Dialog Box for Dilute Approximation (p. 1645)), select the species in the **Species Di** list for which you are going to define the mass diffusion coefficient.

   Figure 8.34: The Mass Diffusion Coefficients Dialog Box for Dilute Approximation



3. You can define $D_{i,m}$ for the selected species either as a constant value or (if heat transfer is active) as a polynomial function of temperature:
   - To define a constant diffusion coefficient, select **constant** (the default) in the drop-down list below **Coefficient**, and then enter the value in the field below the list.
   - To define a temperature-dependent diffusion coefficient, choose **polynomial** in the **Coefficient** drop-down list and then define the polynomial coefficients as described in Inputs for Polynomial Functions (p. 1591).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$D_{i,m}=A_1+A_2T+A_3T^2+\ldots \tag{8.70}$$

4. Repeat steps 2 and 3 until you have defined diffusion coefficients for all species in the **Species Di** list in the Mass Diffusion Coefficients Dialog Box (p. 4892).

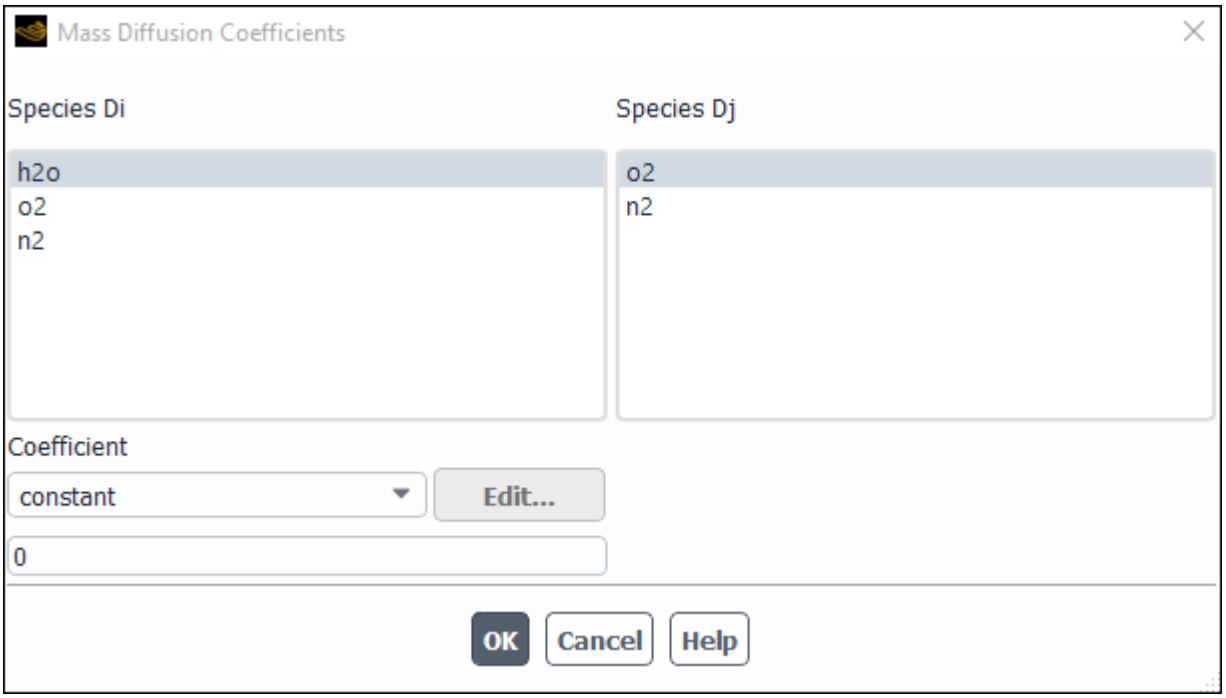
8.9.1.3. Multicomponent Method Inputs

To use the multicomponent method, and define constant or temperature-dependent diffusion coefficients, follow the steps below:

1. Select **multicomponent** in the drop-down list to the right of **Mass Diffusivity**.

2. In the resulting Mass Diffusion Coefficients Dialog Box (p. 4892) (Figure 8.35: The Mass Diffusion Coefficients Dialog Box for the Multicomponent Method (p. 1646)), select the species in the **Species Di** list and the **Species Dj** list for which you are going to define the mass diffusion coefficient D_{ij} for species i in species j.

Figure 8.35: The Mass Diffusion Coefficients Dialog Box for the Multicomponent Method



3. Define $\mathcal{D}_{ij}$ for the selected pair of species using one of the following methods: as a constant value or as a polynomial function of temperature (if heat transfer is active).

   - To define a constant diffusion coefficient, select **constant** (the default) from the**Coefficient** drop-down list, and then enter the value in the field below the list.

   - (only if heat transfer is enabled) To define a temperature-dependent diffusion coefficient, choose **polynomial** in the **Coefficient** drop-down list and then define the polynomial coefficients as described in Inputs for Polynomial Functions (p. 1591).

$$\mathcal{D}_{ij}=A_1+A_2T+A_3T^2+\ldots \tag{8.71}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Repeat steps 2 and 3 until you have defined diffusion coefficients for all pairs of species in the **Species Di** and **Species Dj** lists in the Mass Diffusion Coefficients Dialog Box (p. 4892).

To use the multicomponent method, and define the diffusion coefficient using kinetic theory (available only when the ideal gas law is used), follow these steps:

1. Choose **kinetic-theory** in the drop-down list to the right of **Mass Diffusivity**.
2. Click **Change/Create** after completing other property definitions for the mixture material.
3. Define the Lennard-Jones parameters, σ_i and $\left(\varepsilon / k_B\right)_i$, for each species (fluid material), as described in Kinetic Theory Parameters (p. 1650).

8.9.2. Mass Diffusion Coefficient Inputs for Turbulent Flow

When your flow is turbulent, you will define $D_{i,m}$ or $\mathcal{D}_{ij}$, as described for laminar flows in Mass Diffusion Coefficient Inputs (p. 1643), and you will also have the option to alter the default setting for the turbulent Schmidt number, Sc_t, as defined in Equation 7.5 in the *Fluent Theory Guide*.

Usually, in a turbulent flow, the mass diffusion is dominated by the turbulent transport as determined by the turbulent Schmidt number (Equation 7.5 in the *Fluent Theory Guide*). The turbulent Schmidt number measures the relative diffusion of momentum and mass due to turbulence and is on the order of unity in all turbulent flows. Because the turbulent Schmidt number is an empirical constant that is relatively insensitive to the molecular fluid properties, you will have little reason to alter the default value (0.7) for any species.

Should you want to modify the Schmidt number, enter a new value for **Turbulent Schmidt Number** in the Viscous Model Dialog Box (p. 4663) (**Model Constants** group box).

Setup → Models → Viscous → Edit...

Important:

Note that the full multicomponent diffusion model described in Full Multicomponent Diffusion in the *Fluent Theory Guide* is not recommended for turbulent flows.

8.9.3. Anisotropic Species Diffusion

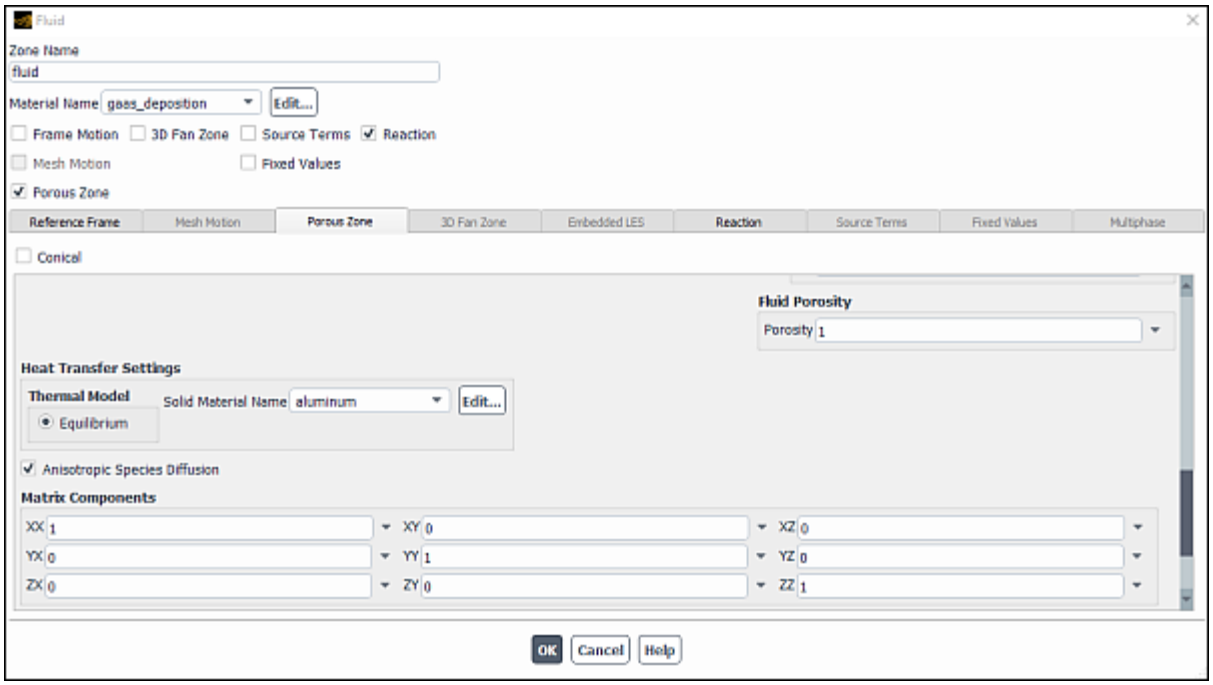
You can model anisotropic species diffusion in porous media. For the theory behind this modeling method, see Anisotropic Species Diffusion in the *Fluent Theory Guide*.

To account for anisotropic species diffusion in porous media simulations:

1. In the **Fluid** dialog box, enable **Porous Zone**.
2. In the **Porous Zone** tab, select the **Anisotropic Species Diffusion** check box (see Figure 8.36: Anisotropic Species Diffusion Matrix (p. 1648)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 8.36: Anisotropic Species Diffusion Matrix



3. Specify the **Matrix Components** for the anisotropic diffusion matrix $\mathbf{K}$.

   If you want to include the effect of porous media tortuosity, you can modify components of the anisotropic diffusion matrix accordingly.

   By default, $\mathbf{K}$ is the identity matrix that corresponds to isotropic diffusion.

8.9.4. Thermal Diffusion Coefficient Inputs

If you have enabled the **Thermal Diffusion** option in the Species Model Dialog Box (p. 4716), you can define the thermal diffusion coefficients in the Create/Edit Materials Dialog Box (p. 4833) as follows:

1. In the **Create/Edit Materials** dialog box for the mixture, select one of the following methods from the **Thermal Diffusion Coefficient** drop-down list:

   - Choose **kinetic-theory** to have Ansys Fluent compute the thermal diffusion coefficients using the empirically-based expression in Equation 7.17 in the *Fluent Theory Guide*. No further inputs are required for this option.

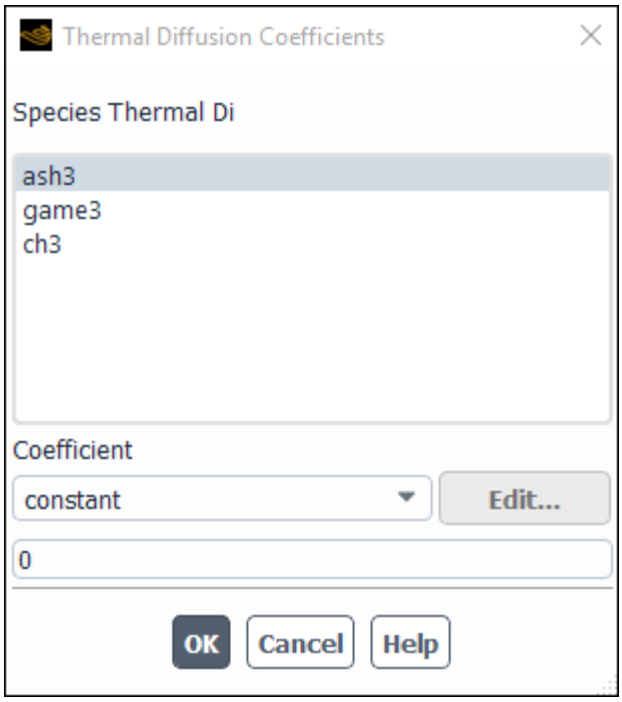
   - Choose **specified** to input the coefficient for each species in the Thermal Diffusion Coefficients Dialog Box (p. 4893) (Figure 8.37: The Thermal Diffusion Coefficients Dialog Box (p. 1649)) that opens automatically as further described.

   - Choose **user-defined** to use a user-defined function. More information about user-defined functions can be found in the Fluent Customization Manual.

2. (**specified** method only) For each species in the **Species Thermal Di** list of the **Thermal Diffusion Coefficients** dialog box, perform the following steps:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 8.37: The Thermal Diffusion Coefficients Dialog Box



a. Select the species in the **Species Thermal Di** list for which you are going to define the thermal diffusion coefficient.

b. Define $D_{T,i}$ for the selected species either as a constant value or as a polynomial function of temperature:

   - To define a constant diffusion coefficient, select **constant** (the default) in the drop-down list below **Coefficient**, and then enter the value in the field below the list.
   - To define a temperature-dependent diffusion coefficient, choose **polynomial** in the **Coefficient** drop-down list and then define the polynomial coefficients as described in Defining Properties Using Temperature-Dependent Functions (p. 1590).

For the theory behind this method, see Thermal Diffusion Coefficients in the *Fluent Theory Guide*.

8.10. Standard State Enthalpies

When you are solving a reacting flow using the finite-rate or eddy dissipation model, you must define the standard state enthalpy (also known as the formation enthalpy or heat of formation), h_j^0 for each species j. These inputs are used to define the mixture enthalpy as

$$H = \sum_j Y_j \left[\frac{h_j^0}{M_j} + \int_{T_{ref,j}}^{T} c_{p,j} dT \right] \tag{8.72}$$

where M_j is the molecular weight of the j^{th} species with units of kg/kmol and $T_{ref,j}$ is the reference temperature at which h_j^0 is defined. Standard state enthalpies are input in units of J/kg mol in SI units or in units of Btu/lb_mmol in British units.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For each species involved in the reaction (that is, each fluid material contained in the mixture material), you can set the **Standard State Enthalpy** and **Reference Temperature** in the Create/Edit Materials Dialog Box (p. 4833).

8.11. Standard State Entropies

If you are using the finite-rate model with reversible reactions (see Direct Use of Finite-Rate Kinetics (no TCI) in the Theory Guide), you must define the standard state entropy, s_j^0 for each species j. These inputs are used to define the mixture entropy as

$$S = \sum_j Y_j \left[\frac{s_j^0}{M_j} + \int_T^{T_{ref,j}} \frac{c_{p,j}}{T} dT \right] \tag{8.73}$$

where M_j is the molecular weight of the j^{th} species with units of kg/kmol and $T_{ref,j}$ is the reference temperature at which s_j^0 is defined. Standard state entropies are input in units of J/kmol-K in SI units or in units of Btu/lb_mmol-°R in British units.

For each species involved in the reaction (that is, each fluid material contained in the mixture material), you can set the **Standard State Entropy** and **Reference Temperature** in the Create/Edit Materials Dialog Box (p. 4833).

8.12. Unburnt Thermal Diffusivity

If you are modeling premixed combustion (see Modeling Premixed Combustion (p. 2534)), the fluid material in your domain should be assigned the properties of the unburnt mixture, including the thermal diffusivity (α in Equation 8.77 in the Theory Guide). α is defined as $k / \rho c_p$, and values at standard conditions can be found in combustion handbooks (for example, [80] (p. 5659)). To determine values at non-standard conditions, you must use a third-party 1D combustion program with detailed chemistry. You can set the **Unburnt Thermal Diffusivity** in the Create/Edit Materials Dialog Box (p. 4833).

8.13. Kinetic Theory Parameters

You may choose to define the following properties using kinetic theory when the ideal gas law is enabled:

- viscosity (for fluids)
- thermal conductivity (for fluids)
- specific heat capacity (for fluids)
- mass diffusion coefficients (for multi-species mixtures)

If you are using kinetic theory for a fluid's viscosity (Equation 8.28 (p. 1612)), you must input the kinetic theory parameters σ and ε / k_B for that fluid. These parameters are the Lennard-Jones parameters and are referred to by Ansys Fluent as the "characteristic length" and the "energy parameter" respectively.

- When kinetic theory is applied to calculation of a fluid's thermal conductivity only, no inputs are required.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- To calculate specific heat of a fluid using kinetic theory (Equation 8.67 (p. 1638)), you need to enter the degrees of freedom for the fluid material.
- If you use kinetic theory to define a mixture material's mass diffusivity (Equation 7.10 in the *Fluent Theory Guide*), you must input σ_i and $\left(\varepsilon / k_B\right)_i$ for each chemical species i.

For additional information, see the following section:

8.13.1. Inputs for Kinetic Theory

8.13.1. Inputs for Kinetic Theory

The procedure for using kinetic theory is as follows:

1. Select **kinetic-theory** as the property specification method for the **Viscosity**, **Thermal Conductivity**, or heat capacity **Cp** of a fluid material, or for the **Mass Diffusivity** of a mixture material.
2. If the material for which you have selected the kinetic theory method for one or more properties is a fluid material, you must set the kinetic theory parameters for each of the constituent species (fluid materials).

   The parameters to be set are as follows:

   - **L-J Characteristic Length**
   - **L-J Energy Parameter**
   - **Degrees of Freedom** (only required if kinetic theory is used for specific heat)

   See the beginning of this section to find out which parameters are required to calculate each property using kinetic theory.

Characteristic length is defined in units of Angstroms. The energy parameter is defined in units of absolute temperature. Degrees of freedom is a dimensionless input. All kinetic theory materials can be found in the literature (for example, [62] (p. 5658)).

8.14. Operating Pressure

Specification of the operating pressure affects your calculation in different ways for different flow regimes. This section presents information about the operating pressure, its relevance for different cases, and how to set it correctly.

For additional information, see the following sections:

8.14.1. The Significance of Operating Pressure

8.14.2. Operating Pressure, Gauge Pressure, and Absolute Pressure

8.14.3. Setting the Operating Pressure

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8.14.1. The Significance of Operating Pressure

Operating pressure is significant for incompressible ideal gas flows because it directly determines the density: the incompressible ideal gas law computes density as $\rho=\frac{p_{op}}{\frac{R}{M_w}T}$. You must therefore be sure to set the operating pressure appropriately.

In low-Mach-number compressible flow, the overall pressure drop is small compared to the absolute static pressure, and can be significantly affected by numerical roundoff. To understand why this is true, consider a compressible flow with $M<<1$. The pressure changes, Δp, are related to the dynamic head, $\frac{1}{2}\gamma pM^2$, where p is the static pressure and γ is the ratio of specific heats. This gives the simple relationship $\Delta p/\ p\sim M^2$, so that $\Delta p/\ p\rightarrow 0$ as $M\rightarrow 0$. Therefore, unless adequate precaution is taken, low-Mach-number flow calculations are very susceptible to roundoff error.

Operating pressure is significant for low-Mach-number compressible flows because of its role in avoiding roundoff error problems. Ensure that you set the operating pressure appropriately. You may want to specify a floating operating pressure instead of a constant operating pressure for low-Mach-number, time-dependent compressible flows with average pressure in the domain varying in time. See Floating Operating Pressure (p. 1735) for details.

Operating pressure is less significant for higher-Mach-number compressible flows. The pressure changes in such flows are much larger than those in low-Mach-number compressible flows, so there is no real problem with roundoff error and, therefore, no real need to use gauge pressure. In fact, it is common convention to use absolute pressures in such calculations. Since Ansys Fluent always uses gauge pressure, you can simply set the operating pressure to zero, making gauge and absolute pressures equivalent.

If the density is assumed constant or if it is derived from a profile function of temperature, the operating pressure is not used in the density calculation.

Note that the default operating pressure is 101325 Pa.

8.14.2. Operating Pressure, Gauge Pressure, and Absolute Pressure

Ansys Fluent avoids the problem of roundoff error (discussed in The Significance of Operating Pressure (p. 1652)) by subtracting the operating pressure (generally a large pressure roughly equal to the average absolute pressure in the flow) from the absolute pressure, and using the result (termed the gauge pressure). The relationship between the operating pressure, gauge pressure, and absolute pressure is shown below. The absolute pressure is simply the sum of the operating pressure and the gauge pressure:

$$p_{abs}=p_{op}+p_{gauge} \tag{8.74}$$

All pressures that you specify and all pressures computed or reported by Ansys Fluent are gauge pressures.

8.14.3. Setting the Operating Pressure

The criteria for choosing a suitable operating pressure are based on the Mach-number regime of the flow and the relationship that is used to determine density. For example, if you use the ideal gas law

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

in an incompressible flow calculation (for example, for a natural convection problem), you should use a value representative of the mean flow pressure.

To place this discussion in perspective, Table 8.1: Recommended Settings for Operating Pressure (p. 1653) shows the recommended approach for setting operating pressures. The default operating pressure is 101325 Pa.

Table 8.1: Recommended Settings for Operating Pressure

Density Relationship	Mach Number Regime	Operating Pressure
ideal gas law	$M > 0.1$	0 or ≈ mean flow pressure
ideal gas law	$M < 0.1$	≈ mean flow pressure
profile function of temperature	incompressible	not used
constant	incompressible	not used
incompressible ideal gas law	incompressible	≈ mean flow pressure

You will set the **Operating Pressure** in the Operating Conditions Dialog Box (p. 4926).

Setup → **Cell Zone Conditions** → **Operating Conditions...**

8.15. Using a Reference Pressure to Adjust the Gauge Pressure Field

For an incompressible flow or (for a steady-state case) a compressible flow in a cell zone or cell zone group that does not involve any pressure boundaries, Ansys Fluent can adjust the gauge pressure field after each iteration to keep it from floating. This is done using the pressure in the cell located at or nearest to the reference pressure location. The pressure value in this cell is subtracted from the entire gauge pressure field; as a result, the gauge pressure at the reference pressure cell is always zero.

Note:

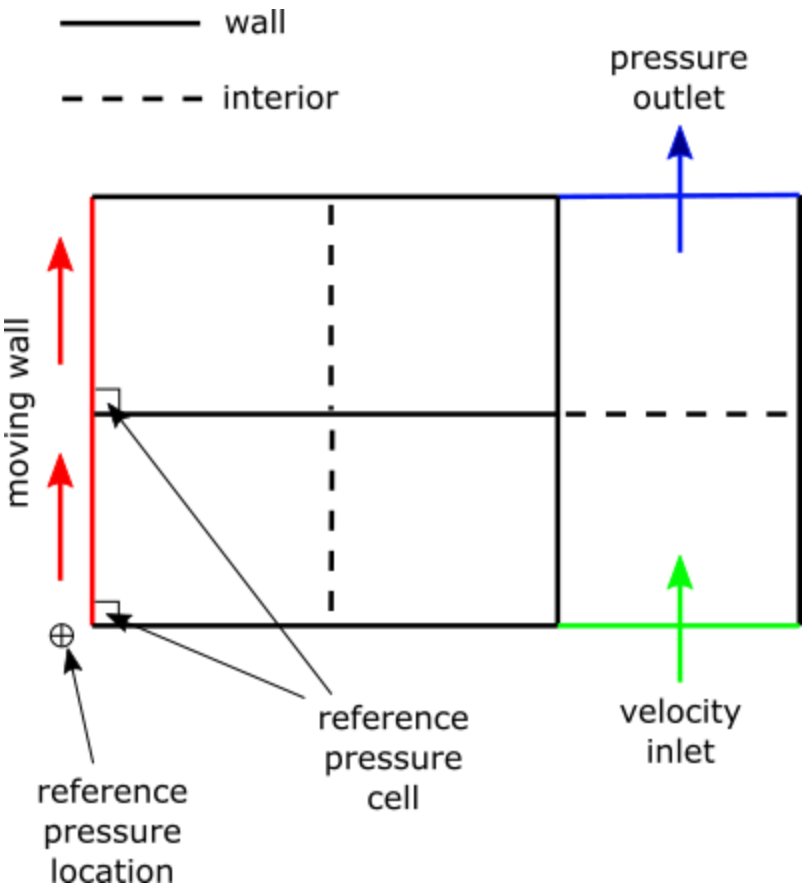
When you patch the pressure field for an incompressible flow or steady-state compressible flow, the reference pressure is subtracted in any closed domain after the patching. Therefore, the pressure field will be altered from your specified values.

By default, Fluent uses a reference pressure method that is designed for a mix of connected and disconnected fluid zones. Zones are considered connected if fluid can pass between them; this is the case when the zones are contiguous through boundary zones of type **interior**, **fan**, **porous-jump**, **radiator**, **rans-les-interface**, or **overset**, or share a mesh interface. A unique reference pressure cell will be used in each group of connected zones, and the presence of a pressure boundary in one group will not disqualify other groups from having the pressure adjusted.

An example of connected and disconnected fluid zones is shown in the following figure. Here, two lid-driven cavities are on the left, each consisting of a group of two cell zones enclosed by walls; there is also a channel on the right made up of two cell zones, which includes a pressure outlet. Fluent identifies reference pressure cells only in the left groups, and subtracts a unique value from the gauge pressure field within each of these groups. The gauge pressure field for the group on the right is not adjusted.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 8.38: Connected and Disconnected Cell Zones



The reference pressure cell of a particular group is the one that is at or closest to the reference pressure location. By default, this reference pressure location is defined as (0,0,0). There may be cases in which you might want to move the reference pressure location, perhaps locating it at a point where the absolute static pressure is known (for example, if you are planning to compare your results with experimental data). To change the location, enter new (**X**,**Y**,**Z**) coordinates for **Reference Pressure Location** in the Operating Conditions Dialog Box (p. 4926).

Setup → **Cell Zone Conditions** → **Operating Conditions...**

You can use the following text command to print the center coordinates of the reference pressure cells and the number of cell groups formed, the number of groups that will undergo pressure adjustment, and the cell zone IDs within each group:

`define` → `operating-conditions` → `used-ref-pressure-location`

Prior to Release 2020 R2, the default reference pressure method assumed that all of the cell zones are connected, which means that a single reference pressure cell is used in all of the zones, and the pressure adjustment is not performed anywhere if a pressure boundary exists in the case. For case files that were set up in such earlier releases, you can ensure that the reference pressure method accounts for connected and disconnected fluid zones (and thus always results in the most accurate static pressure calculations) by entering the following text command:

`define` → `operating-conditions` → `reference-pressure-method 2`

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8.16. Real Gas Models

Some engineering problems involve fluids that do not behave as ideal gases. For example, at very high-pressure or very low-temperature conditions (for example, the flow of a refrigerant through a compressor) the flow cannot typically be modeled accurately using the ideal-gas assumption. Therefore, the real gas model allows you to solve accurately for the fluid flow and heat transfer problems where the working fluid behavior deviates from the ideal-gas assumption.

Ansys Fluent provides three real gas options for solving these types of flows:

- Cubic Equation of State Models (p. 1658)
- The NIST Real Gas Models (p. 1675)
- The User-Defined Real Gas Model (p. 1693)

All the models allow you to solve for either a single-species fluid flow or a multiple-species mixture fluid flow.

In addition, real gas property (RGP) table files can be used to incorporate material properties from external sources into an Ansys Fluent simulation.

For additional information, see the following sections:

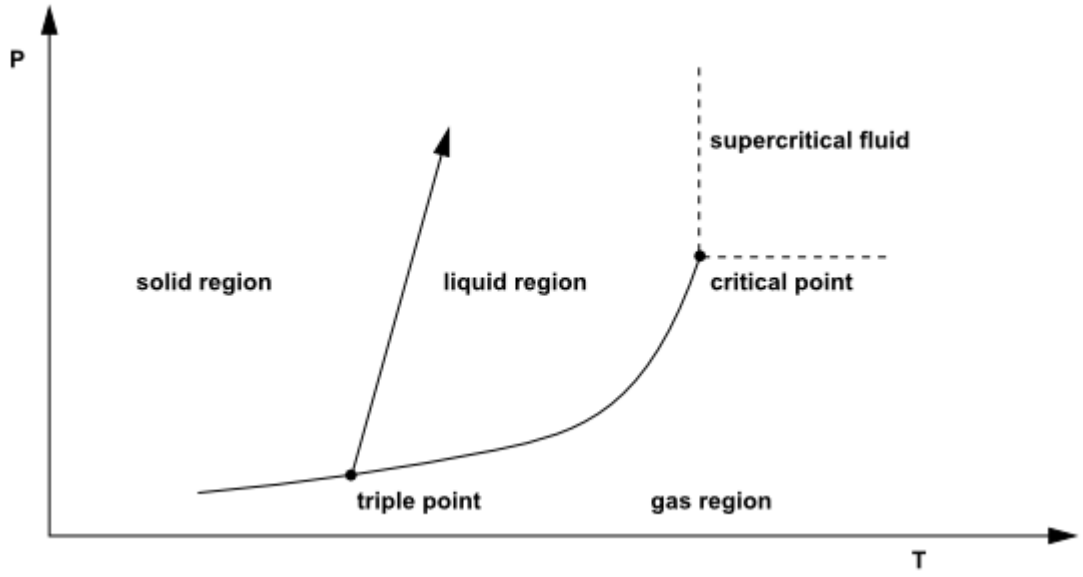
8.16.1. Introduction
8.16.2. Choosing a Real Gas Model
8.16.3. Cubic Equation of State Models
8.16.4. The NIST Real Gas Models
8.16.5. The User-Defined Real Gas Model
8.16.6. Using Real Gas Property (RGP) Table Files

8.16.1. Introduction

The states at which a pure material can exist can be graphically represented in diagrams of pressure vs. temperature (PT diagrams) and pressure vs. molecular or specific volume (PV diagrams). Homogeneous fluids are normally divided into two classes, liquids and gases. However the distinction cannot always be sharply drawn, because the two phases become indistinguishable at what is called the critical point. A typical pressure-temperature (PT) diagram of a pure material is shown in Figure 8.39: Typical PT Diagram of a Pure Material (p. 1656).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 8.39: Typical PT Diagram of a Pure Material



This figure shows the single phase regions, as well as the conditions of P and T where two phases coexist. Therefore the solid and the gas region are divided by the sublimation curve, the liquid and gas regions by the vaporization curve, and the solid and liquid regions by the fusion curve. The three curves meet at the triple point, where all three phases coexist in equilibrium. Although the fusion curve continues upward indefinitely, the vaporization curve terminates at the critical point. The coordinates of this point are called the critical pressure P_c and critical temperature T_c. These represent the highest temperature and pressure at which a pure material can exist in vapor-liquid equilibrium. At temperatures and pressures above the critical point, the physical property differences that differentiate the liquid phase from the gas phase become less defined. This reflects the fact that, at extremely high temperatures and pressures, the liquid and gaseous phases become indistinguishable. This new phase, which has some properties that are similar to a liquid and some properties that are similar to a gas, is called a supercritical fluid.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 8.40: Typical PV Diagram of a Pure Material

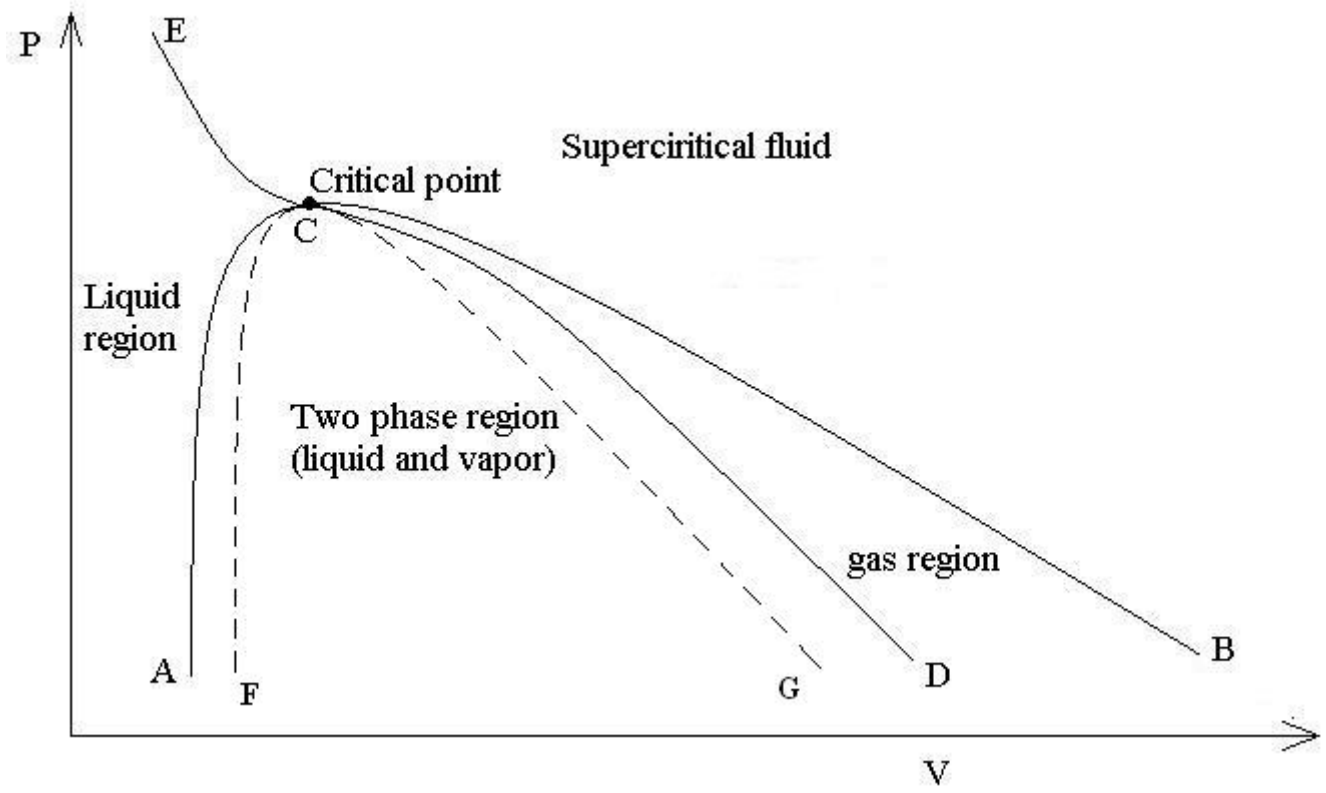


Figure 8.40: Typical PV Diagram of a Pure Material (p. 1657) presents a typical diagram of pressure versus molar or specific volume (PV diagram) of a pure material. The dome shaped curve ACD is called the saturation dome and separates the single phase regions in the diagram; curve AC represents the saturated liquid and curve CD the saturated vapor. The area under the saturation dome ACD is the two-phase region and represents all possible mixtures of vapor and liquid in equilibrium. Curve ECB is the critical isotherm and exhibits a horizontal inflection at point C at the top of the dome. This is the critical point. The specific volume corresponding to the critical point, is called the critical specific volume V_c. The conditions to the right of the critical isotherm ECB correspond to supercritical fluid. The dashed lines CF and CG in Figure 8.40: Typical PV Diagram of a Pure Material (p. 1657) represent the liquid and the vapor spinodal curves with the regions ACF and DCG between the saturation and spinodal lines representing the superheated liquid and supercooled vapor states, respectively. These states are called "metastable" because they exist temporarily in small local regions until phase change occurs. As an example, liquid metastable states may be formed in situations of fast depressurization, depending on the rate of depressurization and the disturbances that tend to make the liquid flash into vapor.

8.16.2. Choosing a Real Gas Model

The equation of state is the mathematical expression that relates pressure, molar or specific volume, and temperature for any pure homogeneous fluid in equilibrium states.

The simplest equation of state is the ideal gas law, which is approximately valid for the low pressure gas region of the PT and PV diagrams. Ideal gas behavior can be expected when

$$P/P_c \ll 1$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

or

$T/T_c > 2$ and $P/P_c < 1$

If your flow conditions correspond to either of those cases, you may use the ideal gas law in your simulation.

Another idealization, that of the incompressible fluid, can be employed for the low pressure region of the liquid phase. A constant density option is the appropriate selection in that case.

However, both of these approaches are not good approximations for flow conditions close to and beyond the critical point, where the fluid behavior cannot be described by the ideal gas, or the incompressible liquid assumptions. We refer to a fluid under those conditions as a real fluid, or a real gas and more complex relations are used for the determination of its physical and thermodynamic properties.

Ansys Fluent provides the following options for solving real fluid problems:

- The cubic equation of state models can be used to solve problems in the gas, liquid, and supercritical fluid regimes. The models are not available for the two-phase region under the phase dome. For further details see Cubic Equation of State Models (p. 1658).
- The NIST real gas model can be used to solve problems in the liquid, or gas and supercritical fluid regimes. The model does not allow modeling of the two-phase region. For further details see The NIST Real Gas Models (p. 1675).
- The user-defined real gas model allows you to solve problems in all regimes, as long as appropriate relationships are provided through the user-defined real gas functions. For further details see The User-Defined Real Gas Model (p. 1693).

The concepts presented in this section for pure materials are also extended to multicomponent mixtures with the introduction of appropriate composition-dependent parameters in the real gas equations of state and the material property models. All the real-gas modeling options above allow for either single-species or multicomponent flow modeling. In addition, you may solve reacting flow problems with the cubic equations of state models and the user-defined real gas functions.

8.16.3. Cubic Equation of State Models

8.16.3.1. Overview and Limitations

An equation of state is a thermodynamic equation, which provides a mathematical relationship between two or more state functions associated with the matter, such as its temperature, pressure, volume, or internal energy. One of the simplest equations of state for this purpose is the ideal gas law, which is roughly accurate for gases at low pressures and high temperatures. However, this equation becomes increasingly inaccurate at higher pressures and lower temperatures, and fails to predict condensation from a gas to a liquid.

Introduced in 1949, the Redlich-Kwong equation of state [118] (p. 5661) was a considerable improvement over other equations of that time. It is an analytic cubic equation of state and is still of interest primarily due to its relatively simple form. The original form is

$$P = \frac{RT}{V-b} - \frac{\alpha_0}{V\left(V+b\right)T_r^{0.5}} \tag{8.75}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where

P = absolute pressure (Pa)

R = universal gas constant

V = specific molar volume ($\mathrm{m}^3/\mathrm{kmol}$)

T = temperature (K)

T_r = reduced temperature $\frac{T}{T_c}$, where T_c is the critical temperature

α_0 and b are constants related directly to the fluid critical pressure and temperature

Many investigators have attempted to improve the accuracy of the Redlich-Kwong equation. Ansys Fluent has adopted the original form of the Redlich-Kwong equation, as well as the following modified forms:

- The Soave-Redlich-Kwong [147] (p. 5663) equation is a three-parameter equation of state, which can be applied for vapor, supercritical, and liquid property predictions. It has found wide acceptance mainly in the oil and gas industry and requires knowledge of the critical temperature, critical pressure, and acentric factor. It was developed by replacing the Redlich-Kwong attractive coefficient defined as $\alpha=\alpha_0/T_r^{0.5}$ with a two-parameter form $\alpha(T_r,\omega)$, where ω is the acentric factor.

- The Peng-Robinson equation [113] (p. 5661) is a three-parameter equation of state, also requiring the critical temperature, critical pressure and acentric factor parameters. It is thought to perform as well as the Soave-Redlich-Kwong equation, with an advantage in the prediction of the liquid densities.

- The Aungier-Redlich-Kwong [13] (p. 5655) equation provides improved predictions for vapor and supercritical fluids near the critical point, as well as for materials with a negative value of the acentric factor. The Aungier modified form is a four parameter equation and requires the critical specific volume in addition to the critical temperature, critical pressure and acentric factor.

The following limitations exist in Ansys Fluent for all cubic equation of state models:

- Pressure-inlets, mass flow-inlets, and pressure-outlets are the only inflow and outflow boundaries available for use with the real gas models.

- Non-reflecting boundary conditions are not compatible with the real gas models when using the density-based solver. If your model requires NRBC and a real gas model, you must use the pressure-based solver.

- The cubic equation of state real gas models are compatible with the Eulerian multiphase models.

- The cubic equation of state models are compatible with the Lagrangian Dispersed Phase Models. If you are modeling droplet or multicomponent particles, note that the current formulation does not take into account the near-critical point phenomena, which means that accurate results can be obtained for droplet temperatures below $T_{\lim}=0.9T_c$. See Using the Cubic Equation of State Models with the Lagrangian Dispersed Phase Models (p. 1672) for more details.

- The real gas models are not available with the premixed, inert, and composition PDF transport combustion models.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The cubic equation of state real gas models can be used with the following species models:
  - Species transport. Chemical reactions can be modeled with the finite rate and eddy dissipation models. Note that the **Dimension Reduction** model is not available with the real gas models.
  - Non-premixed model and partially-premixed model. Note that the **Compressibility Effects** option must be enabled in the **Species Model** dialog box in order for the real-gas models to be available. In addition the following restrictions apply when the non-premixed model is used together with a cubic equation of state real-gas model:
    → The empirical stream options cannot be used, as for the empirical species the critical properties cannot be defined.
    → Condensed species such as h2o<l> and c<s> are not supported and should be excluded from the PDF table, so ensure that you add all condensed species for your system in the excluded species list prior to the PDF table generation.
    The laminar flame speeds for the partially-premixed model are assumed to be the same as for ideal-gases.
- When the cubic equation of state models are applied for subcritical conditions near or under the phase dome, the two-phase flow is not modeled and either vapor or liquid state must be selected. Subcritical and supercritical states can co-exist in the same simulation.

8.16.3.2. Equation of State

The general form of pressure P for the cubic equation of state models is written as [13] (p. 5655) :

$$P=\frac{RT}{V-b+c}-\frac{\alpha}{\left(V^2+\delta V+\varepsilon\right)} \tag{8.76}$$

where

P = absolute pressure (Pa)

V = specific molar volume ($\mathrm{m}^3/\mathrm{kmol}$)

T = temperature (K)

R = universal gas constant

The coefficients α, b, c, δ, and ε are given for each equation of state as functions of the critical temperature T_c, critical pressure P_c, acentric factor ω and critical specific volume V_c. Note that the attractive coefficient α also has a temperature dependence, which varies for each equation of state model, and is commonly written as $\alpha=\alpha(T)$.

Redlich-Kwong Equation [123] (p. 5662):

$$\alpha(T)=\frac{\alpha_0}{\left(T/T_c\right)^{0.5}} \tag{8.77}$$

$$\alpha_0=\frac{0.42747R^2T_c^2}{P_c} \tag{8.78}$$

$$b=\frac{0.08664RT_c}{P_c} \tag{8.79}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The parameter δ is set equal to b, while c and ε are set to 0. The Redlich-Kwong equation is the simplest of the cubic equations of state in Ansys Fluent and requires two parameters only, the critical temperature T_c and the critical pressure P_c.

Soave-Redlich-Kwong Equation [147] (p. 5663):

$$\alpha(T)=\alpha_0[1+n(1-(T/T_c)^{0.5})]^2 \tag{8.80}$$

$$n=0.48+1.574\omega-0.176\omega^2 \tag{8.81}$$

α_0 and b are given by Equation 8.78 (p. 1660) and Equation 8.79 (p. 1660) respectively. As in the original Redlich-Kwong equation the parameter δ is set equal to b, while c and ε are set to 0. The Soave-Redlich-Kwong requires three parameters, the critical temperature T_c, the critical pressure P_c, and the acentric factor ω.

Peng-Robinson Equation [113] (p. 5661):

$$\alpha_0=\frac{0.457247R^2T_c^2}{P_c} \tag{8.82}$$

$$b=\frac{0.07780RT_c}{P_c} \tag{8.83}$$

The function $\alpha(T)$ is given by Equation 8.80 (p. 1661), with n provided in Equation 8.84 (p. 1661) as follows:

$$n=0.37464+1.54226\omega-0.26992\omega^2 \tag{8.84}$$

In the Peng-Robinson equation δ is set equal to 2b, ε is equal to $-b^2$, and c is set to 0.

Similar to the Soave-Redlich-Kwong equation, the Peng-Robinson equation is a three-parameter equation and requires the critical temperature T_c, the critical pressure P_c, and the acentric factor ω.

Aungier-Redlich-Kwong Equation [13] (p. 5655):

$$\alpha(T)=\alpha_0\left(\frac{T}{T_c}\right)^{-n} \tag{8.85}$$

$$n=0.4986+1.1735\omega+0.4754\omega^2 \tag{8.86}$$

α_0 and b are given by Equation 8.78 (p. 1660) and Equation 8.79 (p. 1660), respectively. As in the original Redlich-Kwong equation, the parameter δ is set equal to b and ε is set to 0. Parameter c is given by:

$$c=\frac{RT_c}{P_c+\frac{\alpha_0}{V_c(V_c+b)}}+b-V_c \tag{8.87}$$

The Aungier-Redlich-Kwong equation requires four parameters, namely the critical temperature T_c, the critical pressure P_c, the critical specific volume V_c, and the acentric factor ω.

8.16.3.3. Enthalpy, Entropy, and Specific Heat Calculations

Enthalpy, entropy, and specific heat are computed in terms of the relevant ideal gas properties and the departure functions. The departure function F_{dep} of any conceptual property F is defined as [118] (p. 5661)

$$F_{dep}=F_{ideal}(T,P)-F(T,P) \tag{8.88}$$

where F_{ideal} is the value of the property as computed from the ideal gas relations. The departure function F_{dep} can be derived from basic thermodynamic relations and the equation of state.

Following the above definition, the enthalpy H for the equations of state models is given by the following equations [13] (p. 5655):

$$H=H_{ideal}-\frac{H_{dep}}{MW} \tag{8.89}$$

$$H_{dep}=-PV+RT-\frac{T\frac{\partial a}{\partial T}-a}{\Delta}ln\left[\frac{2V+\delta+\Delta}{2V+\delta-\Delta}\right] \tag{8.90}$$

$$\Delta=\left(\delta^2-4\varepsilon\right)^{0.5} \tag{8.91}$$

where,

H_{ideal} = ideal gas enthalpy at temperature T (J/kg)

H_{dep} = departure enthalpy (J/kmol)

MW = mean molecular weight (Kg/kmol)

P = pressure (Pa)

V = specific molar volume (m^3/kmol)

R = universal gas constant

α, δ, and ε are computed using Equation 8.77 (p. 1660)– Equation 8.87 (p. 1661) depending on the equation of state model

See Equation 8.76 (p. 1660) for a description of other coefficients.

Similarly, the departure internal energy U_{dep} can be shown to be

$$U_{dep}=-\frac{T\frac{\partial a}{\partial T}-a}{\Delta}ln\left[\frac{2V+\delta+\Delta}{2V+\delta-\Delta}\right] \tag{8.92}$$

where

U_{dep} = departure internal energy (J/kmol)

T = temperature (K)

V = specific molar volume (m^3/kmol)

Δ is given by Equation 8.91 (p. 1662)

α, δ, and ε are computed using Equation 8.77 (p. 1660) – Equation 8.87 (p. 1661) depending on the equation of state model

The specific heat c_p can be computed from the ideal specific heat $c_{p,ideal}$ and the departure specific heat at constant volume $c_{v,dep}$ as follows:

$$c_p=c_{p,ideal}-\frac{c_{p,dep}}{MW} \tag{8.93}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$c_{p,dep}=c_{v,dep}-R-T\frac{\left(\partial V/\partial T\right)^2}{\partial V/\partial P} \tag{8.94}$$

where

MW = mean molecular weight (kg/kmol)

P = pressure (Pa)

T = temperature (K)

V = specific molar volume (m^3/kmol)

R = universal gas constant

In Equation 8.94 (p. 1663) $c_{v,dep}$ is computed by differentiating the equation of departure internal energy (Equation 8.92 (p. 1662)) with respect to T, and the partial derivatives of the specific volume are computed by differentiating Equation 8.76 (p. 1660) appropriately.

The entropy S is computed by

$$S=S_{ideal,0}-\frac{S_{dep}}{MW} \tag{8.95}$$

$$S_{dep}=-Rln\left(\frac{V-b+c}{V_0}\right)-\frac{\frac{da}{dT}}{\Delta}ln\left[\frac{2V+\delta+\Delta}{2V+\delta-\Delta}\right] \tag{8.96}$$

where

$S_{ideal,0}$ = ideal gas entropy at temperature T and reference pressure (J/kg/K)

V_0 = ideal gas specific molar volume at temperature T and the reference pressure (m^3/kmol)

P = pressure (Pa)

T = temperature (K)

V = specific molar volume (m^3/kmol)

MW = mean molecular weight (kg/kmol)

Δ is given by Equation 8.91 (p. 1662) and α, δ, and ε are computed using Equation 8.77 (p. 1660) – Equation 8.87 (p. 1661), depending on the equation of state model. Note that the pressure term in Equation 8.95 (p. 1663) cancels out as both $S_{ideal,0}$ and V_0 are evaluated at the reference pressure.

8.16.3.4. Critical Constants for Pure Components

Equations describing real-gas properties require the knowledge of the critical constants for pure components and mixtures. These consist of the critical temperature (T_c), critical pressure (P_c), critical specific volume (V_c), and the acentric factor (ω).

Several critical constants for fluid materials in the Ansys Fluent property database `propdb.scm` have been compiled from a variety of sources available in the open literature [118] (p. 5661), [107] (p. 5661), [108] (p. 5661), [141] (p. 5663), [142] (p. 5663), [148] (p. 5663), [11] (p. 5655).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For those fluid materials, for which the critical properties have not been found in the open literature, these have been estimated using the commercially available software CRANIUM by Molecular Knowledge Systems Inc. [1] (p. 5655) : `http://www.molknow.com/Cranium/cranium.htm`

Critical property values for many hydrocarbon and nitrogenous radical species have been obtained from Tang and Brezinsky [154] (p. 5663). Where the critical properties for the radicals were not available in the literature, these were estimated using a modification of the Joback method [118] (p. 5661). This assumes that the radical site constitutes a distinct group with zero group contribution and utilizes the group contribution values for stable species.

The critical properties of coal volatiles have been estimated assuming that the volatiles can be approximated by a mixture of CO, CO_2, H_2, CH_4, and C_2H_6 in such a way, that the atom composition and the net calorific value of the volatiles is similar to that of the assumed mixture. The critical properties of the lignite and biomass volatiles have been assumed equal to those of formaldehyde. The critical properties of diesel and jet-a fuels have been set equal to those of decane. The critical properties of kerosene have been set equal to those of dodecane.

8.16.3.5. Calculations for Mixtures

For the computation of properties in real-gas mixtures, Ansys Fluent follows the so-called pseudo-critical method. According to this method, the behavior and properties of a real gas mixture will be the same as that of a pure component, to which appropriate critical constants are assigned. These mixture critical constants are functions of the mixture composition and pure component critical properties, and are sometimes called pseudocritical constants, because their values are generally expected to be different from the true mixture critical constants that may be determined experimentally. However for computational purposes they are the appropriate critical constant values for the mixture. According to the pseudocritical method, Ansys Fluent applies Equation 8.76 (p. 1660)– Equation 8.96 (p. 1663) also for mixtures, where the critical temperature T_c, critical pressure P_c, critical specific volume V_c, and acentric factor ω, are replaced by the corresponding mixture critical constants, critical temperature T_{cm}, critical pressure P_{cm}, critical specific volume V_{cm}, and acentric factor ω_m.

The following options are available in Ansys Fluent for the calculation of the mixture pseudocritical constants:

- The simplest rule for computing the pseudocritical constants C_{cm} for a real gas mixture is the mole fraction average [118] (p. 5661). This method is recommended for mixtures where the pure component critical properties for all components are not very different:

$$C_{cm} = \sum_{i=1}^{k} x_i C_{ci} \tag{8.97}$$

  where

  C_{cm} = mixture pseudocritical constant (temperature, pressure, specific volume or acentric factor)

  C_{ci} = critical constant of component i (temperature, pressure, specific volume or acentric factor)

  x_i = mole fraction of component i

  k = number of components in mixture

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- An alternative approach is based on the one-fluid van der Waals mixing rules as expressed in [123] (p. 5662). According to this approach, in order to apply the equation of state models to mixtures, the coefficients a and b in Equation 8.76 (p. 1660) are replaced by composition-dependent expressions as follows:

$$(\alpha_m)^{0.5} = \sum_i x_i (\alpha_i)^{0.5} \tag{8.98}$$

$$b_m = \sum_i x_i b_i \tag{8.99}$$

where

x_i = mole fraction of species i

With the appropriate expressions from Equation 8.77 (p. 1660)– Equation 8.87 (p. 1661) for each equation of state, and assuming a mixture acentric factor ω_m for the evaluation of parameter n in Equation 8.81 (p. 1661), Equation 8.84 (p. 1661), and Equation 8.86 (p. 1661), the mixing rules Equation 8.98 (p. 1665) and Equation 8.99 (p. 1665) can be rearranged to yield direct expressions of the mixture critical properties as functions of the mole fractions and the component critical properties [13] (p. 5655).

The resulting expressions for the mixture critical specific temperature T_{cm} are as follows:

– Soave-Redlich-Kwong and Peng-Robinson models

$$T_{cm} = \frac{\left[\sum_i \left(x_i \frac{T_{ci}}{P_{ci}^{0.5}}\right)\right]^2}{\sum_i \left(\frac{x_i T_{ci}}{P_{ci}}\right)} \tag{8.100}$$

– Redlich-Kwong model and Aungier-Redlich-Kwong model:

$$T_{cm}^{1+n} = \frac{\left[\sum_i \left(x_i \sqrt{\frac{T_{ci}^{(2+n)}}{P_{ci}}}\right)\right]^2}{\sum_i \left(\frac{x_i T_{ci}}{P_{ci}}\right)} \tag{8.101}$$

where for the Aungier-Redlich-Kwong model n is obtained from Equation 8.86 (p. 1661) as function of the mixture acentric factor ω_m. For the Redlich-Kwong model n=0.5.

The mixture critical specific pressure P_{cm} is computed as:

$$P_{cm} = \frac{T_{cm}}{\sum_i \left(\frac{x_i T_{ci}}{P_{ci}}\right)} \tag{8.102}$$

The mixture critical specific volume V_{cm} is computed as:

$$V_{cm} = \sum_I \frac{x_i P_{ci} V_{ci}}{T_{ci}} \left(\frac{T_{cm}}{P_{cm}}\right) \tag{8.103}$$

The notation for Equation 8.100 (p. 1665) to Equation 8.103 (p. 1665) is

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

T_{cm} = mixture pseudocritical temperature (K)

P_{cm} = mixture pseudocritical pressure (Pa)

V_{cm} = mixture pseudocritical molar volume (m^3/kmol)

T_{ci} = critical temperature for component i (K)

P_{ci} = critical pressure for component i (Pa)

V_{ci} = critical molar volume for component i (m^3/kmol)

x_i = mole fraction for component i

8.16.3.5.1. Using the Cubic Equation of State Real Gas Models

For single or multicomponent flows, you will enable the cubic equation of state real gas models by selecting **real-gas-soave-redlich-kwong**, **real-gas-peng-robinson**, **real-gas-aungier-redlich-kwong**, or **real-gas-redlich-kwong** from the **Density** drop-down list in the **Create/Edit Materials** dialog box.

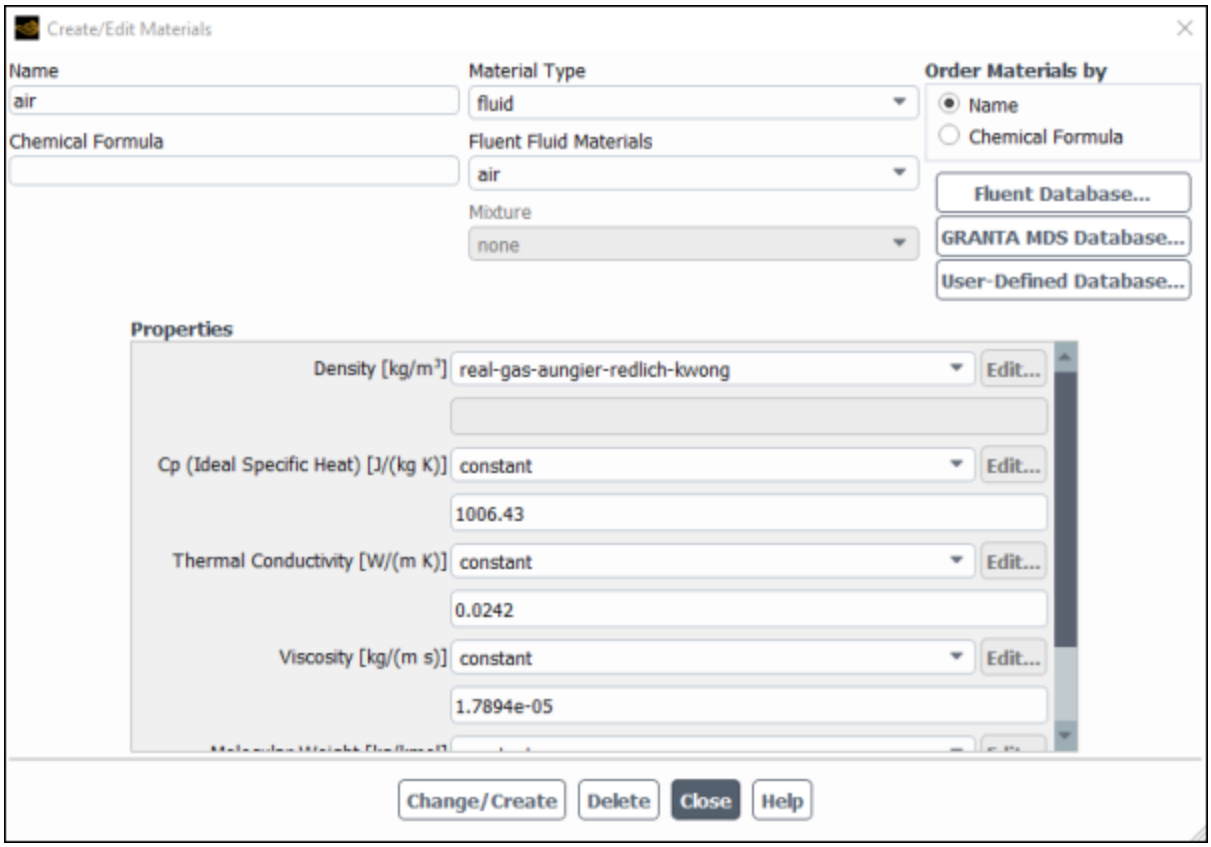
Setup → Materials → Create/Edit...

The required inputs for the cubic equation of state real gas models for single component flow and mixtures are described below.

Single Component Flow

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 8.41: The Cubic Equation of State Model for a Real-Gas Fluid



When any of the cubic equation of state models is enabled, enter the following material properties in the dialog box:

- ideal specific heat
- molecular weight
- standard state entropy
- reference temperature
- critical temperature
- critical pressure
- critical specific volume
- acentric factor

Important:

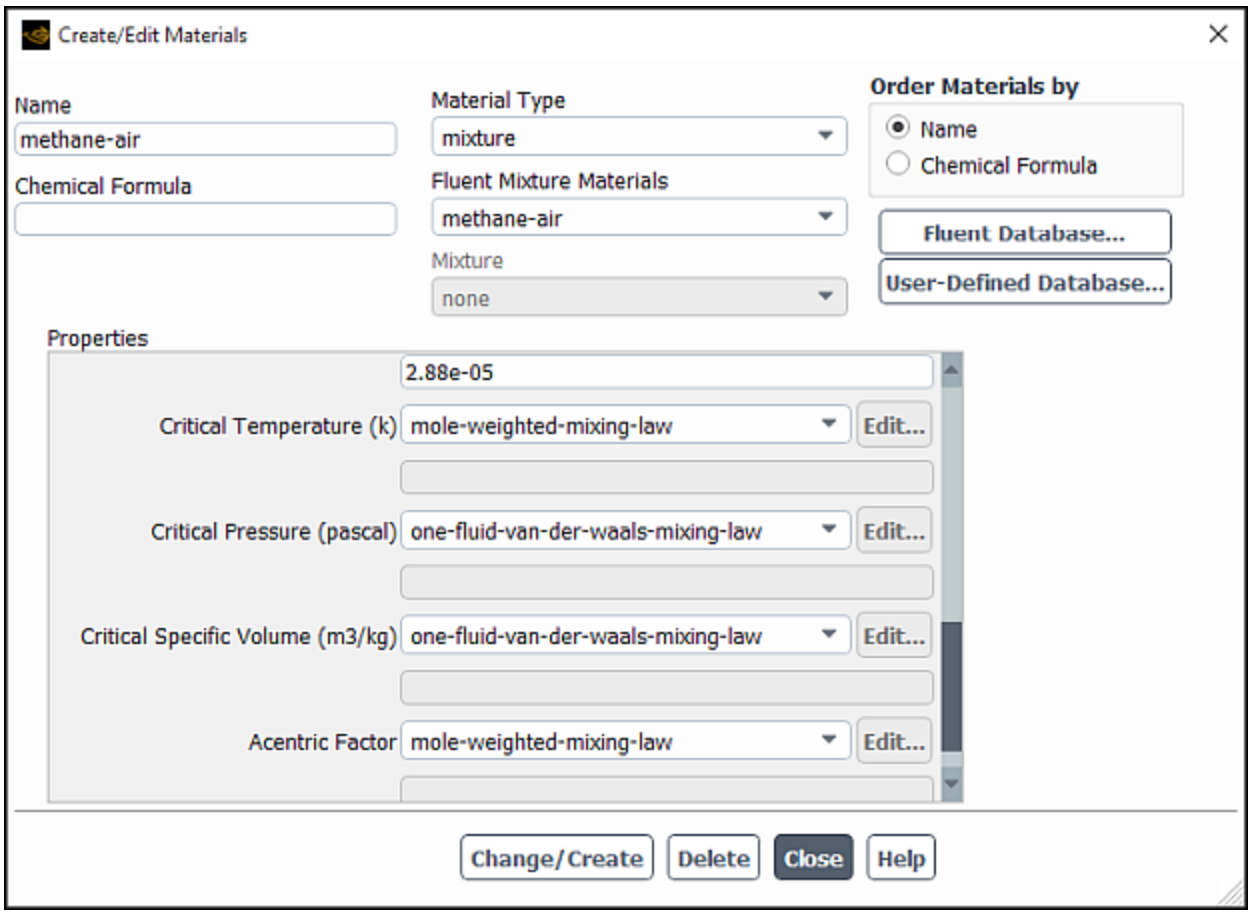
Your inputs for the specific heat in the **Materials** dialog box will now be used to compute the ideal property functions H_{ideal}, $c_{p,ideal}$, and $S_{ideal,0}$ in Equation 8.89 (p. 1662), Equation 8.93 (p. 1662), and Equation 8.95 (p. 1663), respectively. In Ansys Fluent the de-

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

parture properties will be computed and added to the ideal part, to yield the real gas specific heat, enthalpy, and entropy.

Mixtures

Figure 8.42: The Cubic Equation of State Model for a Real-Gas Mixture



When one of the cubic equation of state models is selected from the **Density** drop-down list, specify the following material properties for the mixture material in the dialog box:

- ideal specific heat
- critical temperature
- critical pressure
- critical specific volume
- acentric factor

You also need to enter the following material properties for each of the mixture components in the dialog box:

- molecular weight
- standard state entropy

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- reference temperature

When you are modeling a real-gas mixture, the following methods are available for the mixture critical constants:

- **constant**: defines a constant critical temperature, critical pressure, critical specific volume, or acentric factor for the mixture material.
- **mole-weighted-mixing-law**: applies Equation 8.97 (p. 1664) for critical temperature, critical pressure, critical specific volume, or acentric factor for the mixture material.
- **one-fluid-van-der-waals-mixing-law** applies Equation 8.100 (p. 1665) and Equation 8.101 (p. 1665) for the mixture critical temperature (depending on the real-gas model), Equation 8.102 (p. 1665) for the mixture critical pressure, and Equation 8.103 (p. 1665) for the mixture molar volume.

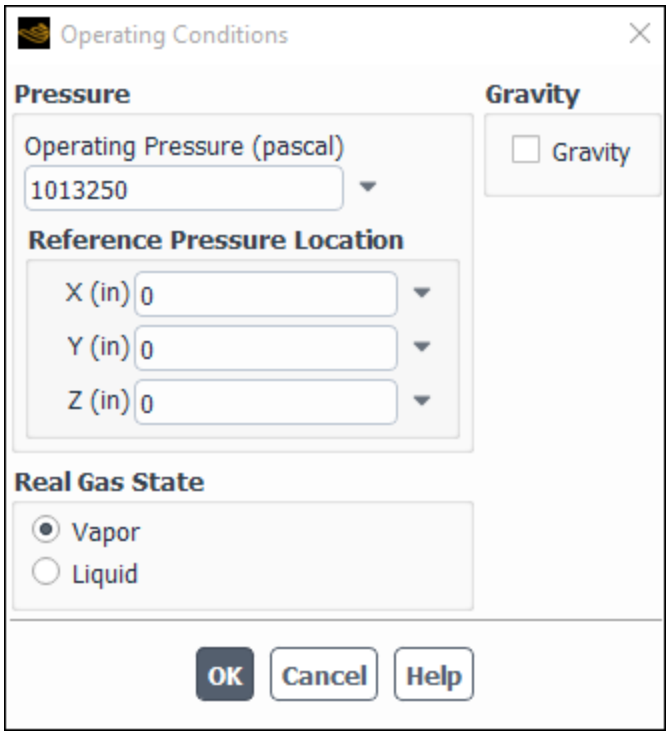
Important:

- Ensure to click the **Change/Create** button so that all the above mentioned properties are uploaded and are visible in the interface.
- If you have selected **mixing-law** for the mixture ideal specific heat you will also need to enter the ideal specific heat values for the individual mixture components. If you have not selected **constant** as the option for any of the critical properties, you must enter the corresponding pure component critical properties for the mixture components.

If the operating conditions in your model are in the subcritical regime, select **Vapor** or **Liquid** as the **Real Gas State** in the **Operating Conditions** dialog box (Figure 8.43: The Operating Conditions for a Real Gas State (p. 1670)). Alternatively, you can use the `define/operating-conditions/set-state` text command. Note that the default is **Vapor** and therefore **Vapor** is assumed if no changes are made to the **Real Gas State** settings. If the operating conditions in your model are entirely in the supercritical regime, this setting will have no effect.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 8.43: The Operating Conditions for a Real Gas State



In addition, you may specify the state for a specific fluid zone or a specific phase (if you are using multiphase modeling) by typing the following text command at the Ansys Fluent console prompt:

```
> define boundary-conditions modify-zones change-zone-state
Select a name/id from fluid zones list [(liquid-zone fluid-1)] liquid-zone
Set zone real-gas state:
  -1:use global setting
  0:liquid
  1:vapor
[-1]  0
```

8.16.3.5.2. Solution Strategies and Considerations for Cubic Equations of State Real Gas Models

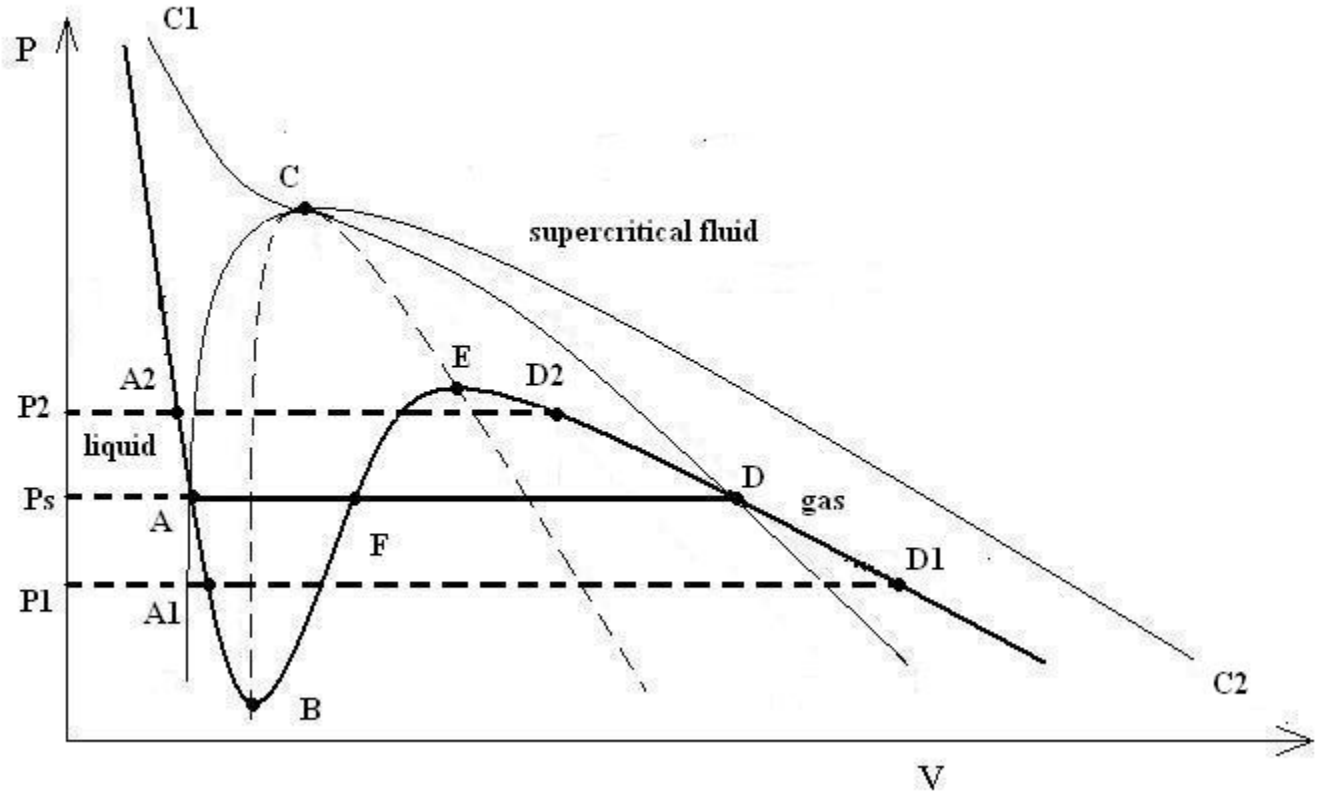
The flow modeling of real-gas flow is more complex and challenging than simple ideal-gas flow. Therefore, the solution might converge at a slower rate with real-gas flow than when running ideal-gas flow. It is recommended that you first attempt to converge your solution using first-order discretization then switch to second-order discretizations and re-iterate to convergence.

Special considerations apply if the operating regime in your model is fully or partly subcritical, where the physical state may be vapor, liquid, or a vapor/liquid mixture. In the cubic EOS real-gas model, the phase state is determined by the selection of the cubic root to calculate the molar-volume. This is illustrated in Figure 8.44: The PV Diagram for the Cubic Equation of State Real Gas Model (p. 1671), which shows a pressure versus molar volume (PV) diagram, with a sub-critical isotherm ABFED at temperature T calculated from a cubic EOS. Curve C1CC2 represents the critical isotherm and curve ACD the saturation dome. Points A, F, and D represent the three roots of the EOS at the saturation pressure Ps, where A corresponds to the molar volume of saturated liquid, D to the molar volume of saturated vapor and point F does not have a physical significance. Points A1 and D1 correspond to the liquid and vapor molar volumes at pressure P1, which is lower than the saturation pressure. The liquid and vapor molar volumes at pressure P2,

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

which is higher than the saturation pressure, are marked as A2 and D2 respectively. Points B and E, where the partial derivatives of pressure with respect to volume $\left(\partial P/\partial V\right)_T$ are 0, are called spinodal points. The loci of these points for all subcritical temperatures, the spinodal curve, is shown with the dashed curve BCE and sets the boundary beyond which the equation of state is no longer valid, because the local derivative of pressure with respect to volume becomes positive. State points inside the dome, up to the spinodal curve, are called "metastable" because normally they only exist temporarily in small local regions until phase change occurs.

Figure 8.44: The PV Diagram for the Cubic Equation of State Real Gas Model



It is important to realize that the current implementation of the cubic equations of state real gas model does not determine the saturation conditions and does not model the two-phase flow where liquid and vapor coexist. In the subcritical regime and for conditions where the cubic EOS has three roots, the phase state selection is controlled by your input of **Vapor** or **Liquid** for **Real Gas State** in the **Operating Conditions** dialog box (Figure 8.43: The Operating Conditions for a Real Gas State (p. 1670)). The default setting is **Vapor**, which corresponds to the state points to the right of the vapor spinodal. With reference to Figure 8.44: The PV Diagram for the Cubic Equation of State Real Gas Model (p. 1671), for the operating point at temperature T and pressure P1, if the **Real Gas State** is set to **Vapor**, the molar volume at point D1, which corresponds to superheated vapor, will be selected in the calculation. On the other hand, if you have selected **Liquid**, the molar volume of point A1 will be taken, and the corresponding state will be metastable super-heated liquid. Similarly for pressure P2, which is higher than the saturation pressure Ps, if you select **Liquid** for **Real Gas State**, the liquid molar volume at A2 will be computed, and if you select **Vapor** the molar volume will correspond to the subcooled vapor state point D2.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In case the calculations fall inside the saturation dome, the solver will not limit the solution, but if conditions are predicted that extend beyond the vapor spinodal curve a warning will be issued:

```
temperature is below the spinodal point in 12 cells on zone 3.
```

Cubic equations of state real gas models are not available for two-phase flows but can be applied to conditions of supercritical pressure $P>P_c$ and subcritical temperature $T<T_c$, where the fluid is in the liquid state, and the supercritical liquid co-exists with gas and supercritical fluid in the same simulation. In those cases, phase change may take place, without any of the flow conditions falling inside the saturation dome.

For multicomponent simulations, when **Diffusion Energy Source** is enabled in the **Species Model** dialog box, the species energy diffusion is by default suppressed in the supercritical liquid regime and across the gas-liquid boundary. The diffusion energy source can be included in the liquid regime using the `define/models/species/liquid-energy-diffusion?` text command.

8.16.3.5.3. Using the Cubic Equation of State Models with the Lagrangian Dispersed Phase Models

If your simulation contains a liquid stream, the appropriate modeling approach in the various operating condition regimes is as follows:

1. For $T>T_c$ a liquid phase does not exist.

2. In the region $P>P_c$, you can define the flow streams directly in the boundary conditions by setting the appropriate pressure and temperature and the properties will be computed directly by the cubic EOS.

3. For $P<P_c$ or $P>P_c$, a stream can exist in liquid phase when its temperature $T<T_c$. If you would like to model phase change in this regime, the following recommendations apply:

   - The DPM droplet and multicomponent models are adequate and recommended for the conditions away from the critical point. This regime can be defined as $T<0.9T_c$, where the liquid physical properties can be assumed independent of pressure.

   - The region $T_c>T>0.9T_c$ is characterized by near-critical-point phenomena, such as strong liquid density and specific heat dependence on both temperature and pressure. The DPM model can also be used in this regime, but you should be cautious, as it will not take into consideration the near-critical-point behavior. In addition, the applicability of the evaporation and boiling rate equations is questionable in this regime.

   - If the pressure in your model is above the critical point, it is recommended to use the **compressible-liquid** method for **Density** of the droplet material.

The temperature $T_{\lim}=0.9T_c$ gives an indication of the maximum droplet temperature for applicability of the DPM models for each droplet material. These temperature limits are listed in Table 8.2: Temperature Limits for Droplet Materials in Ansys Fluent Database prodb.scm (p. 1673) for many of the droplet materials in Ansys Fluent's `propdb.scm` materials database. For super-

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

critical pressures ($P>P_c$), the DPM models can still be used provided the droplet temperatures remain below the limit T_{lim}.

Table 8.2: Temperature Limits for Droplet Materials in Ansys Fluent Database prodb.scm

Material	Tc (K)	Pc (MPa)	Normal BP (K)	Tlim (K)
Argon	150.86	4.89	87.30	135.77
Benzene	562.00	4.89	353.00	505.80
Helium	5.30	0.23	4.20	4.77
Hydrogen	32.98	1.30	20.40	29.68
Methyl-alcohol	512.00	8.10	338.00	460.80
Heptanes	540.00	2.74	371.00	486.80
Hexane	507.00	3.02	342.00	456.30
Octane	569.00	2.49	399.00	512.10
Pentane	470.00	3.37	309.00	423.00
Nitrogen	126.00	3.40	77.40	113.40
Oxygen	154.00	5.04	90.20	138.60
Toluene	592.00	4.11	384.00	532.80
Water	647.00	22.00	373.00	582.30

For high pressure simulations the boiling point will be different from the normal boiling point, and for varying pressure applications the boiling point will vary with the droplet location in the domain.

When a cubic equation of state real gas model is enabled in a simulation that includes evaporating droplet particles, the boiling point is calculated from the vapor pressure data directly, as the temperature where the saturation vapor pressure equals the domain pressure. In addition, the latent heat of the evaporating or boiling droplet will vary with the droplet temperature.

The latent heat at temperature T_p is given by

$$H_{lat_T} = -\int_{T_p}^{T_{bp}} c_{p,g} dT + H_{lat} + \int_{T_p}^{T_{bp}} c_{p,p} dT \tag{8.104}$$

where T_{bp} is the normal boiling point and H_{lat} is the latent heat at the normal boiling point.

In the **Create/Edit Materials** dialog box you must enter the **Normal Boiling Point (NBP)** and the **Latent Heat at NBP** for the **droplet-particle Material Type**. These inputs will be used for calculating the **Latent Heat** at the reference temperature (see Equation 12.509) and the latent heat in the droplet energy balance during vaporization and boiling according to Equation 8.104 (p. 1673).

Important:

The constant property option is disabled for the **Saturation Vapor Pressure** property when a real gas model is used in the simulation. Also, ensure to enter

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the appropriate droplet saturation vapor pressure data to cover the complete pressure/temperature range in your model.

Finally when a cubic equation of state real-gas model is enabled in a simulation with droplet models, the condition for switching from the vaporization to the boiling law will be

$$P_{sat} > P \tag{8.105}$$

where P_{sat} is the saturation vapor pressure and P is the domain pressure. If $P_{sat} < P$ while in the boiling law, the model will switch back to the vaporization law. Under supercritical pressure conditions ($P > P_c$), the vaporization models are applicable at droplet temperatures below the critical point, and the switching condition from vaporization to boiling $P_{sat} > P_c$ is never met because the vapor pressure curve is defined only up to the critical point.

For the multicomponent droplets in the supercritical pressure regime, failure of the saturation temperature calculation algorithm may indicate that the droplet has approached the critical temperature, provided that you have entered accurate vapor pressure data for all components. In such a case, you can use the following text command:

```
define/models/dpm/options/treat-multicomponent-saturation-temperature-
failure?

Dump multicomponent particle mass if the saturation temperature
calculation fails? [no] y
```

When this option is enabled, Ansys Fluent dumps the particle mass into the continuous phase if the saturation temperature calculation fails.

8.16.3.5.4. Postprocessing the Cubic Equations of State Real Gas Model

All postprocessing functions properly report and display the current thermodynamic and transport properties of the selected real gas model. The thermodynamic and transport properties controlled by the cubic equations of state real gas model include the following:

- density
- enthalpy
- entropy
- sound speed
- specific heat
- any quantities that are derived from the properties listed above (for example, total quantities, ratio of specific heats)

In addition to the properties listed above, you can also report

- compressibility factor
- reduced temperature
- reduced pressure

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- spinodal temperature
- subcritical condition

If you are modeling a real-gas mixture you can report the composition-dependent mixture critical properties

- critical temperature
- critical pressure
- critical specific volume
- acentric factor

8.16.4. The NIST Real Gas Models

The NIST real gas models use the National Institute of Standards and Technology (NIST) Thermodynamic and Transport Properties of Refrigerants and Refrigerant Mixtures Database Version 9.1 (REFPROP v9.1) to evaluate thermodynamic and transport properties of approximately 125 fluids or a mixture of these fluids.

The REFPROP v9.1 database is a shared library that is dynamically loaded into the solver when you enable one of the NIST real gas models in an Ansys Fluent session. Once the NIST real gas model is activated, control of relevant property evaluations is relinquished to the REFPROP database. All postprocessing functions will properly report and display the current thermodynamic and transport properties of the real gas.

8.16.4.1. Limitations of the NIST Real Gas Models

The following limitations exist for the NIST real gas model:

- The NIST real gas model assumes that the fluid you will be using in your Ansys Fluent computation is superheated vapor, supercritical fluid, or liquid. Note that subcritical flow conditions, where vapor coexists with liquid in two-phase flow, are not supported. In addition, all fluid zones must contain the real gas; you cannot include a real gas and another fluid in the same problem.
- Pressure-inlet, mass flow-inlet, and pressure-outlet are the only inflow and outflow boundaries available for use with the real gas models.
- Non-reflecting boundary conditions are not compatible with the real gas models when using the density-based solver. If your model requires NRBC and a real gas model, you must use the pressure-based solver.
- The mixture flow does not permit chemical reactions with the NIST real gas model.
- The multicomponent NIST real gas models cannot be used with any of the multiphase models. You can, however, use a NIST material in single-component multiphase flows. The model is compatible with the Lagrangian Dispersed Phase Models only for the massless and inert particle types.
- You cannot modify material properties in the REFPROP database libraries, or add custom materials to the NIST real gas model.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Only one pure fluid or one multiple-species mixture in a simulation may use the NIST real gas model. Multiple NIST materials may be created, but those participating in the simulation must all refer to a unique NIST fluid. This is a third-party limitation of the NIST/REFPROP module.

8.16.4.2. The REFPROP v9.1 Database

The NIST real gas model supports 125 fluids from the REFPROP database. These include pure fluids (with the file extension `.fld`) and pseudo-fluids (with the file extension `.ppf`). The fluids that are supported by REFPROP v9.1 and used in the NIST real gas model are listed in Table 8.3: Fluids Supported by REFPROP v9.1 (p. 1676) (the corresponding property file name appears in parentheses, where it does not coincide with the fluid name).

The REFPROP v9.1 database employs accurate pure-fluid equations of state that are available from NIST. These equations are based on three models:

- modified Benedict-Webb-Rubin (MBWR) equation of state
- Helmholtz-energy equation of state
- extended corresponding states (ECS)

For a fluid that consists of a multispecies-mixture the thermodynamic properties are computed by employing mixing-rules applied to the Helmholtz energy of the mixture components.

Important:

The database does not include transport property models for the species marked with * in Table 8.3: Fluids Supported by REFPROP v9.1 (p. 1676). As a result the NIST real gas model with those species can only be used for modeling inviscid flow.

Table 8.3: Fluids Supported by REFPROP v9.1

1-butene	nitrogen

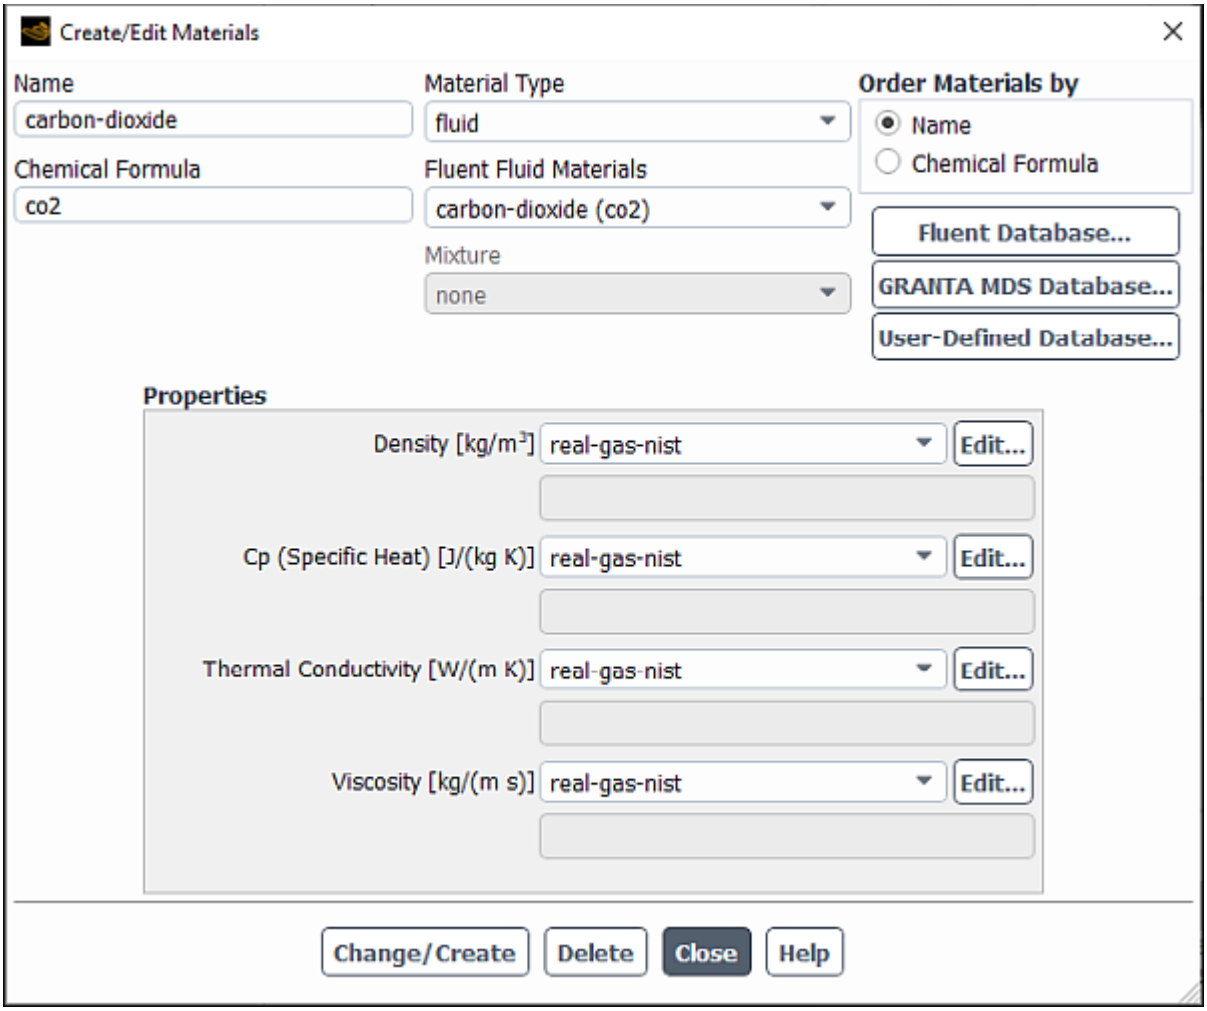
8.16.4.3. Using the NIST Real Gas Models

The NIST real gas model can be enabled for pure fluids by selecting `real-gas-nist` for **Density** on the **Create/Edit Materials** dialog box.

Physics → **Materials** → **Create/Edit...**

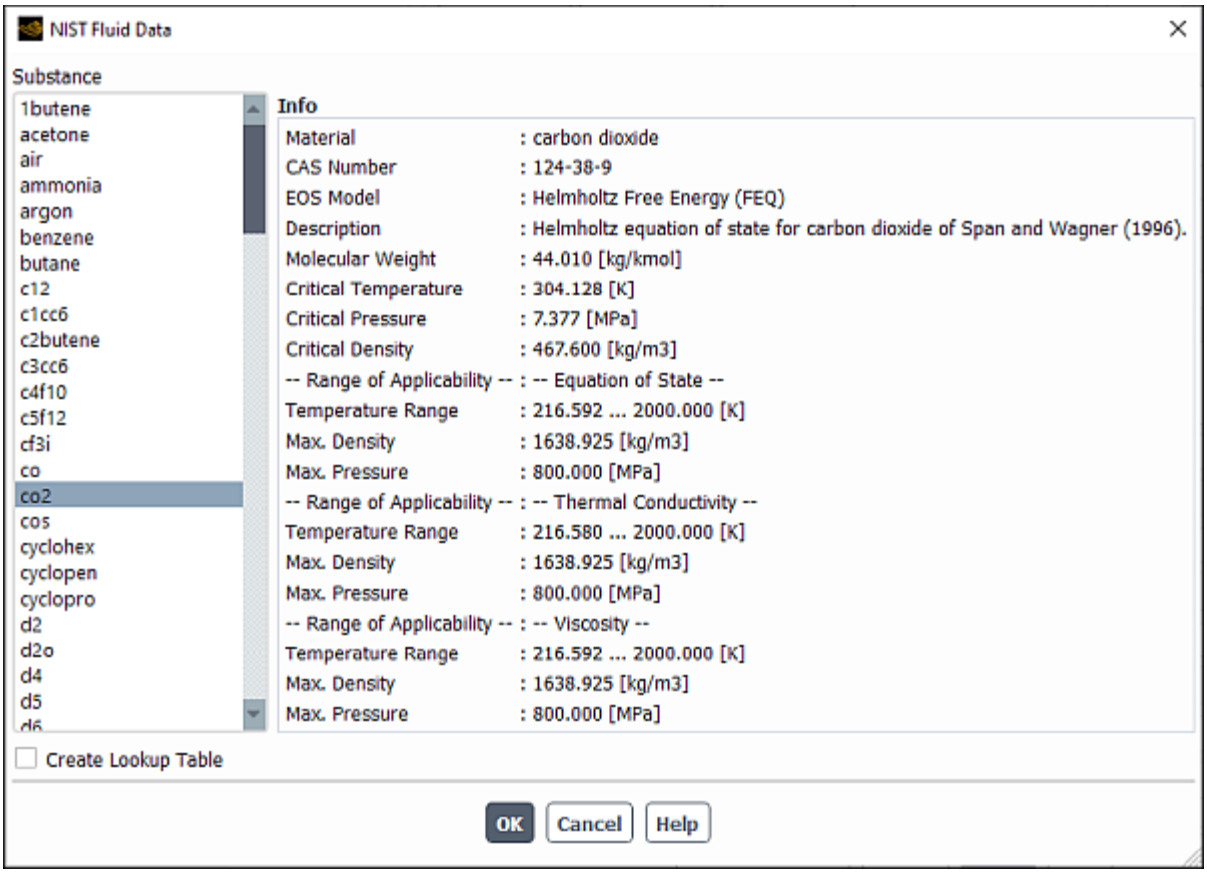
Figure 8.45: The Create/Edit Materials Dialog Box with NIST Model Enabled



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When you select **Edit...** for **Density**, you will be prompted to select the appropriate NIST data from the **NIST Fluid Data** dialog box. After selecting a valid fluid, properties for the specified material, including its applicable pressure and temperature ranges, will be displayed.

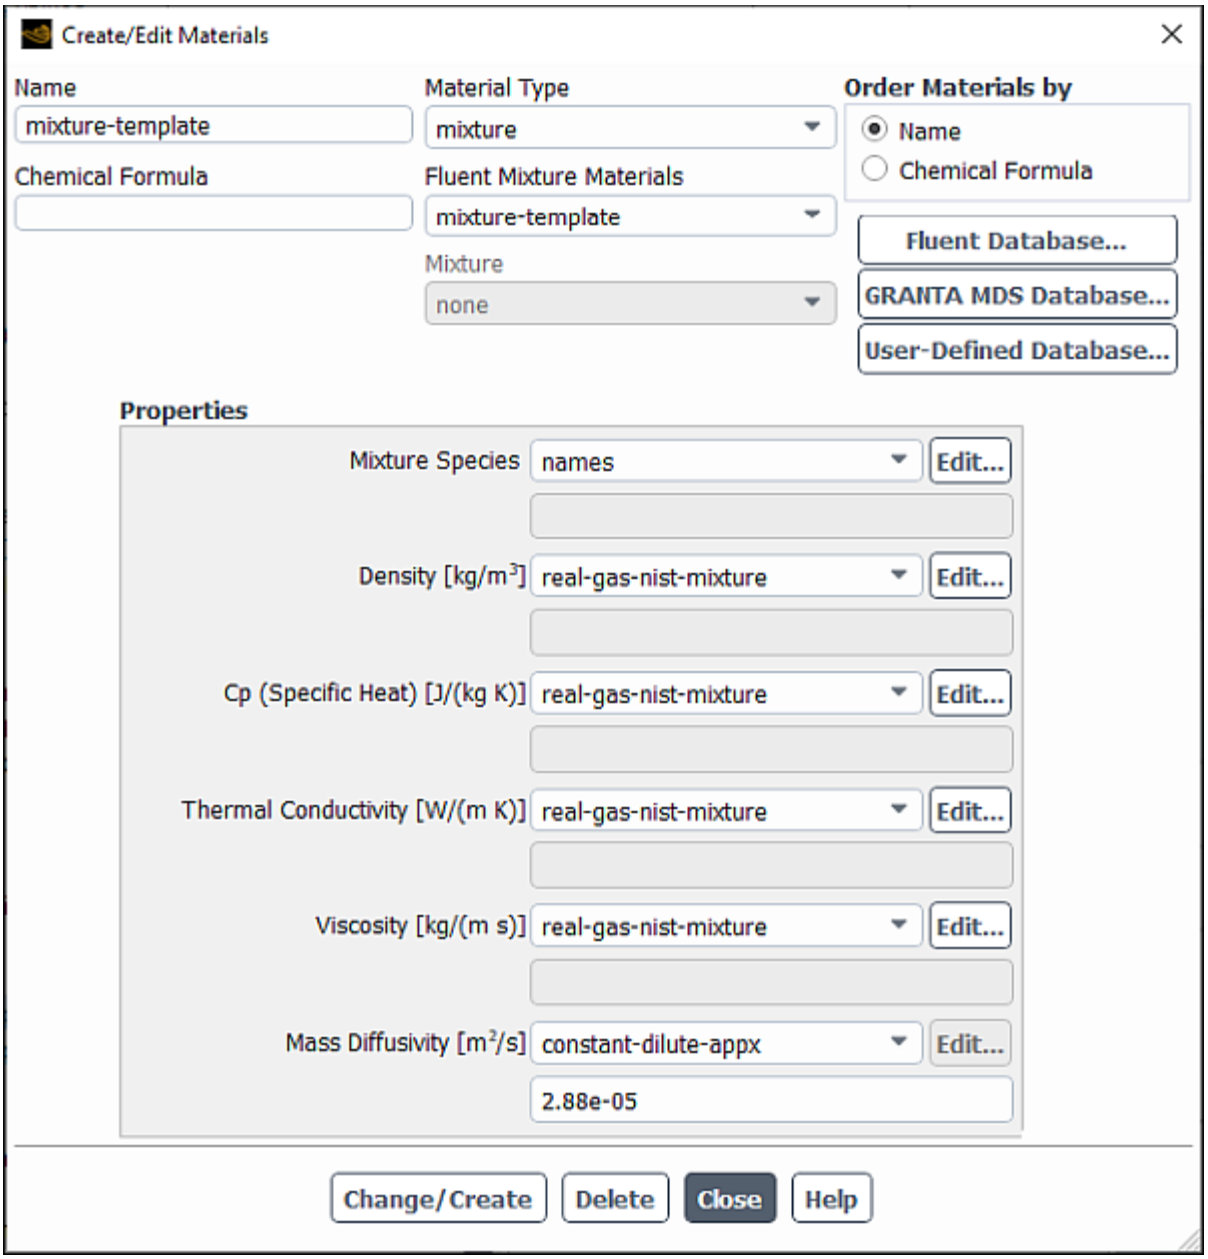
Figure 8.46: The NIST Fluid Data Dialog Box



For multiple-species mixtures, enable the **Species Transport** model and specify the number and names of species, as described in Enabling Species Transport and Reactions and Choosing the Mixture Material (p. 2357). Then on the **Create/Edit Materials** dialog box, select **real-gas-nist-mixture** for **Density**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 8.47: The Create/Edit Materials Dialog Box with NIST Mixture Model Enabled



Afterwards, you must select the appropriate NIST fluid data for each species as you would for a pure fluid.

Important:

- For mixture flows, not all combinations of species mixtures are allowed. This could be due to lack of data for one or more binary pairs. In such situations an error message generated by NIST will be returned and displayed on the Ansys Fluent console, and no real gas material is allowed to be created. In some combinations the mixing data will be estimated, a warning message will be displayed on the Ansys Fluent console and the mixture material allowed to be created.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

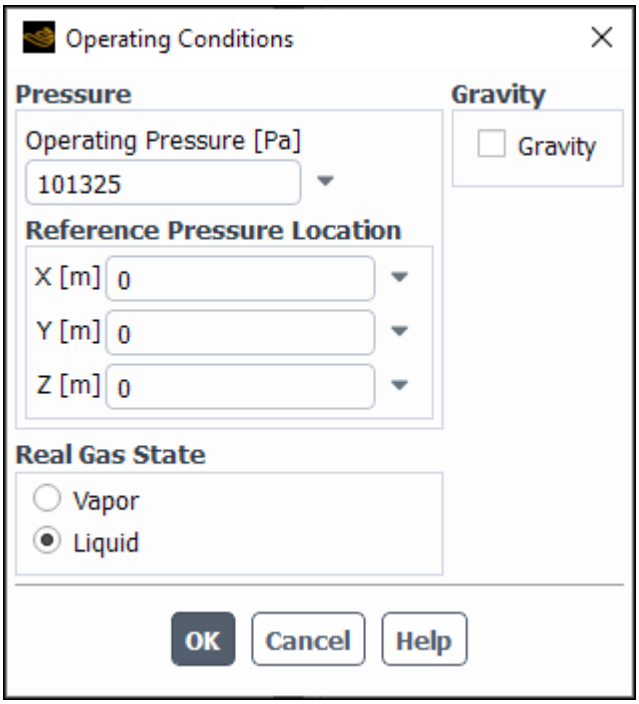
- Transport property calculations are not supported for mixtures that include water with molar concentration over 5%. If this limit is exceeded in your calculation, Ansys Fluent will issue a warning message. Transport equations are not available for the ammonia/water mixture and for mixtures with alcohols. As a result, the NIST real gas model with those mixtures can only be used for modeling inviscid flow.

Cp (Specific Heat), **Thermal Conductivity**, and **Viscosity** will be automatically set respectively to real-gas-nist (pure fluid) or real-gas-nist-mixture (multiple species mixture).

If you want to use NIST lookup tables in your simulation, you can create them as described in Creating NIST Look-up Tables (p. 1681).

If your case contains no NIST tables, and you would like to model flow in the liquid state, you can set the **Real Gas State** to liquid in the **Operating Conditions** dialog box.

Figure 8.48: Operating Conditions dialog Box with Liquid State Enabled



In addition, you may specify the state for specific fluid zones or a specific phase (if you are using the multiphase model) by typing the following text command in the Ansys Fluent console prompt:

```
> define boundary-conditions modify-zones change-zone-state
Select a name/id from fluid zones list [(liquid-zone fluid-1)] liquid-zone
Set zone real-gas state:
  -1:use global setting
  0:liquid
  1:vapor
[-1]  0
```

8.16.4.3.1. Creating NIST Look-up Tables

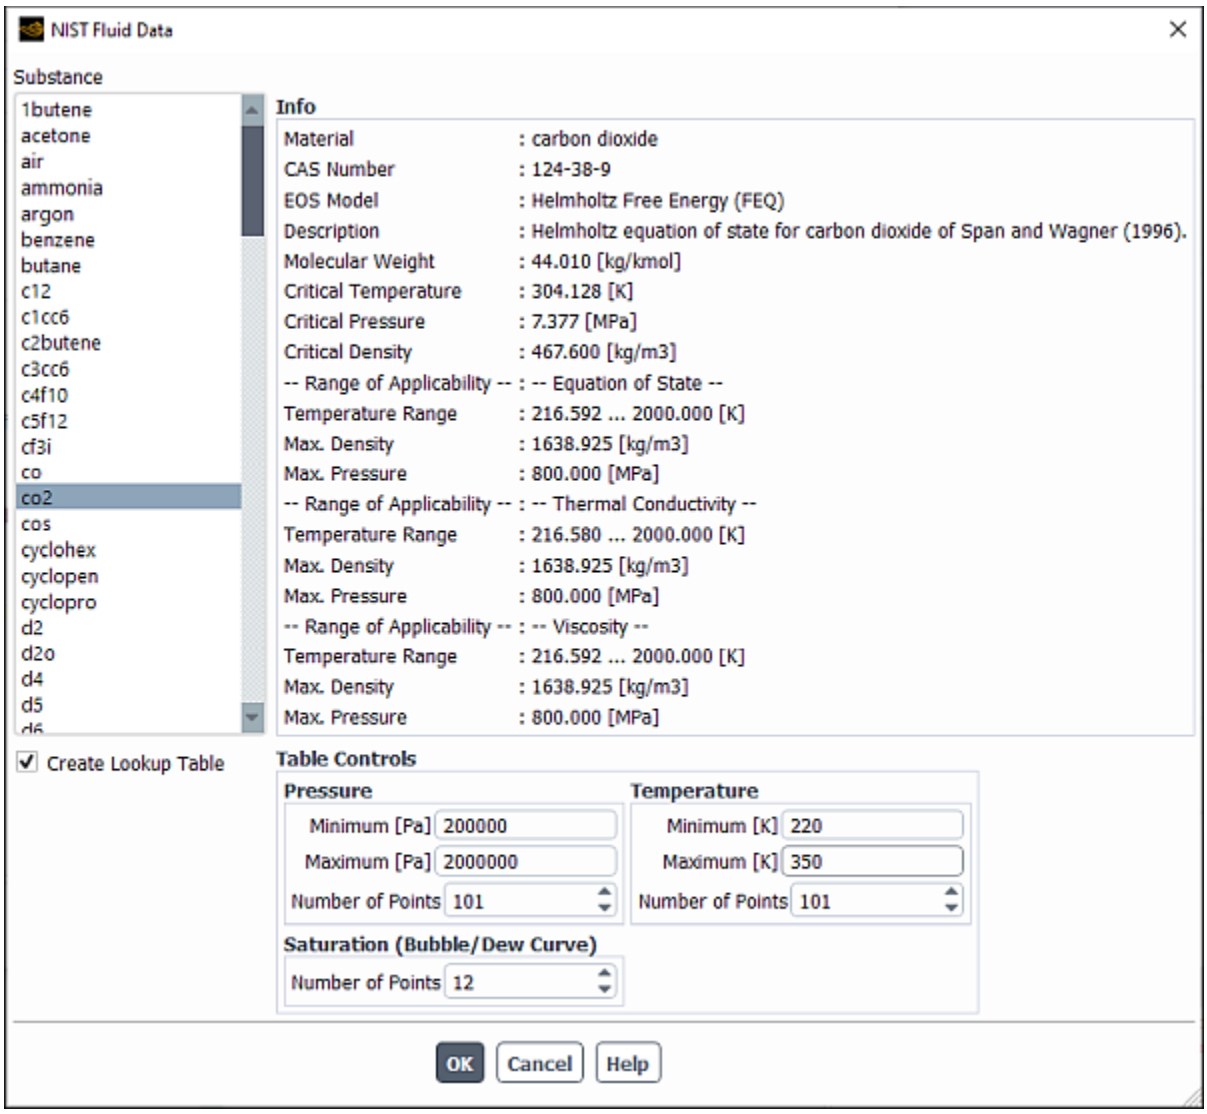
By default, the NIST functions are called directly each time the thermal properties are updated during an iteration. Alternatively, you can use NIST look-up tables in your simulation as described

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

below. Computing the look-up table reduces the computation time because the NIST functions do not need to be called each time the thermal properties are updated.

To create a full NIST look-up table, first enable the NIST real gas model as described in Using the NIST Real Gas Models (p. 1678), and then select **Create Lookup Table**.

Figure 8.49: The NIST Fluid Data Dialog Box With Lookup Table Enabled



For both single and multi-species real gas models, you need to specify:

- **Pressure** and **Temperature** bounds for the table.

  You must ensure that the temperature and pressure bounds you specify are strictly within the stated limits of applicability that are displayed when selecting the NIST fluid data.

- Number of pressure and temperature points.

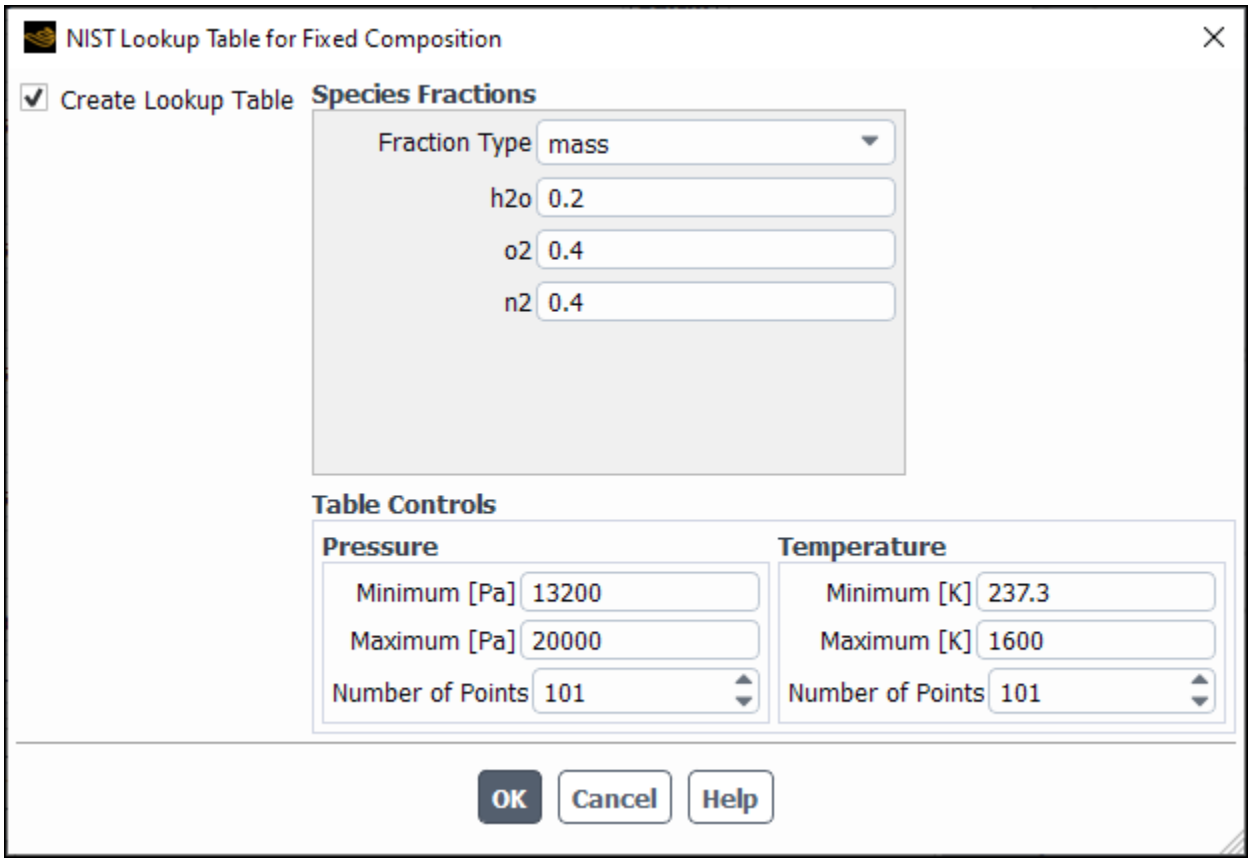
  The minimum number of pressure and temperature points is 12 and there is no upper limit. However, the larger the table, the greater the memory and computing time requirements. It is advised to perform test runs to balance the costs (memory and computing time) and accuracy.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For single-species, you also need to specify the number of points for **Saturation (Bubble/Dew Curve)** properties.

For multi-species, you also need to specify the mixture composition on a mass or mole basis. You must ensure that the sum of all constituent fractions add up to 1 when specifying mass/molar fractions for the components. The maximum number of species is 20.

Figure 8.50: The NIST Fluid Data Dialog Box For Fixed Composition



If properties are needed at conditions outside the limits you have specified for the table, Fluent automatically calls the original NIST model functions to calculate the thermal properties. If more than 10% of the property evaluations require computation outside the look-up table, Fluent prints a message indicating the percentage of calculations using direct computation. This can be used as an indicator to adjust the temperature and pressure ranges for the table to minimize the computational cost.

8.16.4.3.1.1. Capabilities and Limitations with NIST Look-up Tables

- For computation of saturation properties for the bubble and dew points for a single- or multiple-species, Fluent provides macros that you can use in UDFs. See NIST Real Gas Saturation Properties for more information.
- Look-up tables apply for compressible fluids with material properties that are a function of local pressure and temperature. The material properties covered by the table include fluids in the liquid and vapor phases. Flashing applications between liquid and vapor phases can be conducted using saturation conditions established for the fluid(s) using mass transfer models.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Look-up tables and saturation tables are created for fixed fluid compositions. This means the look-up tables are based on the following assumptions:
  - Mixture composition is constant.
  - No chemical reactions are involved.
  - No mixing of fluids of different compositions, including no mixing between phases.
- Look-up tables only apply to single-species/multi-species in single-phase flows
- The temperature and pressure bounds must be specified within the stated limits of applicability that are displayed when the NIST model is loaded.
- When specifying the look-up table size, it is important to pick temperature and pressure ranges that are large enough to satisfy the current flow conditions.
- If the temperature and pressure ranges you specify are too narrow, Fluent uses the NIST model to calculate thermal properties. The time saved by creating the table will be negated if the percentage of calculations performed outside of the table is greater than 10%. This percentage is printed, so you can use it as an indicator for adjusting the temperature and pressure range of the table.
- The look-up table is a structured table and may not be suitable for simulating flow behaviors near the critical point when higher resolution is required.

8.16.4.4. Legacy TUI for the NIST Real Gas Models

When you enable one of the NIST real gas models (pure fluid or multiple-species mixture) using the legacy TUI and select a valid material, Ansys Fluent's functionality remains the same as when you model fluid flow and heat transfer using an ideal gas, with the exception of the Create/Edit Materials Dialog Box (p. 4833).

8.16.4.4.1. Limitations of the Legacy TUI NIST Real Gas Models

When you enable one of the NIST real gas models (pure fluid or multiple-species mixture) through the legacy TUI, the following limitations apply in addition to those listed in Limitations of the NIST Real Gas Models (p. 1675):

- When you are using the NIST real gas models, the NIST materials defined in your simulation will appear in the Create/Edit Materials Dialog Box (p. 4833) either with the name **real-gas-*_name***, where ***_name*** is the NIST material selected for the single species model, or with the name **real-gas-mixture** for the multiple species model. The inputs for the properties calculated by the NIST functions are disabled. You can use the Create/Edit Materials Dialog Box (p. 4833) to define or modify:
  - Mass diffusivity property in the **real-gas-mixture** material if you are using the multiple-species NIST real gas model (note that the **kinetic-theory** option is not available)
  - Radiation properties if you are modeling radiation
  - Properties of materials other than the NIST **real-gas-mixture** or **real-gas-fluid** materials

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8.16.4.4.2. Activating the NIST Real Gas Model

Activating one of the NIST real gas models is a two-step process. First you enable either the single- or multi-species NIST real gas model, and then you select the fluid material from the REFPROP database.

1. Enable the appropriate NIST real gas model by typing the following text command at the Ansys Fluent console prompt:

   - Pure fluid real gas model:

     ```
     > define/user-defined/real-gas-models/nist-real-gas-model
     use NIST real gas? [no] yes
     ```

   - Multi-species real gas model:

     ```
     > define/user-defined/real-gas-models/nist-multispecies-real-gas-model
     use multispecies NIST real gas? [no] yes
     ```

   The list of available pure fluid materials you can select from will be displayed.

2. Select material from the REFPROP database list:

   - Pure fluid real gas model:

     Enter the name of a single pure fluid that you want to investigate as follows:

     ```
     select real-gas data file [""]  methane.fld
     ```

   - Multi-species real gas model:

     Enter the number of desired species in the mixture:

     ```
     Number of species []  3
     ```

     followed by the name of each fluid in quotation marks selected from the list printed in the console:

     ```
     select real-gas data file [""] nitrogen.fld
     select real-gas data file [""] co2.fld
     select real-gas data file [""] methane.fld
     ```

     a. Upon selection of a valid pure or multi-species fluids, Ansys Fluent will load the relevant material data from a library of pure fluids supported by the REFPROP database, and report that it is opening the shared library (`librealgas.so`) where the compiled REFPROP

database source code is located. A list of properties for the specified material, including its applicable pressure and temperature ranges, will also be reported in the console.

Important:

– For mixture flows, not all combinations of species mixtures are allowed. This could be due to lack of data for one or more binary pairs. In such situations an error message generated by NIST will be returned and displayed on the Ansys Fluent console, and no real gas material is allowed to be created. In some combinations the mixing data will be estimated, a warning message will be displayed on the Ansys Fluent console and the mixture material allowed to be created.

– Transport property calculations are not supported for mixtures that include water with molar concentration over 5%. If this limit is exceeded in your calculation, Ansys Fluent will issue a warning message. Transport equations are not available for the ammonia/water mixture and for mixtures with alcohols. As a result, the NIST real gas model with those mixtures can only be used for modeling inviscid flow.

3. If you want to use NIST lookup tables in your simulation, you can create them as described in the following sections:

   • Creating Full NIST Look-up Tables (p. 1686) (single and multi-species materials with thermal properties as well as saturation data for a fixed multi-species composition)

   • Creating Binary Mixture Saturation Tables for Binary Mixtures (p. 1689) (binary mixtures only)

4. (cases with no NIST tables only) If you would like to model flow in the liquid state, you can use the `set-state` TUI command. Note that the default state is vapor, so if you do not go through this step, vapor is assumed. Also, if the flow conditions do not permit liquid to exist, a vapor calculation will be performed instead.

```
 > define/user-defined/real-gas-models/set-state
Select vapor state (else liquid)?[yes]
```

   In addition, you may specify the state for a specific fluid zone or a specific phase (if you are using the multiphase model) by typing the following text command at the Ansys Fluent console prompt:

```
> define boundary-conditions modify-zones change-zone-state
Select a name/id from fluid zones list [(liquid-zone fluid-1)] liquid-zone
Set zone real-gas state:
  -1:use global setting
  0:liquid
  1:vapor
[-1]  0
```

8.16.4.4.3. Creating Full NIST Look-up Tables

By default, the NIST functions are called directly each time the thermal properties are updated during iteration. Alternatively, you can use the NIST look-up tables in your simulation as described below. Computing the look-up table offers two advantages:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Reduction in computation time because the NIST functions do not need to be called each time the thermal properties are updated
- The look-up table created is applicable to both liquid and vapor phases

To create a full NIST look-up table, first enable the NIST real gas model as described in Activating the NIST Real Gas Model (p. 1685), and then follow these steps:

1. When prompted with `Create Full NIST LookUp Tables for multi components? [no]`, answer **`yes`**.
2. Specify parameters for the look-up table generation.

   For both single- and multi-species real gas models, you need to specify:

   - Pressure and temperature bounds for the table

     You must ensure that the temperature and pressure bounds you specify are strictly within the stated limits of applicability that are displayed when the NIST model is loaded.

   - Number of pressure, temperature, and saturation points, which determines the resolution of the property look-up table

     The minimum number of pressure and temperature points is 12 and there is no upper limit. However, the larger the table, the greater the memory and computing time requirements. Use a few test runs to strike the best balance of costs (memory and computing time) and accuracy.

   For multi-species, you will also need to specify:

   - Upper and lower molar density bounds for bubble and dew point calculations

     Molar density is used to build the saturation table. The default values work well for most compositions.

   - The mixture composition on a mass or mole basis

     You must ensure that the sum of all constituent fractions adds up to 1 when specifying mass/molar fractions for the components. The maximum number of species is 20.

   - The bubble points and dew points filenames and the directory where you want to store the files.

   Examples of inputs for the NIST look-up tables:

   - Pure fluid real gas model:

```
Min Pressure Value For NIST Table (pa) [13200]
Max Pressure Value For NIST Table (pa) [20000] 1000000
Min Temperature Value For NIST Table (k) [237.3]
Max Temperature Value For NIST Table (k) [500] 400
Number of Pressure Points For NIST Table [101]
Number of Temperature Points For NIST Table [101]
Number of Saturation Points For Bubble/Dew Curve [300]

 NIST table created! Properties for both liquid and vapor phases included!
 Tcrit = 3.391730e+02 pcrit = 3.617700e+06 Dcrit = 5.735823e+02 Ttrp = 1.725200e+02
```

- Multi-species real gas model:

```
Min Pressure Value For NIST Table (pa) [130000]
Max Pressure Value For NIST Table (pa) [5000000]
Min Temperature Value For NIST Table (k) [220] 180
Max Temperature Value For NIST Table (k) [490] 600
Number of Pressure Points For NIST Table [101]
Number of Temperature Points For NIST Table [101]
Please Select Mass Fractions [Y] or Molar Fractions [N] for Composition of Fluid
 [yes]
Composition of Fluid will be set in Mass Fractions!
co2.fld [0.4]
methane.fld [0.4] 0.6
Create NIST Saturation Curves for the same multi components?
[no] y
Number of Saturation Points For Bubble/Dew Curve [300] 22
Min Molar Density For Bubble and Dew Points Calculations (mol/l) [0.1]
Max Molar Density For Bubble and Dew Points Calculations (mol/l) [25]
Bubble Points File Name ["Bubble_PT.xy"]
Dew Points File Name ["Dew_PT.xy"]
Directory to store Saturation Files [""]
Start NIST Look-Up Table Calculations ...

Property Table... 83.3 percent completed!

NIST table for 2-components created! Properties for both liquid and vapor phases included!
End NIST Look-Up Table Calculations
Use the created NIST Lookup Table for thermal property calculations? [no] y
```

Once the table is created, you must confirm that you want to use the look-up table for thermal properties calculations when prompted.

```
Use the created NIST Lookup Table for thermal property calculations? [no] yes

 The created NIST Lookup Table will be used to calculate the thermal properties!
```

If properties are needed at conditions outside the limits you have specified for the table, Fluent will automatically call the original NIST model functions to calculate the thermal properties. If more than 10% of the property evaluations require computation outside the look-up table, Fluent will print a message indicating the percentage of calculations using direct computation. This can be used as an indicator to adjust the temperature and pressure ranges for the table to minimize the computational cost.

For multi-species real gas properties, the following tables will be created:

- fluid properties
- saturation conditions

Capabilities and Limitations on Using Multi-Species Full NIST look-up Tables

- The look-up table is not saved with the case file. If you restart Fluent or re-read case and data files into the current Fluent session, the table will be cleared and you must go through the steps above to re-create it before running a simulation.
- For computation of saturation properties for the bubble and dew points for a single- or multiple-species, Fluent provides macros that you can use in UDFs. See NIST Real Gas Saturation Properties in the *Fluent Customization Manual* for more information.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The tables apply for compressible fluids with material properties that are a function of local pressure and temperature. The material properties covered by the table include fluids in the liquid and vapor phases. The flashing applications between liquid and vapor phases can be conducted using saturation conditions established for the fluid(s) using mass transfer models.
- The property look-up tables and saturation tables are created for fixed fluid compositions. This means the look-up tables are based on the following assumptions:
  - Mixture composition is constant
  - No chemical reactions are involved
  - No mixing of fluids of different compositions, including no mixing between phases
- The look-up table only applies to single-species/multi-species in single-phase flows.
- The temperature and pressure bounds must be specified within the stated limits of applicability that are displayed when the NIST model is loaded.
- When specifying the table size, it is important to pick temperature and pressure ranges that are large enough to satisfy the current flow conditions.
- If the temperature and pressure ranges you specify are too narrow, Fluent uses the NIST model to calculate the thermal properties. The time saved by creating the table will be negated if the percentage of calculations performed outside of the table is greater than 10%. This percentage is printed, so you can use it as an indicator for adjusting the temperature and pressure range of the table.
- For multi-species table, the bubble and dew points are saved into files(Fluent plot file format) called `Bubble_PT.xy` and `Dew_PT.xy` in the working directory.
- The look-up table is a structured table and may not be suitable for simulating flow behaviors near the critical point when higher resolution is required.

8.16.4.4.4. Creating Binary Mixture Saturation Tables for Binary Mixtures

To create a saturation data look-up table for binary species mixtures (mixtures of two species only), first enable the NIST real gas model as described in Activating the NIST Real Gas Model (p. 1685) and then follow these steps:

1. When prompted with `Create Full NIST LookUp Tables for multi components? [no]`, answer **no**.
2. When prompted with `Create Saturation Table For Binary Mixture Only? [no]`, answer **yes**.

Important:

Not all binary mixtures can be computed from the Fluent built-in NIST model. The allowed combination of materials is determined by the current database of NIST that can be found in `hmx.bnc` in the Ansys Fluent installation directory.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Specify parameters for the binary saturation data look-up table generation:

   - The number of saturation curves
   - The number of points for each saturation curve

     The default number is 12. The actual number of points for each bubble and dew curve may be different than specified because the NIST model may not yield valid computation results for every density point for a given mass fraction.

   - Upper and lower molar density bounds for bubble and dew point calculations

     The molar density is used to build the saturation table. You should provide reasonable values for the minimum and maximum molar densities corresponding to gas phase at low pressure and high temperature, and liquid phase at high pressure and low temperature. The default values (as shown in the example below) are a good starting point. You may need to adjust these values if there is not enough data in the selected range.

   - The filenames for bubble points and dew points and the existing directory where you want to store the files.

   An example of inputs for the NIST binary look-up table:

   ```
   Number of Mass Fraction Points For Binary Mixture [12]
   Number of Saturation Points For Bubble/Dew Curve [12]
   Min Molar Density For Bubble and Dew Points Calculations (mol/l) [0.1]
   Max Molar Density For Bubble and Dew Points Calculations (mol/l) [25]
   Bubble Points File Name ["Bubble_PT.xy"]
   Dew Points File Name ["Dew_PT.xy"]
   Directory to store Saturation Files [""] out
   ```

   The lookup table builds multiple sets of the bubble and dew points for the binary mixture with mass fractions for the first component between 0 and 1. The second component mass fraction is equal to the first component mass fraction subtracted from unity. The number of saturation curves is determined by the number of mass fraction points that you specified.

   Once the lookup table is created, Fluent saves the bubble and dew points data into files and directory you specified.

NIST Binary Saturation Files

NIST binary saturation files store saturation data lookup table for bubble and dew points for a binary mixture with mass fractions between 0 and 1. They can be used for mass and heat transfer modeling involving phase changes.

The binary saturation file structure is as follows. The file contains several data sets for bubble/dew point curves for a series of mass fractions. Each data set consists of the following three parts:

1. Line 1: The mass fraction of the first species (a single float number between 0 and 1).
2. Line 2: The number of data pairs for saturation pressure and temperature.
3. The specified number of lines that follow line 2: Data pairs of saturation pressure and temperature. The last pressure-temperature pair corresponds to the critical condition.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The example below shows the saturation dew point data for the first two curves, both with 12 pressure-temperature pairs. The first data set is for 0 and the second is for a 0.083333 mass fraction of the first species. The pressure-temperature critical condition is (4.872200e+06, 3.053220e+02) for the first curve and (5.547305e+06, 2.947561e+02) for the second curve.

8.16.4.4.5. Changing the REFPROP Library and Fluid Files

In Ansys Fluent, you can change the REFPROP library and the fluid files that are accessed by the NIST real-gas model by entering the following text command in the Ansys Fluent console:

`/define/user-defined/real-gas-models/nist-settings`

When prompted with

```
User-defined refprop library and fluids files?
```

answer **yes**.

The default names for the refprop library and the fluid file paths correspond to the REFPROP v9.1 files provided with your Ansys Fluent installation. You can revert to the older REFPROP v7.0.1 database by accepting the default refprop library path and entering the following names at the prompts for library name and fluid files path:

```
Select refprop library path ["path\fluent24.1.0\realgas"]
Select refprop library name[“librealgas”] “librealgas7”
Select refprop fluid files path ["path\fluent24.1.0\realgas\lib"] “path\fluent24.1.0\realgas\lib7.0”
```

where *path* is the Ansys Fluent installation directory (for example, `C:\Program Files\ANSYS Inc\v241\fluent`).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Ansys Fluent will open REFPROP v7.0 library and report the information in the console.

To switch back to the default REFPROP v9.1 property database, enter the `/define/user-defined/real-gas-models/nist-settings` command again and enter **no** at the prompt. Ansys Fluent will report the change in the console window.

8.16.4.5. Solution Strategies and Considerations for NIST Real Gas Model Simulation

The flow modeling of NIST real-gas flow is much more complex and challenging than simple ideal-gas flow. Therefore, you should expect the solution to converge at much slower rate with real-gas flow than when running ideal-gas flow. Also due to the complexity of the equations used in property evaluations, converging a solution with the real-gas model is in general done at much lower Courant values when you are using the density-based solver, or at much lower under-relaxation values if you are using the pressure-based solver. It is recommended that you first attempt to converge your solution using first-order discretization, then switch to second-order discretizations and re-iterate to convergence.

The real-gas properties in NIST are defined within a limited/bounded range. It is important that the flow conditions you are prescribing fall within the range of the database. It is possible that you specify flow at a state that is physically valid but otherwise not defined in the database. In this situation the solution will diverge or immediately generate an error message on the Ansys Fluent console as soon as the state crosses the limit of the database. In some instances, the actual converged state is just within the bounded defined database but only transitory outside the range. In this situation the divergence can be avoided by lowering the Courant value or under-relaxation factors so a less aggressive convergence rate is adapted.

Finally, if you attempt to initialize the flow from an inlet flow conditions and an error message is generated from one of the property routines, then this is an indicator that the flow conditions you have specified is not defined within the range of the database.

8.16.4.5.1. Writing Your Case File

When you save your completed real gas model to a case file, the linkage to the shared library containing real gas properties will be saved to the case file (along with property data for the material you selected in the NIST real gas model). This information can be reported to the console by listing the material properties (using the command `/define/materials/list-properties <material-name>`) and viewed in the **Create/Edit Materials** dialog box by selecting **Edit...** for density.

8.16.4.5.2. Postprocessing

All postprocessing functions properly report and display the current thermodynamic and transport properties of the selected real gas model. The thermodynamic and transport properties controlled by the NIST real gas model include the following:

- density
- enthalpy
- entropy

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- molecular weight
- molecular viscosity
- sound speed
- specific heat
- thermal conductivity In addition to the properties listed above, you can also report
- compressibility factor
- any quantities that are derived from the properties listed above (for example, total quantities, ratio of specific heats)

8.16.5. The User-Defined Real Gas Model

The user-defined real gas model (UDRGM) has been developed to allow you to write your own custom real gas model to fit your particular modeling needs. It also allows you to simulate a single-species flow, multiple-species mixture flow, multiphase flow, or volumetric reactions.

The following limitations exist for the UDRGM:

8.16.5.1. Limitations of the User-Defined Real Gas Model

- You cannot include more than one user-defined real gas material (fluid or mixture) in the same problem. However, you can use other materials together with real gas in your simulation.
- When you are using the UDRGM, the materials defined in your real gas UDF will appear in the Create/Edit Materials Dialog Box (p. 4833) with the name **real-gas-fluid** or **real-gas-mixture** and all physical and thermodynamic property inputs disabled. Use the Create/Edit Materials Dialog Box (p. 4833) to define or modify:
  - Mass diffusivity property in the real-gas-mixture material if you are modeling multicomponent flow.
  - Chemical reactions in the real-gas-mixture if you are modeling reacting flow.
  - Radiation properties for the real-gas-mixture or the real-gas-fluid materials if you are modeling radiation.
  - Properties of materials other than the user-defined **real-gas-mixture** or **real-gas-fluid** materials.

  Note:

  If you are using the UDRGM together with other materials from Ansys Fluent's property database in dispersed phase or multiphase calculations, take care to use the same reference temperature as in Ansys Fluent in your real-gas UDF. The reference temperature in Ansys Fluent is 298.15 K.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Pressure-inlets, mass flow-inlets, and pressure-outlets are the only inflow and outflow boundaries available for use with the real gas models.
- Non-reflecting boundary conditions are not compatible with the real gas models when using the density-based solver. If your model requires NRBC and a real gas model, you must use the pressure-based solver.
- The UDRGM can be used with the Eulerian multiphase models.
- The UDRGM is compatible with the Lagrangian Dispersed Phase Models. Refer to Using the Cubic Equation of State Models with the Lagrangian Dispersed Phase Models (p. 1672) for guidelines and restrictions of this approach.
- The real gas models cannot be used with the non-premixed, partially premixed, and composition PDF transport combustion models. Chemical reactions can however be modeled with the finite rate and eddy dissipation models. Note that the **Dimension Reduction** model is not available with the real gas models.
- The UDRGM does not allow specification of site or solid species and consequently cannot be used with wall surface reactions.

The UDRGM requires a library of functions written in the C programming language. Moreover, there are certain coding requirements that need to be followed when writing these functions. Sample real gas function libraries are provided to assist you in writing your own UDRGM. When UDRGM functions are compiled, they will be grouped in a shared library that later will be loaded and linked with the Ansys Fluent executable. The procedure for using the UDRGM is defined as follows:

1. Define the real gas equation of state and all related thermodynamic and transport property equations.
2. Create a C source code file that conforms to the format defined in this section.
3. Start Ansys Fluent and set up your case file in the usual way.
4. Compile your UDRGM C library and build a shared library file (you can use the available compiled UDF utilities in either the graphical user interface or the text command interface).
5. Load your newly created UDRGM library via the text command menu:

   If a single-species UDRGM to be used, then the text command menu is:

   ```
   > define/user-defined/real-gas-models/user-defined-real-gas-model

     use user defined real gas? [no] yes
   ```

   On the other hand, if you are simulating multiple-species UDRGM flow, then the text command menu to use is:

   ```
   > define/user-defined/real-gas-models/user-defined-multispecies-real-gas-model
     use user multispecies defined real gas? [no] yes
   ```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Upon activating the UDRGM, the function library will now supply the fluid material properties for your case.

6. You can simulate volumetric reactions with your real gas model using the Species Model Dialog Box (p. 4716), or the text interface (`define/models/species/volumetric-reactions?`).

   You can access the **Species Model** from the tree by going to **Setup**/**Models**/**Species** and double-clicking **Species**.

   In the Species Model Dialog Box (p. 4716)

   - Enable **Species Transport** under **Model**.
   - Enable **Volumetric** under **Reactions**.
   - Select the appropriate **Turbulence-Chemistry Interaction** option.
   - Set up the reaction by clicking the **Edit...** button for the **real-gas-mixture Mixture Material**.

   Important:

   Note that the fluid materials and their properties, appearing in the Create/Edit Materials Dialog Box (p. 4833), are the ones defined in your real gas UDF. You cannot modify the materials via this dialog box, however, you can set up the volumetric reaction. If you would like to modify the mixture materials and their properties, this should be done in the real gas UDF. The volumetric reactions for your real gas mixture are defined in the same way as for any Ansys Fluent mixture. For details, refer to Defining Reactions (p. 2377).

   Alternatively, the chemical reactions can be set up using the `define/models/species` and `define/materials` text command.

   Important:

   Note that the chemical reactions should be activated after your real gas UDF has been built and loaded. It is also recommended to test and validate your real gas UDF, running the cold flow calculation prior to attempting to solve the reacting flow. Also, make sure that the applicability range of the real gas functions in your UDF fully covers the temperature and pressure range of the reacting flow calculation.

7. Run your calculation.

When using the UDRGM the robustness of the solver and the speed of flow convergence will largely depend on the complexity of the material properties you have defined in your UDF. It is important to understand the operational range of the property functions you are coding so you can simulate the flow within that range.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8.16.5.2. Writing the UDRGM C Function Library

Creating a UDRGM C function library is reasonably straightforward; however, your code must make use of specific function names and macros, which will be described in detail below. The basic library requirements are as follows:

- The code must contain the `udf.h` file inclusion directive at the beginning of the source code. This allows the definitions for `DEFINE` macros and other Ansys Fluent functions to be accessible during the compilation process.
- The code must include at least one of the UDF's `DEFINE` functions (that is `DEFINE_ON_DEMAND`) to be able to use the compiled UDFs utility (see the sample UDRGM codes provided below).
- Any values that are passed to the solver by the UDRGM or returned by the solver to the UDRGM are assumed to be in SI units.
- You must use the principal set of functions listed below in your UDRGM library. These functions are the mechanism by which your thermodynamic property data are transferred to the Ansys Fluent solver. Note that `ANYNAME` can be any string of alphanumeric characters, and allows you to provide unique names to your library functions.

Function inputs from the Ansys Fluent solver consist of one or more of the following variables:

T = Temperature, K

p = Pressure, Pa

ρ = Density, kg/m^3

$Y_i[]$ = Species mass fraction

`cell` = Cell or face index, depending on whether the thread is a cell or face zone; `NULL_CELL` is passed when the function is called without a cell/face context

`thread` = Pointer to thread structure; `NULL` is passed when the function called without thread context

---

Important:

- $Y_i[]$: Ansys Fluent solver returns a value of `1.0` for $Y_i[]$ in single-species flows. For multiple-species flows, $Y_i[]$ is a vector array containing species mass fraction in an order defined by the user setup function.
- For temperature, density, pressure and species mass fractions the UDRGM code should use the values provided as functions arguments. The corresponding values in the solution arrays, which are accessible via cell index and thread pointer, may temporarily differ from these depending on algorithmic details, and the function arguments take precedence.

The UDRGM function names and argument lists, followed by a short description of the function, are as follows:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

void ANYNAME_Setup(Domain *domain, cxboolean vapor_phase, char *species_list, int (*messagefunc)(const char *format,...), void (*errorfunc)(const char *format, ...))

performs model setup and initialization. Can be used to read data and parameters related to your UDRGM. When writing UDFs for multiple-species, use this function to specify the number of species and the name of the species as shown in the multiple-species example. The Boolean variable, `vapor_phase`, passes to your UDF the setting of the text-interface command `define/user-defined/real-gas-models/set-state`.

The `messagefunc` argument is a function that you can use for including diagnostic output in the transcript file, and the `errorfunc` argument is the equivalent of error reporting. The format string and additional arguments follow the same syntax as the `printf` C function.

double ANYNAME_density(cell_t cell, Thread *thread, cxboolean vapor_phase, double T, double P, double yi[])

returns the value of density as a function of phase, temperature, pressure and species mass-fraction if applicable. The Boolean variable `vapor_phase` passes to your UDF the setting of the text-interface command `define/user-defined/real-gas-models/set-state`, or, if applicable, the zone state set by the text-interface command `define/boundary-conditions/modify-zones/change-zone-state`.

Important:

Since this function is called numerous times during each solver iteration, it is important to make this function as numerically efficient as possible.

---

double ANYNAME_specific_heat(cell_t cell, Thread *thread, double T, double Rho, double P, double yi[])

returns the real gas specific heat at constant pressure as a function of temperature, density, absolute pressure, and species mass-fraction if applicable.

double ANYNAME_enthalpy(cell_t cell, Thread *thread, double T, double Rho, double P, double yi[])

returns the enthalpy as a function of temperature, density, absolute pressure, and species mass-fraction if applicable.

double ANYNAME_entropy(cell_t cell, Thread *thread, double T, double Rho, double P, double yi[])

returns the entropy as a function of temperature, density, absolute pressure, and species mass-fraction if applicable.

double ANYNAME_mw(double yi[])

returns the fluid molecular weight.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

double ANYNAME_speed_of_sound(cell_t cell, Thread *thread, double T, double Rho, double P, double yi[])

returns the value of speed of sound as a function of temperature, density, absolute pressure, and species mass-fraction if applicable.

double ANYNAME_viscosity(cell_t cell, Thread *thread, double T, double Rho, double P, double yi[])

returns the value of dynamic viscosity as a function of temperature, density, absolute pressure, and species mass-fraction if applicable.

double ANYNAME_thermal_conductivity(cell_t cell, Thread *thread, double T, double Rho, double P, double yi[])

returns the value of thermal conductivity as a function of temperature, density, absolute pressure, and species mass-fraction if applicable.

double ANYNAME_rho_t(cell_t cell, Thread *thread, double T, double Rho, double P, double yi[])

returns the value of $\frac{d\rho}{dT}$ at constant pressure as a function of temperature, density, absolute pressure, and species mass-fraction if applicable.

double ANYNAME_rho_p(cell_t cell, Thread *thread, double T, double Rho, double P, double yi[])

returns the value of $\frac{d\rho}{dp}$ at constant temperature as a function of temperature, density, absolute pressure, and species mass-fraction if applicable.

double ANYNAME_enthalpy_t(cell_t cell, Thread *thread, double T, double Rho, double P, double yi[])

returns the value of $\frac{dh}{dT}$ at constant pressure as a function of temperature, density, absolute pressure, and species mass-fraction if applicable. Note that by definition $dh/\ dt==c_p$, so this function should simply return the specific heat value.

double ANYNAME_enthalpy_p(cell_t cell, Thread *thread, double T, double Rho, double P, double yi[])

returns the value of $\frac{dh}{dp}$ at constant temperature as a function of temperature, density, absolute pressure, and species mass-fraction if applicable.

double ANYNAME_enthalpy_prime(cell_t cell, Thread *thread, double T, double Rho, double P, double yi[], double hi[])

returns the value of the mixture enthalpy as a function of temperature, density, absolute pressure, and species mass fraction. In addition, your UDF must set the elements of the double array `hi[]` to the enthalpy of each species, in the same order as they are referenced in the mass fraction array `yi[]`. Note that the enthalpy in the function `enthalpy_prime` is defined as the sum of sensible enthalpy plus species formation enthalpy, and you should make sure that

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

its computation is consistent with the sensible enthalpy function ANYNAME_enthalpy. The function ANYNAME_enthalpy_prime is required for the calculation of the heat of reactions, if chemical reactions are being simulated. If you are not solving reacting flows, the function ANYNAME_enthalpy_prime can simply be omitted.

At the end of the code you must define a structure of type RGAS_Function whose members are pointers to the principal functions listed above. The structure is of type RGAS_Function and its name is RealGasFunctionList.

Important:

It is imperative that the sequence of function pointers shown below be followed. Otherwise, your real gas model will not load properly into the Ansys Fluent code.

```
UDF_EXPORT RGAS_Functions RealGasFunctionList =
{
 ANYNAME_Setup,                   /* Setup initialize */
 ANYNAME_density,                 /* density */
 ANYNAME_enthalpy,                /* sensible enthalpy */
 ANYNAME_entropy,                 /* entropy */
 ANYNAME_specific_heat,           /* specific_heat */
 ANYNAME_mw,                      /* molecular_weight */
 ANYNAME_speed_of_sound,          /* speed_of_sound */
 ANYNAME_viscosity,               /* viscosity */
 ANYNAME_thermal_conductivity,    /* thermal_conductivity */
 ANYNAME_rho_t,                   /* drho/dT |const p */
 ANYNAME_rho_p,                   /* drho/dp |const T */
 ANYNAME_enthalpy_t,              /* dh/dT |const p */
 ANYNAME_enthalpy_p               /* dh/dp |const T */
 ANYNAME_enthalpy_prime           /* enthalpy */
};
```

If volumetric reactions are not being simulated, then the function ANYNAME_enthalpy_prime can be removed or ignored from the RealGasFunctionList structure described here.

The principal set of functions described are the only functions in the UDRGM that will be interacting directly with the Ansys Fluent code. In many cases, your model may require further functions that will be called from the principal function set. For example, when multiple-species real gas model UDFs are written, the principal functions will return the mixture thermodynamic properties based on some specified mixing-law. Therefore, you may want to add further functions that will return the thermodynamic properties for the individual species. These auxiliary functions will be called from the principal set of functions. See User-Defined Real Gas Models (UDRGM) in the Fluent Customization Manual for examples that clearly illustrate this strategy.

8.16.5.3. Compiling Your UDRGM C Functions and Building a Shared Library File

This section presents the steps you must follow to compile your UDRGM C code and build a shared library file. This process requires the use of a C compiler. For more details on compiler requirements, see Compilers in the *Fluent Customization Manual*. To use the UDRGM you must first build the UDRGM library by compiling your UDRGM C code and then load the library into the Ansys Fluent code. The UDRGM shared library is built in the same way that the Ansys Fluent executable itself is built. Internally, a script called Makefile is used to invoke the system C compiler to build an object code library that contains the native machine language translation of your higher-level C source code. This shared library is then loaded into Ansys Fluent (either at run time or automatically when a case file is read) by a process called *dynamic loading*. The object libraries are specific to the

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

computer architecture being used, as well as to the particular version of the Ansys Fluent executable being run. The libraries must, therefore, be rebuilt any time Ansys Fluent is upgraded, when the computer's operating system level changes, or when the job is run on a different type of computer. The general procedure for compiling UDRGM C code is as follows:

- Place the UDRGM C code in the folder, that is, where your case file resides.
- Launch Ansys Fluent.
- Read your case file into Ansys Fluent.
- You can now compile your UDRGM C code and build a shared library file using either the graphical interface or the text command interface.

Important:

To build UDRGM library you will use the compiled UDF utilities. However, you will not use the UDF utilities to load the library. A separate loading area for the UDRGM library will be used.

8.16.5.3.1. Compiling the UDRGM Using the Graphical Interface

If the build is successful, then the compiled library will be placed in the appropriate architecture folder (for example, `win64/2d`). By default the library name is `libudf.so` (`libudf.dll` on Windows).

More information on compiled UDFs and building libraries using the Ansys Fluent graphical user interface can be found in the Fluent Customization Manual.

8.16.5.3.2. Compiling the UDRGM Using the Text Interface

The UDRGM library can be compiled in the text command interface as follows:

- Select the menu item `define` → `user-defined` → `compiled-functions` .
- Select the `compile` option.
- Enter the compiled UDF library name.

  Important:

  The name given here is the name of the folder where the shared library (for example, `libudf`) will reside. For example, if you press **Enter** then a folder should exist with the name `libudf`, and this folder will contain a library file called `libudf`. If, however, you type a new library name such as `myrealgas`, then a folder called `myrealgas` will be created and it will contain the library `libudf`.

- Continue on with the procedure when prompted.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Enter the C source file names.

  Important:

  Ideally you should place all of your functions into a single file. However, you can split them into separate files if desired.

- Enter the header file names, if applicable. If you do not have an extra header file then press **Enter** when prompted.

Ansys Fluent will then start compiling the UDRGM C code and put it in the appropriate architecture folder.

Example:

```
> define/user-defined/compiled-functions
  load OR compile ? [load]  compile

  Compiled UDF library name: ["libudf"] my_lib

   Make sure that UDF source files are in the folder
   that contains your case and data files. If you have
   an existing libudf folder, please remove this
   folder to ensure that latest files are used.
  Continue?[yes] RETURN

  Give C-Source file names:
  First file name: [""] my_c_file.c RETURN

  Next file name: [""] RETURN

  Give header file names:
  First file name: [""] my_header_file.h RETURN
```

8.16.5.3.3. Loading the UDRGM Shared Library File

Load the UDRGM library:

- Go to the following menu item in the text command interface.

  `define` → `user-defined` → `real-gas-models`

- Select one of the following

  – `user-defined-real-gas-model` if you are modeling a single-species real gas fluid

  – `user-defined-multispecies-real-gas-model` if you are modeling a multiple-species fluid-mixture

- Turn on the real gas model.

  – For single-species:

  ```
  use user defined real gas? [no]   yes
  ```

– For multiple-species:

```
use multispecies user defined real gas? [no]   yes
```

Ansys Fluent will ask for the location of the user-defined real gas library. You can enter either the name of the folder where the UDRGM shared library is called or the entire path to the UDRGM shared library.

If the loading of the UDRGM library is successful you will see a message similar to the following:

```
Opening user-defined realgas library "RealgasLibraryname"...
Library "RealgasDirName/lnamd64/2d/libudf.so" opened
Setting material "air" to a real-gas...
Loading Real-RealGasPrefexLable Library:
```

8.16.5.4. UDRGM Example: Ideal Gas Equation of State

This section describes an example of a user-defined real gas model. You can use this example as the basis for your own UDRGM code. In this simple example, the standard ideal gas equation of state is used in the UDRGM. See User-Defined Real Gas Models (UDRGM) in the Fluent Customization Manual for more examples of UDRGM functions, including multi-species real gas and reacting real-gas examples.

p = pressure

T = temperature

C_p = specific heat

H = enthalpy

S = entropy

ρ = density

c = speed of sound

R = universal gas constant/molecular weight

The ideal gas equation of state can be written in terms of pressure and temperature as

$$\rho=\frac{p}{RT} \tag{8.106}$$

The specific heat is defined to be constant C_p = 1006.42.

The enthalpy is, therefore, defined as

$$H=C_pT \tag{8.107}$$

and entropy is given by

$$S=C_p\log\left(\frac{T}{T_{ref}}\right)+R\log\left(\frac{p_{ref}}{p}\right) \tag{8.108}$$

where T_{ref} = 288.15 K and p_{ref} = 101325 Pa

The speed of sound is simply defined as

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$c=\sqrt{TC_p\frac{R}{\left(C_p-R\right)}} \tag{8.109}$$

The density derivatives are:

$$\left(\frac{d\rho}{dp}\right)_T=\frac{1}{RT} \tag{8.110}$$

$$\left(\frac{d\rho}{dT}\right)_p=-\frac{p}{RT^2}=-\frac{\rho}{T} \tag{8.111}$$

The enthalpy derivatives are:

$$\left(\frac{dH}{dT}\right)_p=C_p \tag{8.112}$$

$$\left(\frac{dH}{dp}\right)_T=\frac{C_p}{\rho R}\left[1-\frac{p}{\rho}\frac{d\rho}{dp}\right]=0 \tag{8.113}$$

When you enable the real gas model and load the library successfully into Ansys Fluent, you will be using the equation of state and other fluid properties from this library rather than the one built into the Ansys Fluent code.

8.16.5.5. Additional UDRGM Examples

You can find the following additional UDRGM examples in the Fluent Customization Manual:

- The Aungier Redlich Kwong equation of state for single component flow. See UDRGM Example: Redlich-Kwong Equation of State in the Fluent Customization Manual for details.
- A simple example of a multi-species real-gas model. See UDRGM Example: Multiple-Species Real Gas Model in the Fluent Customization Manual for details.
- A real gas model example with the Aungier Redlich Kwong equation of state, ideal gas mixing rules and volumetric reactions. See UDRGM Example: Real Gas Model with Volumetric Reactions in the Fluent Customization Manual for details.

8.16.6. Using Real Gas Property (RGP) Table Files

8.16.6.1. Overview

Real Gas Property (RGP) tables provide thermodynamic and transport material properties as functions of temperature and pressure. The material is modeled as a real-fluid equivalent of the cubic equations of state or NIST real gas models. For sub-critical conditions, the RGP tables may contain data for

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the liquid of vapor state, or both. RGP files often include data tables for both liquid and vapor physical states.

In `.rgp` files, the material property values are provided in tabular format as functions of temperature and pressure. As opposed to user-defined functions (UDFs), which are executed at solver run-time, when RGP tables are used, the potentially expensive property calculations are carried out in a pre-processing step, where you can deal with possible errors that may occur in property calculation. During the solution, the solver obtains material properties by table lookup, which is a computationally very efficient operation.

RGP table files support two-dimensional tables for material properties as functions of temperature and pressure.

8.16.6.2. Defining Material Properties Using RGP Tables

To import RGP tables into your simulation and use them for material property definition, follow these steps:

1. Read the RGP tables into your session as described in Reading Files in Tabular Format (p. 944).

   Upon importing the RGP file, table data set for each material contained in the file is automatically derived using the access key. The names of all RGB data sets appear in the **Tables** selection list in the **Table File Manage**r dialog box.

2. If necessary, create materials for which you want to use the RGP table data by doing one of the following:

   - Create a material for each RGP table data set using the **Table Settings** dialog box:

     i. In the **Table File Manager** dialog box, select the name of the RGP table data set for which you want to create a material and click the **Settings...** button.

     ii. In the **Table Settings** dialog box that opens, select **Create/update RGP material**.

     Figure 8.51: The Table Settings Dialog Box

     
     iii. Click **OK** to close the **Table Settings** dialog box.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

A material with the same name as the RGP table data set is created or updated if already exists. This material is automatically set to use the RGP tables for all properties available from the RGP data.

iv. Repeat these steps for all RGP table data sets that you want to use in your simulation.

- Create the material in the usual way.

3. If you want to embed the RGP data for the selected material set into your case file that you can read back into a later session of Ansys Fluent, select **Store in case file** in the **Table Settings** dialog box. This allows sharing the case without the need to provide the RGP data in a separate file at the expense of increased case file size.

4. Click **OK** to close the **Table File Manager** dialog box.

5. In the **Create/Edit Materials** dialog box, select the **rgp-table** option from the drop-down list for **Density** and then click **Edit...** to select the appropriate RGP table in the **RGP Table Data Set** dialog box. **Cp (Specific Heat)**, **Thermal Conductivity** and **Viscosity** will be automatically set to the **rgp-table** option using the RGP table data set selected for **Density**.

8.16.6.3. Defining Saturation Properties via RGP Tables

You can use RGP tables to specify the following saturation properties:

- Cavitation model: **Vaporization Pressure**
- Evaporation-condensation model: **Saturation Temperature**
- Boiling model: **Saturation Temperature**
- Species-mass-transfer model, Raoult's law: **Saturation Pressure**
- Phase Interaction Forces: **Surface Tension Coefficient** (using temperature-dependent values at saturation conditions)
- Droplet/Particle evaporation (DPM): **Saturation Vapor Pressure**

To do this:

1. Read the RGP table into your case as described in section Reading Files in Tabular Format (p. 944).

2. In the dialog box for the selected model, select **rgp-table-sat** from the drop-down list for the appropriate saturation property.

3. In the **RGP Table Saturation Data** dialog box that opens, select the desired saturation table and click **OK**.

Chapter 9: Modeling Basic Fluid Flow

This chapter describes the basic physical models that Ansys Fluent provides for fluid flow and the commands for defining and using them. Models for flows in moving zones (including sliding and dynamic meshes) are explained in Modeling Flows with Moving Reference Frames (p. 1741), models for turbulence are described in Modeling Turbulence (p. 2025), and models for heat transfer (including radiation) are presented in Modeling Thermal Energy (p. 2127). An overview of modeling species transport and reacting flows is provided in Modeling Species Transport and Finite-Rate Chemistry (p. 2353), details about models for species transport and reacting flows are described in Modeling Species Transport and Finite-Rate Chemistry (p. 2353) – Modeling a Composition PDF Transport Problem (p. 2440), and models for pollutant formation are presented in Modeling Pollutant Formation (p. 2583). The discrete phase model is described in Modeling Discrete Phase (p. 2669), general multiphase models are described in Modeling Multiphase Flows (p. 2911), and the melting and solidification model is described in Modeling Solidification and Melting (p. 3211). For information on modeling porous media, porous jumps, and lumped parameter fans and radiators, see Cell Zone and Boundary Conditions (p. 1277).

The information in this chapter is presented in the following sections:

9.1. User-Defined Scalar (UDS) Transport Equations

9.2. Periodic Flows

9.3. Swirling and Rotating Flows

9.4. Compressible Flows

9.5. Inviscid Flows

9.1. User-Defined Scalar (UDS) Transport Equations

For additional information, see the following sections:

9.1.1. Introduction

9.1.2. UDS Theory

9.1.3. Setting Up UDS Equations in Ansys Fluent

9.1.1. Introduction

Ansys Fluent can solve the transport equation for an arbitrary, user-defined scalar (UDS) in the same way that it solves the transport equation for a scalar such as species mass fraction. Extra scalar transport equations may be needed in certain types of combustion applications or for example in plasma-enhanced surface reaction modeling. Ansys Fluent allows you to define additional scalar transport equations in your model in the User-Defined Scalars Dialog Box (p. 5596).

9.1.2. UDS Theory

UDS theory is described in the following sections:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

9.1.2.1. Single Phase Flow
9.1.2.2. Multiphase Flow

9.1.2.1. Single Phase Flow

For an arbitrary scalar ϕ_k, Ansys Fluent solves the equation

$$\frac{\partial \rho \phi_k}{\partial t} + \frac{\partial}{\partial x_i}\left(\rho u_i \phi_k - \Gamma_k \frac{\partial \phi_k}{\partial x_i}\right) = S_{\phi_k} \quad k = 1, \ldots, N \tag{9.1}$$

where Γ_k and S_{ϕ_k} are the diffusion coefficient and source term supplied by you for each of the N scalar equations. Note that Γ_k is defined as a tensor in the case of anisotropic diffusivity. The diffusion term is therefore $\nabla \cdot \left(\Gamma_k \cdot \phi_k\right)$

For isotropic diffusivity, Γ_k could be written as $\Gamma_k I$ where I is the identity matrix.

For the steady-state case, Ansys Fluent will solve one of the three following equations, depending on the method used to compute the convective flux:

- If convective flux is *not* to be computed, Ansys Fluent will solve the equation

$$-\frac{\partial}{\partial x_i}\left(\Gamma_k \frac{\partial \phi_k}{\partial x_i}\right) = S_{\phi_k} \quad k = 1, \ldots, N \tag{9.2}$$

  where Γ_k and S_{ϕ_k} are the diffusion coefficient and source term supplied by you for each of the N scalar equations.

- If convective flux is to be computed with mass flow rate, Ansys Fluent will solve the equation

$$\frac{\partial}{\partial x_i}\left(\rho u_i \phi_k - \Gamma_k \frac{\partial \phi_k}{\partial x_i}\right) = S_{\phi_k} \quad k = 1, \ldots, N \tag{9.3}$$

- It is also possible to specify a user-defined function to be used in the computation of convective flux. In this case, the user-defined mass flux is assumed to be of the form

$$F = \int_S \rho \vec{u} \cdot d\vec{S} \tag{9.4}$$

where $d\vec{S}$ is the face vector area.

Important:

User-defined scalars in solid zones do not take into account the convective term with moving reference frames.

9.1.2.2. Multiphase Flow

For multiphase flows, Ansys Fluent solves transport equations for two types of scalars: *per phase* and *mixture*. For an arbitrary k scalar in *phase-l*, denoted by ϕ_l^k, Ansys Fluent solves the transport equation inside the volume occupied by *phase-l*

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\frac{\partial \alpha_l \rho_l \phi_l^k}{\partial t} + \nabla \cdot \left(\alpha_l \rho_l \vec{u}_l \phi_l^k - \alpha_l \Gamma_l^k \nabla \phi_l^k \right) = S_l^k \; k = 1, \ldots, N \tag{9.5}$$

where α_l, ρ_l, and $\vec{u}_l$ are the volume fraction, physical density, and velocity of *phase-l*, respectively. Γ_l^k and S_l^k are the diffusion coefficient and source term, respectively, which you will need to specify. In this case, scalar ϕ_l^k is associated only with one phase (*phase-l*) and is considered an individual field variable of *phase-l*.

The mass flux for *phase-l* is defined as

$$F_l = \int_S \alpha_l \rho_l \vec{u}_l \cdot d\vec{S} \tag{9.6}$$

If the transport variable described by scalar ϕ_l^k represents the physical field that is shared between phases, or is considered the same for each phase, then you should consider this scalar as being associated with a mixture of phases, ϕ^k. In this case, the generic transport equation for the scalar is

$$\frac{\partial \rho_m \phi^k}{\partial t} + \nabla \cdot \left(\rho_m \vec{u}_m \phi^k - \Gamma_m^k \nabla \phi^k \right) = S^{k_m} \; k = 1, \ldots, N \tag{9.7}$$

where mixture density ρ_m, mixture velocity $\vec{u}_m$, and mixture diffusivity for the scalar k Γ_m^k are calculated according to

$$\rho_m = \sum_l \alpha_l \rho_l \tag{9.8}$$

$$\rho_m \vec{u}_m = \sum_l \alpha_l \rho_l \vec{u}_l \tag{9.9}$$

$$F_m = \int_S \rho_m \vec{u}_m \cdot d\vec{S} \tag{9.10}$$

$$\Gamma_m^k = \sum_l \alpha_l \Gamma_l^k \tag{9.11}$$

$$S_m^k = \sum_l S_l^k \tag{9.12}$$

To calculate mixture diffusivity, you must specify individual diffusivities for each material associated with individual phases.

Note that if the user-defined mass flux option is activated, then mass fluxes shown in Equation 9.6 (p. 1711) and Equation 9.10 (p. 1711) must be replaced in the corresponding scalar transport equations. For more information about the theoretical background of user-defined scalar transport equations, see User-Defined Scalar (UDS) Transport Equations in the Theory Guide.

9.1.3. Setting Up UDS Equations in Ansys Fluent

Ansys Fluent allows you to define up to 50 user-defined scalar (UDS) transport equations in your model. The general scalar transport equation, Equation 1.8 in the Theory Guide, is shown below with

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the four terms (transient, flux, diffusivity, source) that you can customize. (Equation 9.13 (p. 1712)). You will define a UDS transport equation by setting the parameters for these four terms.

$$\underbrace{\frac{\partial \rho \phi_k}{\partial t}}_{unsteady} + \frac{\partial}{\partial x_i}\left(\underbrace{F_i \phi_k}_{convection} - \Gamma_k \underbrace{\frac{\partial \phi_k}{\partial x_i}}_{diffusion}\right) = \underbrace{S_{\phi_k}}_{sources} \qquad k=1,\ldots,N_{scalars} \tag{9.13}$$

In addition, you can set boundary conditions for the variables within cells of a fluid or solid zone for a particular scalar equation. This is done by fixing the value of ϕ_k in Equation 9.13 (p. 1712). When ϕ_k is fixed in a given cell, the UDS scalar transport is not solved and the cell is not included when the residual sum is computed. Additionally, you can also specify custom boundary conditions in the mixture on all wall, inflow, and outflow boundaries on a per-scalar basis.

The procedures for setting up a user-defined scalar (UDS) equation for single-phase and multiphase flows are outlined below. Note that a significant difference between a UDS for a single-phase versus a multiphase application is that you must associate each UDS with its corresponding phase domain or mixture domain, depending on your application. If you supply UDFs for transient terms, convective fluxes, and sources, you must be aware that they are directly called from the phase or mixture domains, according to the scalar association settings.

When setting up a UDS, ensure that the scalar transport problem is well defined with proper Dirichlet/Neumann boundary conditions. Depending on the nature of the problem, the UDS equation may need to converge further than the default convergence criterion of 0.1. Set the convergence criterion according to your needs.

In some instances, the residuals may not reflect the quality of the solution. In these cases you should create monitors on the UDS and use these monitors to judge solution convergence. There are several controls that you can adjust to improve convergence, however some of these adjustments can increase the computation time. The following controls can help with convergence:

- Using a fixed cycle, such as **F-Cycle** in place of **Flexible** cycle in the **Advanced Solution Controls** dialog box.
- Using an additional stabilizer such as the Biconjugate gradient stabilization method.
- Using an ILU smoother.
- Increasing the pre- and post-sweeps available in the **Advanced Solution Controls** dialog box.
- Adjusting the under relaxation factors.

See the Fluent Customization Manual for information on using UDFs to define scalar quantities.

9.1.3.1. Single Phase Flow

1. Specify the number of UDS equations you require in the User-Defined Scalars Dialog Box (p. 5596) (Figure 9.1: The User-Defined Scalars Dialog Box (p. 1713)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Parameters & Customization → User Defined Scalars New...

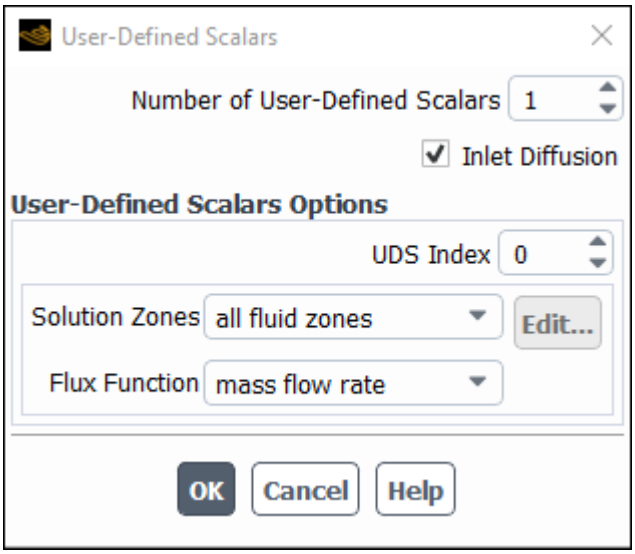
Important:

The maximum number of user-defined scalar transport equations you can define is 50. Ansys Fluent assigns numbers to the equations starting with 0.

Important:

Note that Ansys Fluent assigns a default name for each scalar equation (`User Scalar 0`, `User Scalar 1`, and so on). These labels will appear in graphics dialog boxes in Ansys Fluent. You can change them by means of a UDF. See the Fluent Customization Manual for details.

Figure 9.1: The User-Defined Scalars Dialog Box



2. Enable **Inlet Diffusion** if you want to include the diffusion term in the UDS transport equation for all inflow and outflow boundaries.

3. Set the first user-defined scalar equation parameters by making sure that the **UDS Index** is set to 0.

   a. Specify the **Solution Zones** you want the scalar equation to be solved in as **all fluid zones**, **all solid zones**, **all zones** (fluid and solid) or **selected zones**. If you choose **selected zones**, click the **Edit** button to view the list of zones you can select.

   b. Specify the **Flux Function** to be **none**, **mass flow rate**, or a user-defined function (UDF). The **Flux Function** determines how the convective flux is computed, which determines the equation that Ansys Fluent solves for the user-defined scalar. Selecting **none**, **mass flow rate**, or a user-defined function results in Ansys Fluent solving Equation 1.9, Equation 1.10, or Equation 1.11, respectively (in the Theory Guide). See the Fluent Customization Manual for details on flux UDFs.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

c. Specify the **Unsteady Function** to be **none**, **default**, or a user-defined function (UDF). Select **none** for a steady state solution and **default** if you want the transient term in Equation 1.8 in the Theory Guide). See the separate Fluent Customization Manual for details on unsteady UDFs.

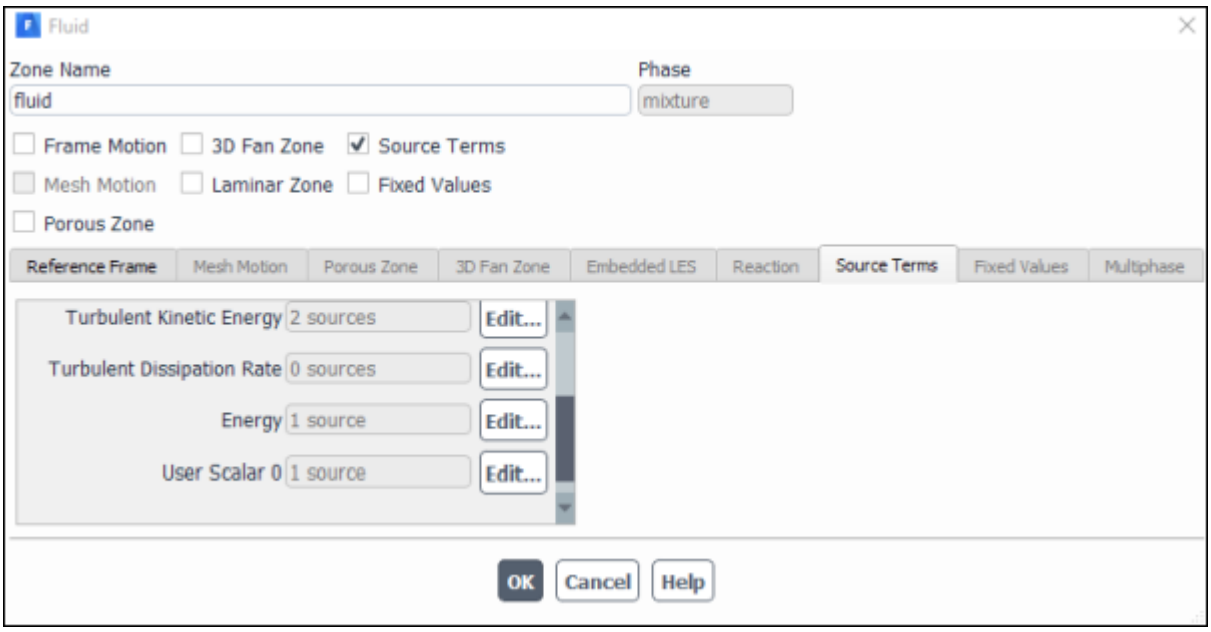
d. Repeat this process for each scalar equation by incrementing the **UDS Index**.

e. Click **OK** when all user scalar equations have been defined.

4. To specify source term(s) for each of the N UDS equations, enable the **Source Terms** option in the **Fluid** or **Solid** dialog box (Figure 9.2: The Fluid Dialog Box with Inputs for Source Terms for a User-Defined Scalar (p. 1714)) and click the **Source Terms** tab. The source parameters will be displayed.

Setup → Cell Zone Conditions

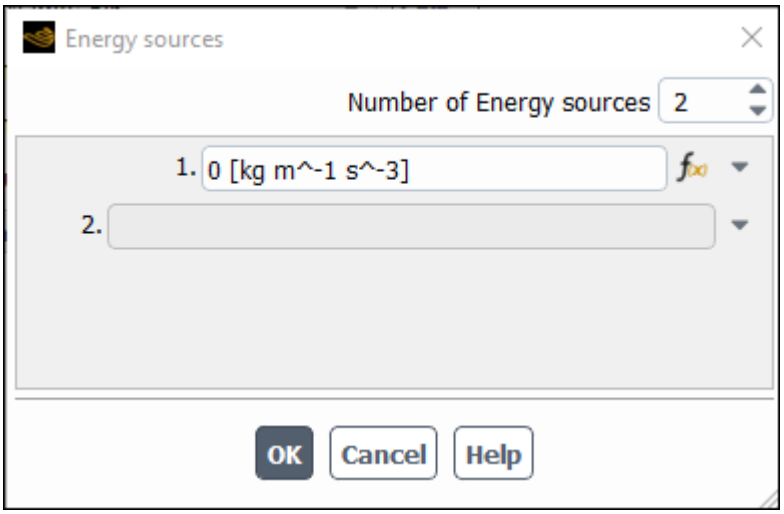
Figure 9.2: The Fluid Dialog Box with Inputs for Source Terms for a User-Defined Scalar



a. Specify the number of sources you require for each scalar equation by clicking on the **Edit...** button next to the scalar name (for example, **User Scalar 0**). This will open the **User Scalar 0 sources** dialog box (Figure 9.3: The User Scalar Sources Dialog Box (p. 1715)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 9.3: The User Scalar Sources Dialog Box



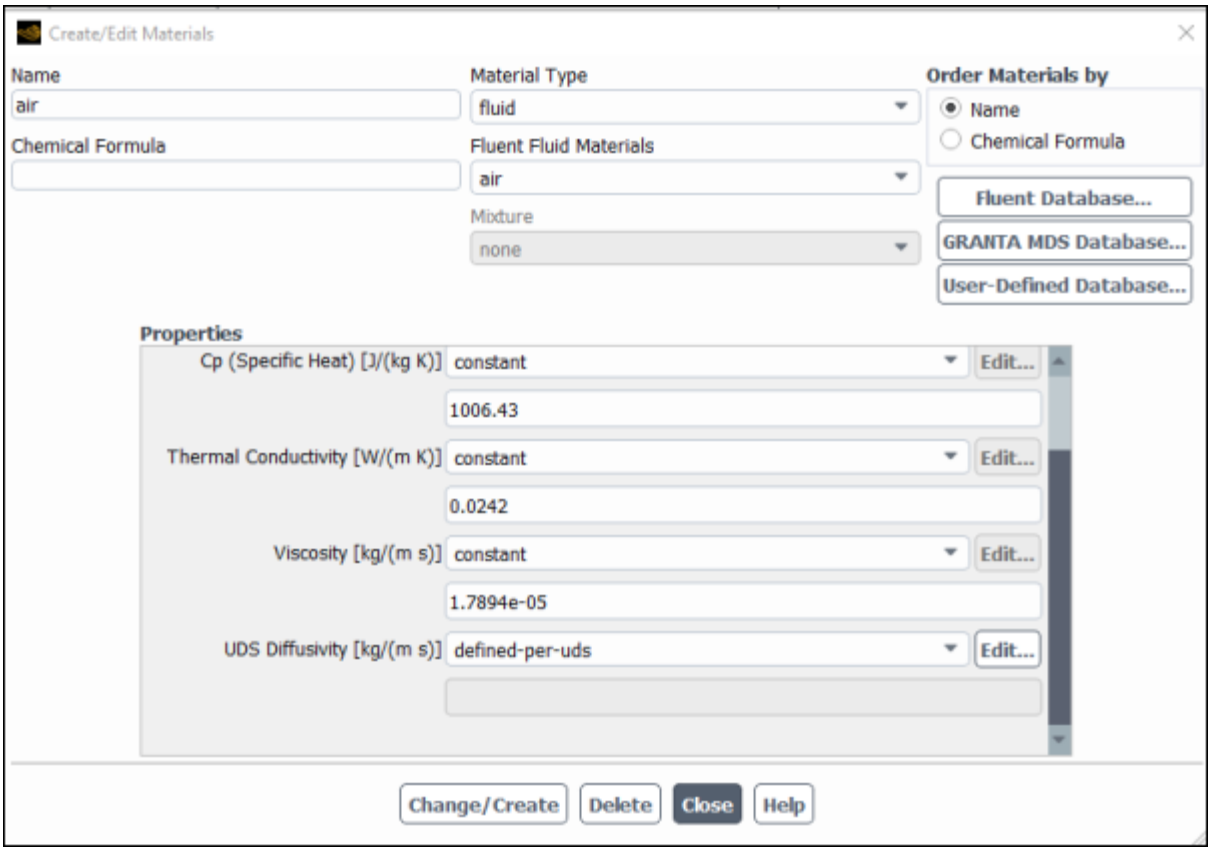
b. Specify the **Number of User Scalar Sources** for the scalar equation by incrementing the counter. Based on the value you have chosen, the sources will be added to the list in the dialog box. Specify each source to be **none**, **constant**, or a user-defined function (UDF). For details on defining a UDF scalar source, see the Fluent Customization Manual. Click **OK** when you have specified all scalar sources.

5. To specify diffusivity for each of the N UDS equations, display the Materials Task Page (p. 4831) (Figure 9.4: The Materials Dialog Box with Input for Diffusivity for UDS Equations (p. 1716)) and select either **defined-per-uds** (the default) or **user-defined** in the drop-down list for **UDS Diffusivity**.

Setup → **Materials** → **Create/Edit**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 9.4: The Materials Dialog Box with Input for Diffusivity for UDS Equations



See User-Defined Scalar (UDS) Diffusivity (p. 1630) for details on the different options available to you for defining diffusion coefficients.

6. To specify boundary conditions for the user-defined scalars on wall, inflow, and outflow boundaries, you can define a specific value or a specific flux for each scalar. A coupled boundary condition can be specified on two-sided walls for scalars that are to be solved in regions on both sides of the wall (that is, scalars solved in both **fluid and solid** zones).

   Setup → **Boundary Conditions**

   a. In the **UDS** tab under **User Defined Scalar Boundary Condition**, select either **Specified Flux** or **Specified Value** in the drop-down list next to each scalar (for example, **User Scalar 0**) for a boundary wall. For interior walls, select **Coupled Boundary** if the scalars are to be solved on both sides of a two-sided wall. Note that the **Coupled Boundary** option will only show up in the drop-down list if the scalar is defined in the **fluid and solid** zones in the User-Defined Scalars Dialog Box (p. 5596).

   b. Under **User Defined Scalar Boundary Value**, enter a constant value or select a user-defined function from the drop-down list for each scalar. If you select **Specified Flux**, your input will be the value of the flux at the boundary (that is, the negative of the term in parenthesis on the left-hand side of in the Theory Guide) dot [as in the dot product of] n [as in the vector, n], where n is the normal into the domain). If you select **Specified Value**, your input will be the value of the scalar itself at the boundary. See the Fluent Customization Manual for information on using UDFs for UDS boundary conditions.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7. Set the solution parameters in the **Solution Controls** task page, specify an initial value for each UDS (as you do for all other scalar transport equations), and calculate a solution.

8. Examine the results using the usual postprocessing tools. In each postprocessing dialog box, the list of field variables will include the **User Defined Scalars...** category, which contains the value of each UDS and its diffusion coefficient (Γ_k in Equation 1.8, Equation 1.9, Equation 1.10, or Equation 1.11 (in the Theory Guide):

   - **User Scalar-n**
   - **Diffusion Coef. of Scalar-n**

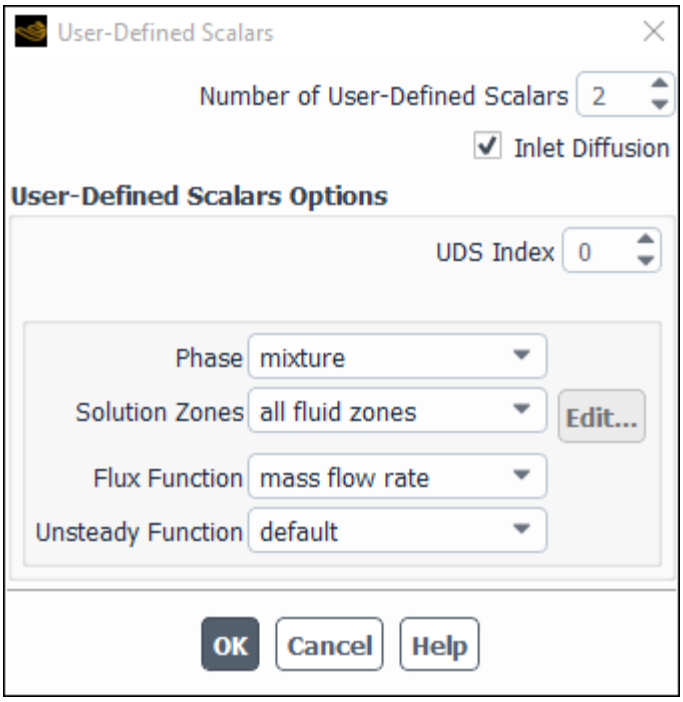
9.1.3.2. Multiphase Flow

1. Specify the number of scalars in the User-Defined Scalars Dialog Box (p. 5596) (Figure 9.5: The User-Defined Scalars Dialog Box for a Multiphase Flow (p. 1718)).

   Parameters & Customization → **User Defined Scalars** **New...**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 9.5: The User-Defined Scalars Dialog Box for a Multiphase Flow



Important:

The maximum number of user-defined scalar transport equations you can define is 50. Ansys Fluent assigns numbers to the equations starting with 0. The default association type is set to `mixture` for all scalars.

Important:

Note that Ansys Fluent assigns a default name for each scalar equation (`User Scalar 0`, `User Scalar 1`, and so on). These labels will appear in graphics dialog boxes in Ansys Fluent. You can change them by means of a UDF. See the Fluent Customization Manual for details.

2. Keep the default **Inlet Diffusion** enabled if you want to include the diffusion term in the UDS transport equation for all inflow and outflow boundaries.

3. Set the first user-defined scalar equation parameters by making sure that the **UDS Index** is set to 0.

   a. Select the **Phase** you want the scalar equation solved in as a primary phase, secondary phase, or the mixture.

   b. Specify the **Solution Zones** you want the scalar equation to be solved in as **all fluid zones**, **all solid zones**, **all zones** (fluid and solid) or **selected zones**. If you choose **selected zones**, click the **Edit** button to view the list of zones you can select.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

c. Specify the **Flux Function** to **Unsteady Function** the same way as you would for a single phase flow (see above).

d. Repeat this process for each scalar equation by incrementing the **UDS Index**.

e. Click **OK** when all user scalar equations have been defined.

4. Specify source term(s) for each of the N UDS equations in the **Fluid** or **Solid** dialog box as described for a single phase flow (see above).

5. Specify boundary conditions for the user-defined scalars in the mixture on all wall, inflow, and outflow boundary as described for a single phase flow (see above).

6. Set the solution parameters, specify an initial value for each UDS (as you do for all other scalar transport equations), and calculate a solution.

9.2. Periodic Flows

Periodic flow occurs when the physical geometry of interest and the expected pattern of the flow/thermal solution have a periodically repeating nature. Two types of periodic flow can be modeled in Ansys Fluent. In the first type, no pressure drop occurs across the periodic planes. In the second type, a pressure drop occurs across translationally periodic boundaries, resulting in "fully-developed" or "streamwise-periodic" flow.

This section discusses streamwise-periodic flow. A description of no-pressure-drop periodic flow is provided in Periodic Boundary Conditions (p. 1477), and a description of streamwise-periodic heat transfer is provided in Modeling Periodic Heat Transfer (p. 2238).

Information about streamwise-periodic flow is presented in the following sections:

9.2.1. Overview and Limitations

9.2.2. User Inputs for the Pressure-Based Solver

9.2.3. User Inputs for the Density-Based Solvers

9.2.4. Monitoring the Value of the Pressure Gradient

9.2.5. Postprocessing for Streamwise-Periodic Flows

For more information about the theoretical background of periodic flows, see Periodic Flows in the Theory Guide.

9.2.1. Overview and Limitations

More information about periodic flows is presented in the following sections:

9.2.1.1. Overview

9.2.1.2. Limitations for Modeling Streamwise-Periodic Flow

9.2.1.1. Overview

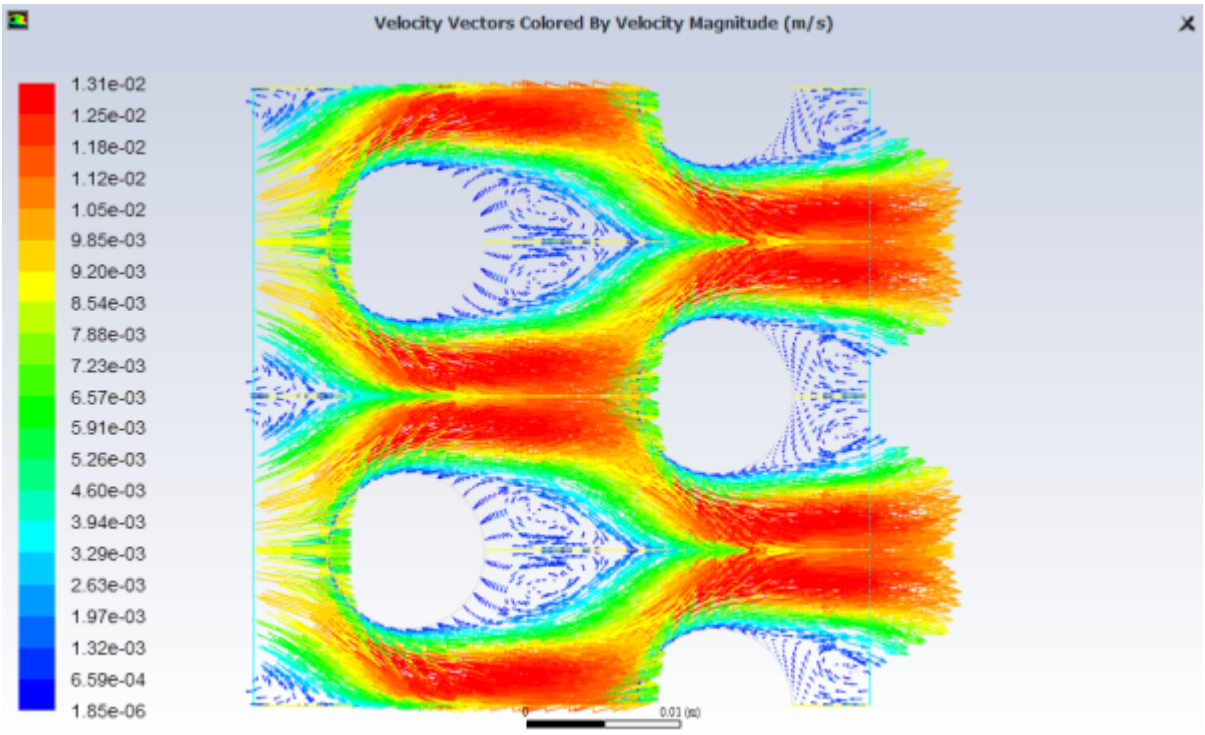
Ansys Fluent provides the ability to calculate streamwise-periodic—or "fully-developed"—fluid flow. These flows are encountered in a variety of applications, including flows in compact heat exchanger channels and flows across tube banks. In such flow configurations, the geometry varies in a repeating

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

manner along the direction of the flow, leading to a periodic fully-developed flow regime in which the flow pattern repeats in successive cycles. Other examples of streamwise-periodic flows include fully-developed flow in pipes and ducts. These periodic conditions are achieved after a sufficient entrance length, which depends on the flow Reynolds number and geometric configuration.

Streamwise-periodic flow conditions exist when the flow pattern repeats over some length L, with a constant pressure drop across each repeating module along the streamwise direction. Figure 9.6: Example of Periodic Flow in a 2D Heat Exchanger Geometry (p. 1720) depicts one example of a periodically repeating flow of this type that has been modeled by including a single representative module. Note that the figure shows the results plotted for the one periodic pair and two symmetries.

Figure 9.6: Example of Periodic Flow in a 2D Heat Exchanger Geometry



9.2.1.2. Limitations for Modeling Streamwise-Periodic Flow

The following limitations apply to modeling streamwise-periodic flow:

- The flow must be incompressible.
- When performing unsteady-state simulations with translational periodic boundary conditions, the specified pressure gradient is recommended.
- If one of the density-based solvers is used, you can specify only the pressure jump; for the pressure-based solver, you can specify either the pressure jump or the mass flow rate.
- No net mass addition through inlets/exits or extra source terms is allowed.
- Species can be modeled only if inlets/exits (without net mass addition) are included in the problem. Reacting flows are not permitted.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- When you specify a periodic mass-flow rate, Fluent will assume that the entire flow rate passes through one periodic continuous face zone only. It is not supported to define a mass-flow periodic condition for more than 1 periodic boundary condition (that is, it does not work for 2 periodic pairs).
- Steady particle tracks can be modeled only if the particles have a possibility to leave the domain without generating incomplete trajectories.
- While multiphase flow can be modeled with translational periodic boundary conditions, you cannot use the mass flow rate specification method. However, you can specify a constant pressure gradient.
- For the pressure-based solver, the periodic boundary condition with specified non-zero mass flow rate and/or pressure gradient cannot be used for variable density flows.
- For the density-based solver, the periodic pressure jump cannot be used when density is a function of pressure.
- When displaying contours of solution variables related to temperature and pressure (such as static temperature, enthalpy, and so on), each nodal value on the periodic boundary is calculated as the weighted average of the values in the cells contacting that node. Since no cells adjacent to the periodic shadow zone contribute to the average, contour values might differ between corresponding places on periodic zones and periodic shadow zones.

For periodic simulations that include heat transfer, see also the limitations described in Constraints for Periodic Heat Transfer Predictions (p. 2238).

9.2.2. User Inputs for the Pressure-Based Solver

Note:

The **Pressure Gradient** refers to the linear component of the calculated pressure gradient.

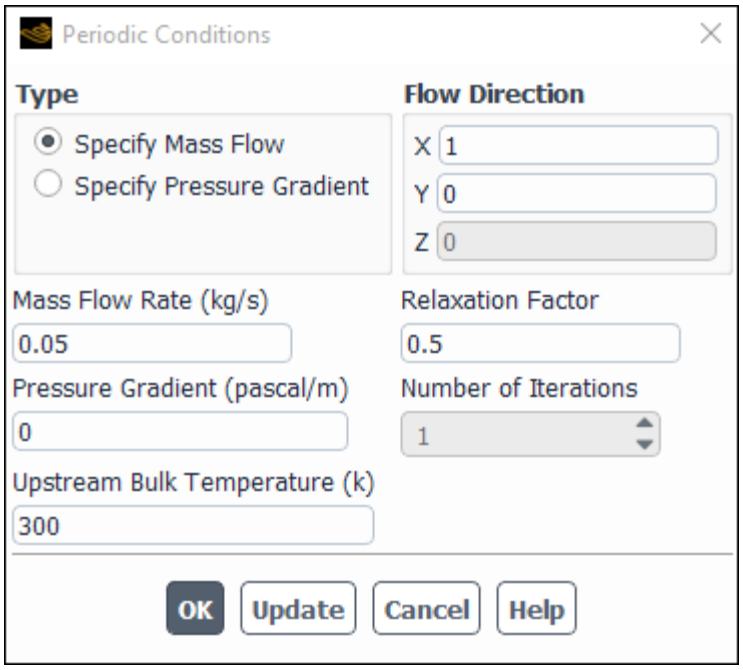
If you are using the pressure-based solver, in order to calculate a spatially periodic flow field with a specified mass flow rate or pressure derivative, you must first create a mesh with translationally periodic boundaries that are parallel to each other and equal in size. You can specify translational periodicity in the Periodic Conditions Dialog Box (p. 5050), as described in Periodic Boundary Conditions (p. 1477). (If you need to create periodic boundaries, see Creating Periodic Zones and Interfaces (p. 1246)).

In the Periodic Conditions Dialog Box (p. 5050) that is opened from the Boundary Conditions Task Page (p. 4937), you will complete the following inputs after the mesh has been read into Ansys Fluent (Figure 9.7: The Periodic Conditions Dialog Box (p. 1722)):

Setup → **Boundary Conditions** → **Periodic Conditions...**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 9.7: The Periodic Conditions Dialog Box



1. Select either the specified mass flow rate (**Specify Mass Flow**) option or the specified pressure gradient (**Specify Pressure Gradient**) option. For most problems, the mass flow rate across the periodic boundary will be a known quantity; for others, the mass flow rate will be unknown, but the pressure gradient (β in Equation 1.22, in the Theory Guide) will be a known quantity.

2. Specify the mass flow rate and/or the pressure gradient (β in Equation 1.22, in the Theory Guide):

   - If you selected the **Specify Mass Flow** option, enter the desired value for the **Mass Flow Rate**. You can also specify an initial guess for the **Pressure Gradient**, but this is not required.

     Important:

     For axisymmetric problems, the mass flow rate is per 2π radians.

   - If you selected the **Specify Pressure Gradient** option, enter the desired value for **Pressure Gradient**.

3. Define the flow direction by setting the **X,Y,Z** (or **X,Y** in 2D) point under **Flow Direction**. The flow will move in the direction of the vector pointing from the origin to the specified point. The direction vector must be parallel to the periodic translation direction or its opposite.

4. If you chose in step 1 to specify the mass flow rate, set the parameters used for the calculation of β. These parameters are described in detail below.

After completing these inputs, you can solve the periodic velocity field to convergence.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

9.2.2.1. Setting Parameters for the Calculation of β

If you choose to specify the mass flow rate, Ansys Fluent must calculate the appropriate value of the pressure gradient β. You can control this calculation by specifying the **Relaxation Factor** and the **Number of Iterations**, and by supplying an initial guess for β. All of these inputs are entered in the Periodic Conditions Dialog Box (p. 5050).

The **Number of Iterations** sets the number of sub-iterations performed on the correction of β in the pressure correction equation. Because the value of β is not known a priori, it must be iterated on until the **Mass Flow Rate** that you have defined is achieved in the computational model. This correction of β occurs in the pressure correction step of the SIMPLE, SIMPLEC, or PISO algorithm. A correction to the current value of β is calculated based on the difference between the desired mass flow rate and the actual one. The sub-iterations referred to here are performed within the pressure correction step to improve the correction for β before the pressure correction equation is solved for the resulting pressure (and velocity) correction values. The default value of 2 sub-iterations should suffice in most problems, but can be increased to help speed convergence. The **Relaxation Factor** is an under-relaxation factor that controls convergence of this iteration process.

You can also speed up convergence of the periodic calculation by supplying an initial guess for β in the **Pressure Gradient** field. Note that the current value of β will be displayed in this field if you have performed any calculations. To update the **Pressure Gradient** field with the current value at any time, click the **Update** button.

9.2.3. User Inputs for the Density-Based Solvers

If you are using one of the density-based solvers, in order to calculate a spatially periodic flow field with a specified pressure jump, you must first create a mesh with translationally periodic boundaries that are parallel to each other and equal in size. (If you need to create periodic boundaries, see Creating Periodic Zones and Interfaces (p. 1246).)

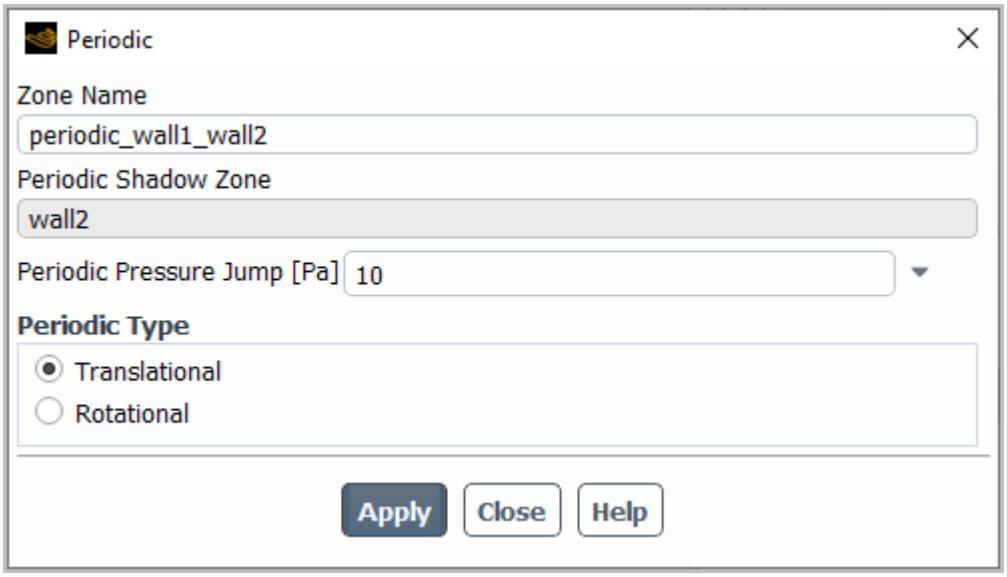
Then, follow the steps below:

1. In the Periodic Dialog Box (p. 4987) (Figure 9.8: The Periodic Dialog Box (p. 1724)), which is opened from the **Boundary Conditions** task page, indicate that the periodicity is **Translational** (the default).

   Setup → **Boundary Conditions** → **Periodic** → **Edit...**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 9.8: The Periodic Dialog Box



2. Also in the Periodic Dialog Box (p. 4987), set the **Periodic Pressure Jump** (Δp in Equation 1.21 in the Theory Guide).

After completing these inputs, you can solve the periodic velocity field to convergence.

9.2.4. Monitoring the Value of the Pressure Gradient

If you have specified the mass flow rate, you can monitor the value of the pressure gradient β during the calculation by creating a report plot that includes periodic pressure gradient, to ensure that you reach a converged solution. See Monitoring Statistics (p. 3681) for additional information.

9.2.5. Postprocessing for Streamwise-Periodic Flows

Note:

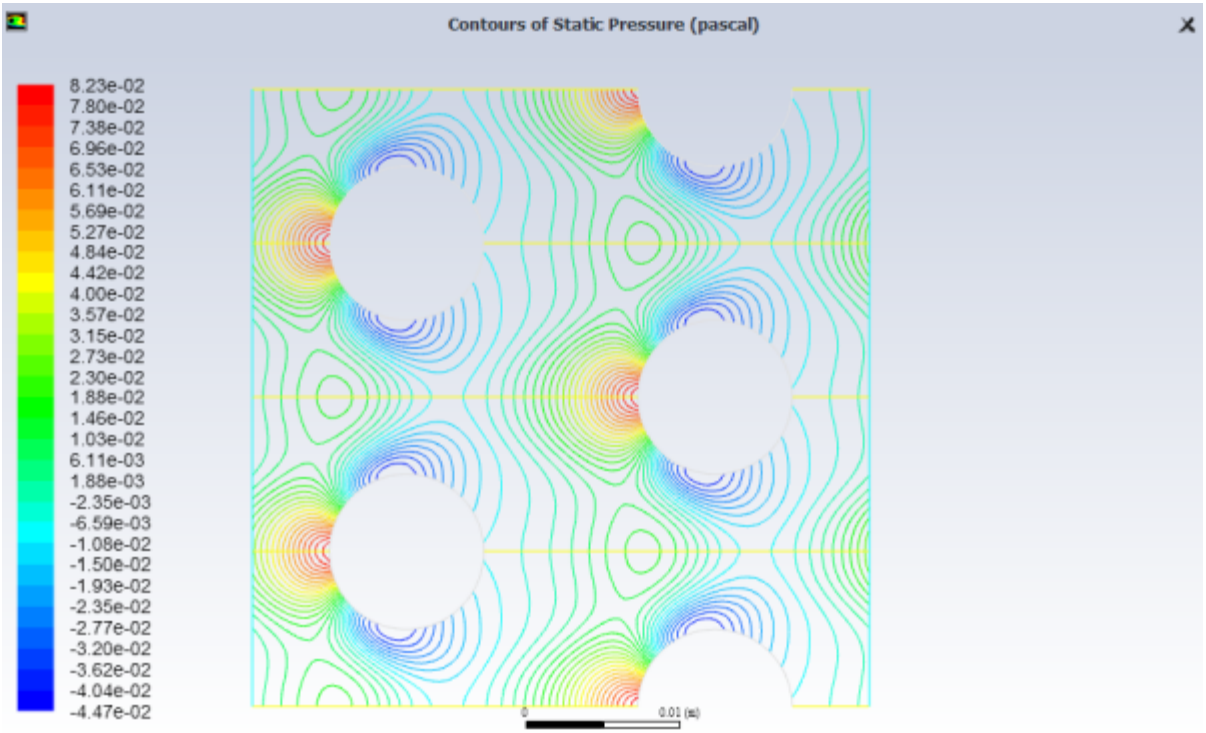
Contours of **Pressure Gradient** are represented by an auxiliary pressure field used by the solver and does not represent a real value.

For streamwise-periodic flows, the velocity field should be completely periodic. If a density-based solver is used to compute the periodic flow, only the linear component of the pressure field will be reported (which is not periodic). If the pressure-based solver is used, the pressure field reported will be the periodic pressure field $\tilde{p}(\vec{r})$ of Equation 1.22, in the Theory Guide. Figure 9.9: Periodic Pressure Field Predicted for Flow in a 2D Heat Exchanger Geometry (p. 1725) displays the periodic pressure field in the geometry of Figure 9.6: Example of Periodic Flow in a 2D Heat Exchanger Geometry (p. 1720).

If you specified a mass flow rate and had Ansys Fluent calculate the pressure gradient, you can check the pressure gradient in the streamwise direction (β) by looking at the current value for **Pressure Gradient** in the Periodic Conditions Dialog Box (p. 5050).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 9.9: Periodic Pressure Field Predicted for Flow in a 2D Heat Exchanger Geometry



9.3. Swirling and Rotating Flows

Many important engineering flows involve swirl or rotation and Ansys Fluent is well-equipped to model such flows. Swirling flows are common in combustion, with swirl introduced in burners and combustors in order to increase residence time and stabilize the flow pattern. Rotating flows are also encountered in turbomachinery, mixing tanks, and a variety of other applications.

Information about rotating and swirling flows is provided in the following subsections:

9.3.1. Overview of Swirling and Rotating Flows
9.3.2. Turbulence Modeling in Swirling Flows
9.3.3. Mesh Setup for Swirling and Rotating Flows
9.3.4. Modeling Axisymmetric Flows with Swirl or Rotation

For more information about the theoretical background of swirling and rotating flows, see Swirling and Rotating Flows in the Theory Guide.

When you begin the analysis of a rotating or swirling flow, it is essential that you classify your problem into one of the following five categories of flow:

- axisymmetric flows with swirl or rotation
- fully three-dimensional swirling or rotating flows
- flows requiring a moving reference frame
- flows requiring multiple moving reference frames or mixing planes

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- flows requiring sliding meshes

Modeling and solution procedures for the first two categories are presented in this section. The remaining three, which all involve "moving zones", are discussed in Modeling Flows with Moving Reference Frames (p. 1741).

9.3.1. Overview of Swirling and Rotating Flows

An overview of swirling and rotating flows is presented in the following sections:

9.3.1.1. Axisymmetric Flows with Swirl or Rotation

9.3.1.2. Three-Dimensional Swirling Flows

9.3.1.3. Flows Requiring a Moving Reference Frame

9.3.1.1. Axisymmetric Flows with Swirl or Rotation

Your problem may be axisymmetric with respect to geometry and flow conditions but still include swirl or rotation. In this case, you can model the flow in 2D (that is, solve the axisymmetric problem) and include the prediction of the circumferential (or swirl) velocity. It is important to note that while the assumption of axisymmetry implies that there are no circumferential gradients in the flow, there may still be nonzero swirl velocities.

9.3.1.1.1. Momentum Conservation Equation for Swirl Velocity

The tangential momentum equation for 2D swirling flows may be written as

$$\frac{\partial}{\partial t}\left(\rho w\right)+\frac{1}{r}\frac{\partial}{\partial x}\left(r\rho uw\right)+\frac{1}{r}\frac{\partial}{\partial r}\left(r\rho vw\right) = \frac{1}{r}\frac{\partial}{\partial x}\left[r\mu\frac{\partial w}{\partial x}\right] + \frac{1}{r^2}\frac{\partial}{\partial r}\left[r^3\mu\frac{\partial}{\partial r}\left(\frac{w}{r}\right)\right] - \rho\frac{vw}{r} \tag{9.14}$$

where x is the axial coordinate, r is the radial coordinate, u is the axial velocity, v is the radial velocity, and w is the swirl velocity.

9.3.1.2. Three-Dimensional Swirling Flows

When there are geometric changes and/or flow gradients in the circumferential direction, your swirling flow prediction requires a three-dimensional model. If you are planning a 3D Ansys Fluent model that includes swirl or rotation, you should be aware of the setup constraints listed in Coordinate System Restrictions (p. 1728). In addition, you might consider simplifications to the problem that might reduce it to an equivalent axisymmetric problem, especially for your initial modeling effort. Because of the complexity of swirling flows, an initial 2D study, in which you can quickly determine the effects of various modeling and design choices, can be very beneficial.

Important:

For 3D problems involving swirl or rotation, there are no special inputs required during the problem setup and no special solution procedures. Note, however, that you may want to use the cylindrical coordinate system for defining velocity-inlet boundary condition inputs, as described in Defining the Velocity (p. 1391). Also, you may find the gradual increase of the rotational speed (set as a wall or inlet boundary condition) helpful during

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the solution process. This is described for axisymmetric swirling flows in Improving Solution Stability by Gradually Increasing the Rotational or Swirl Speed (p. 1731).

9.3.1.3. Flows Requiring a Moving Reference Frame

If your flow involves a rotating boundary that moves through the fluid (for example, an impeller blade or a grooved or notched surface), you must use a moving reference frame to model the problem. Such applications are described in detail in Introduction (p. 1741). If you have more than one rotating boundary (for example, several impellers in a row), you can use multiple reference frames (described in The Multiple Reference Frame Model (p. 1751)) or mixing planes (described in Legacy Mixing Plane Model (p. 1934)).

9.3.2. Turbulence Modeling in Swirling Flows

If you are modeling turbulent flow with a significant amount of swirl (for example, cyclone flows, swirling jets), you should consider using one of Ansys Fluent's advanced turbulence models: the RNG k- ε model, realizable k- ε model, or Reynolds stress model. The appropriate choice depends on the strength of the swirl, which can be gauged by the swirl number. The swirl number is defined as the ratio of the axial flux of angular momentum to the axial flux of axial momentum:

$$S=\frac{\int rw\vec{v}\cdot d\vec{A}}{\overline{R}\int u\vec{v}\cdot d\vec{A}} \tag{9.15}$$

where $\overline{R}$ is the hydraulic radius.

For flows with weak to moderate swirl ($S<0.5$), both the RNG k- ε model and the realizable k- ε model yield appreciable improvements over the standard k- ε model. See RNG k-ε Model and Realizable k-ε Model Swirl Modification (p. 2100) for details about these models.

For highly swirling flows ($S>0.5$), the Reynolds stress model (RSM) is strongly recommended. The effects of strong turbulence anisotropy can be modeled rigorously only by the second-moment closure adopted in the RSM. See Reynolds Stress Model (RSM) Steps in Using a Turbulence Model (p. 2045) for details about this model.

For swirling flows encountered in devices such as cyclone separators and swirl combustors, near-wall turbulence modeling is quite often a secondary issue at most. The fidelity of the predictions in these cases is mainly determined by the accuracy of the turbulence model in the core region. However, in cases where walls actively participate in the generation of swirl (that is, where the secondary flows and vortical flows are generated by pressure gradients), non-equilibrium wall functions can often improve the predictions since they use a law of the wall for mean velocity sensitized to pressure gradients. See Near-Wall Treatments for Wall-Bounded Turbulent Flows in the Theory Guide for additional details about near-wall treatments for turbulence.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

9.3.3. Mesh Setup for Swirling and Rotating Flows

9.3.3.1. Coordinate System Restrictions

Recall that for an axisymmetric problem, the axis of rotation must be the x axis and the mesh must lie on or above the $y=0$ line.

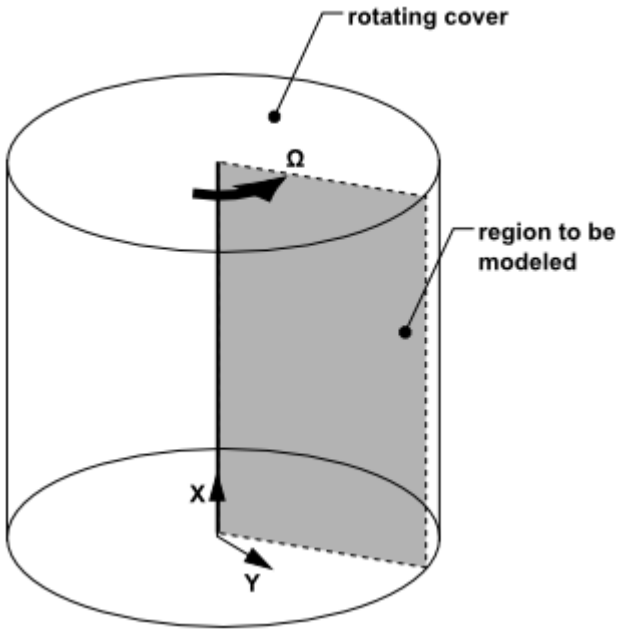
9.3.3.2. Mesh Sensitivity in Swirling and Rotating Flows

In addition to the setup constraint described above, you should be aware of the need for sufficient resolution in your mesh when solving flows that include swirl or rotation. Typically, rotating boundary layers may be very thin, and your Ansys Fluent model will require a very fine mesh near a rotating wall. In addition, swirling flows will often involve steep gradients in the circumferential velocity (for example, near the centerline of a free-vortex type flow), and therefore require a fine mesh for accurate resolution.

9.3.4. Modeling Axisymmetric Flows with Swirl or Rotation

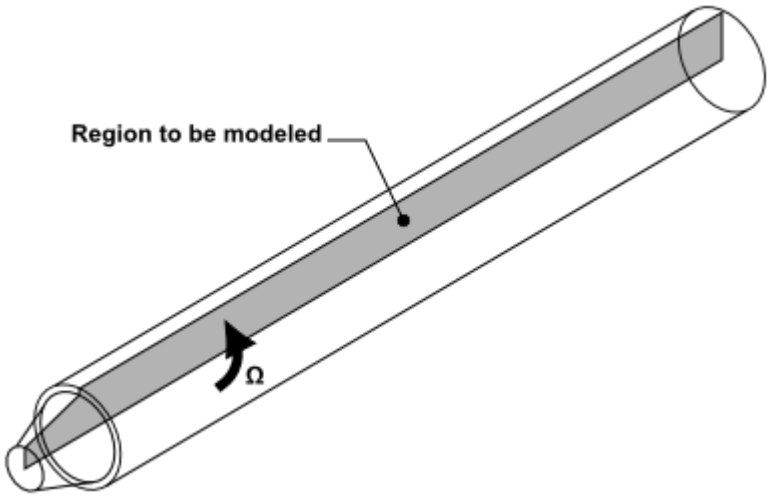
As discussed in Overview of Swirling and Rotating Flows (p. 1726), you can solve a 2D axisymmetric problem that includes the prediction of the circumferential or swirl velocity. The assumption of axisymmetry implies that there are no circumferential gradients in the flow, but that there may be nonzero circumferential velocities. Examples of axisymmetric flows involving swirl or rotation are depicted in Figure 9.10: Rotating Flow in a Cavity (p. 1728) and Figure 9.11: Swirling Flow in a Gas Burner (p. 1729).

Figure 9.10: Rotating Flow in a Cavity



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 9.11: Swirling Flow in a Gas Burner



9.3.4.1. Problem Setup for Axisymmetric Swirling Flows

For axisymmetric problems, you must perform the following steps during the problem setup procedure. (Only those steps relevant specifically to the setup of axisymmetric swirl/rotation are listed here. You must set up the rest of the problem as usual.)

1. Enable the solution of the momentum equation in the circumferential direction by turning on the **Axisymmetric Swirl** option for **Space** in the **General** task page.

   Setup → **General** → **Axisymmetric Swirl**

2. Define the rotational or swirling component of velocity, $r\Omega$, at inlets or walls.

   Setup → **Boundary Conditions**

   Important:

   Remember to use the axis boundary type for the axis of rotation.

The procedures for input of rotational velocities at inlets and at walls are described in detail in Defining the Velocity (p. 1391) and Velocity Conditions for Moving Walls (p. 1440).

9.3.4.2. Solution Strategies for Axisymmetric Swirling Flows

The difficulties associated with solving swirling and rotating flows are a result of the high degree of coupling between the momentum equations, which is introduced when the influence of the rotational terms is large. A high level of rotation introduces a large radial pressure gradient that drives the flow in the axial and radial directions. This, in turn, determines the distribution of the swirl or rotation in the field. This coupling may lead to instabilities in the solution process, and you may require special solution techniques in order to obtain a converged solution. Solution techniques that may be beneficial in swirling or rotating flow calculations include the following:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- (Pressure-based segregated solver only) Use the PRESTO! scheme (enabled in the **Pressure** list for **Spatial Discretization** in the Solution Methods Task Page (p. 5103)), which is well-suited for the steep pressure gradients involved in swirling flows.
- Ensure that the mesh is sufficiently refined to resolve large gradients in pressure and swirl velocity.
- (Pressure-based solver only) Change the under-relaxation parameters on the velocities, perhaps to 0.3–0.5 for the radial and axial velocities and 0.8–1.0 for swirl.
- (Pressure-based solver only) Use a sequential or step-by-step solution procedure, in which some equations are temporarily left inactive (see below).
- If necessary, start the calculations using a low rotational speed or inlet swirl velocity, increasing the rotation or swirl gradually in order to reach the final desired operating condition (see below).

See Using the Solver (p. 3557) for details on the procedures used to make these changes to the solution parameters. More details on the step-by-step procedure and on the gradual increase of the rotational speed are provided below.

9.3.4.2.1. Step-By-Step Solution Procedures for Axisymmetric Swirling Flows

Often, flows with a high degree of swirl or rotation will be easier to solve if you use the following step-by-step solution procedure, in which only selected equations are left active in each step. This approach allows you to establish the field of angular momentum, then leave it fixed while you update the velocity field, and then finally to couple the two fields by solving all equations simultaneously.

Important:

Since the density-based solvers solve all the flow equations simultaneously, the following procedure applies only to the pressure-based solver.

In this procedure, you will use the **Equations...** button in the Solution Controls Task Page (p. 5109) to turn individual transport equations on and off between calculations.

1. If your problem involves inflow/outflow, begin by solving the flow without rotation or swirl effects. That is, enable the **Axisymmetric** option instead of the **Axisymmetric Swirl** option in the General Task Page (p. 4632), and do not set any rotating boundary conditions. The resulting flow-field data can be used as a starting guess for the full problem.
2. Enable the **Axisymmetric Swirl** option and set all rotating/swirling boundary conditions.
3. Begin the prediction of the rotating/swirling flow by solving only the momentum equation describing the circumferential velocity. This is the **Swirl Velocity** listed in the **Equations** list in the Equations Dialog Box (p. 5112). Let the rotation "diffuse" throughout the flow field, based on your boundary condition inputs. In a turbulent flow simulation, you may also want to leave the turbulence equations active during this step. This step will establish the field of rotation throughout the domain.
4. Turn off the momentum equations describing the circumferential motion (**Swirl Velocity**). Leaving the velocity in the circumferential direction fixed, solve the momentum and continuity (pressure) equations (**Flow** in the **Equations** list in the Equations Dialog Box (p. 5112)) in the

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

other coordinate directions. This step will establish the axial and radial flows that are a result of the rotation in the field. Again, if your problem involves turbulent flow, you should leave the turbulence equations active during this calculation.

5. Turn on all of the equations simultaneously to obtain a fully coupled solution. Note the under-relaxation controls suggested above.

In addition to the steps above, you may want to simplify your calculation by solving isothermal flow before adding heat transfer or by solving laminar flow before adding a turbulence model. These two methods can be used for any of the solvers (that is, pressure-based or density-based).

9.3.4.2.2. Improving Solution Stability by Gradually Increasing the Rotational or Swirl Speed

Because the rotation or swirl defined by the boundary conditions can lead to large complex forces in the flow, your Ansys Fluent calculations will be less stable as the speed of rotation or degree of swirl increases. Hence, one of the most effective controls you can apply to the solution is to solve your rotating flow problem starting with a low rotational speed or swirl velocity and then slowly increase the magnitude up to the desired level. The procedure for accomplishing this is as follows:

1. Set up the problem using a low rotational speed or swirl velocity in your inputs for boundary conditions. The rotation or swirl in this first attempt might be selected as 10% of the actual operating conditions.

2. Solve the problem at these conditions, perhaps using the step-by-step solution strategy outlined above.

3. Save this initial solution data.

4. Modify your inputs (boundary conditions). Increase the speed of rotation, perhaps doubling it.

5. Restart the calculation using the solution data saved in step 3 as the initial solution for the new calculation. Save the new data.

6. Continue to increment the speed of rotation, following steps 4 and 5, until you reach the desired operating condition.

9.3.4.2.2.1. Postprocessing for Axisymmetric Swirling Flows

Reporting of results for axisymmetric swirling flows is the same as for other flows. The following additional variables are available for postprocessing when axisymmetric swirl is active:

- **Swirl Velocity** (in the **Velocity...** category)
- **Swirl-Wall Shear Stress** (in the **Wall Fluxes...** category)

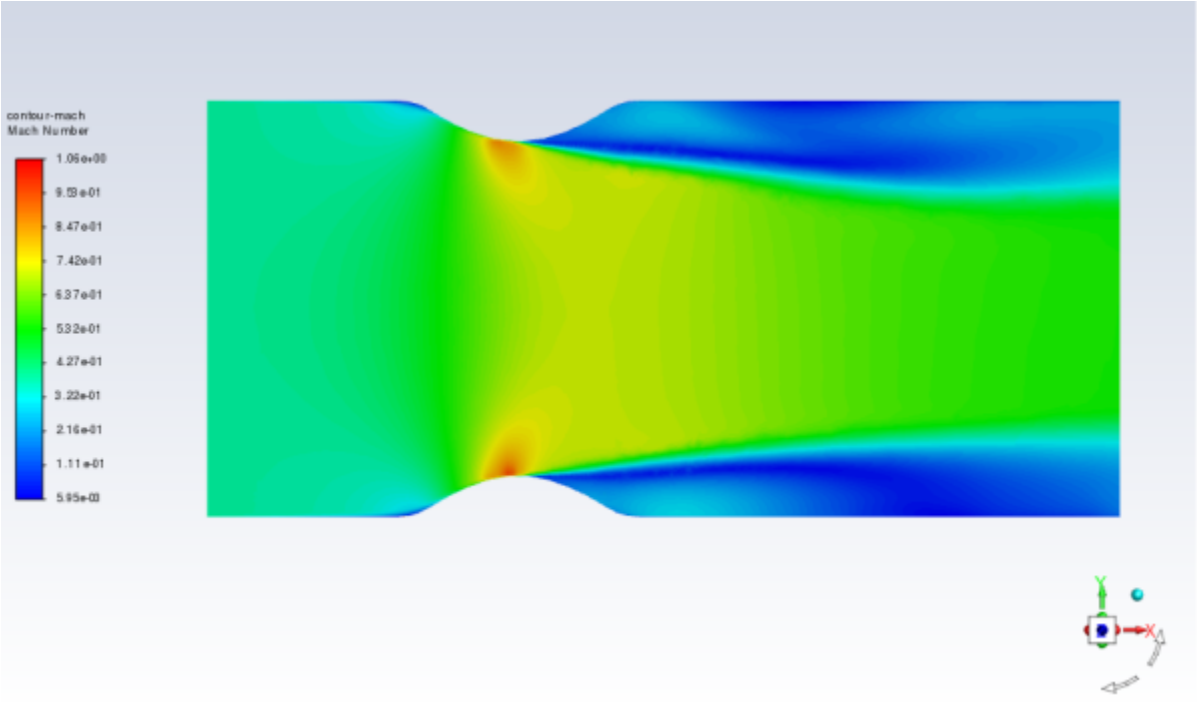
9.4. Compressible Flows

Compressibility effects are encountered in gas flows at high velocity and/or in which there are large pressure variations. When the flow velocity approaches or exceeds the speed of sound of the gas or

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

when the pressure change in the system ($\Delta p / p$) is large, the variation of the gas density with pressure has a significant impact on the flow velocity, pressure, and temperature. Compressible flows create a unique set of flow physics for which you must be aware of the special input requirements and solution techniques described in this section. Figure 9.12: Flow in a Converging-Diverging Nozzle (p. 1732) shows compressible flows computed using Ansys Fluent.

Figure 9.12: Flow in a Converging-Diverging Nozzle



Information about compressible flows is provided in the following subsections:

- 9.4.1. When to Use the Compressible Flow Model
- 9.4.2. Physics of Compressible Flows
- 9.4.3. Modeling Inputs for Compressible Flows
- 9.4.4. Floating Operating Pressure
- 9.4.5. Solution Strategies for Compressible Flows
- 9.4.6. Reporting of Results for Compressible Flows

For more information about the theoretical background of compressible flows, see Compressible Flows in the Theory Guide.

9.4.1. When to Use the Compressible Flow Model

Compressible flows can be characterized by the value of the Mach number:

$$M \equiv u / c \tag{9.16}$$

Here, c is the speed of sound in the gas:

$$c = \sqrt{\gamma R T} \tag{9.17}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

and γ is the ratio of specific heats $\left(c_p / c_v\right)$.

When the Mach number is less than 1.0, the flow is termed subsonic. At Mach numbers much less than 1.0 (M 0.1 or so), compressibility effects are negligible and the variation of the gas density with pressure can safely be ignored in your flow modeling. As the Mach number approaches 1.0 (which is referred to as the transonic flow regime), compressibility effects become important. When the Mach number exceeds 1.0, the flow is termed supersonic, and may contain shocks and expansion fans which can impact the flow pattern significantly. Ansys Fluent provides a wide range of compressible flow modeling capabilities for subsonic, transonic, and supersonic flows.

9.4.2. Physics of Compressible Flows

Compressible flows are typically characterized by the total pressure p_0 and total temperature T_0 of the flow. For an ideal gas, these quantities can be related to the static pressure and temperature by the following:

$$\frac{p_0}{p} = exp\left(\frac{\int_T^{T_0} \frac{C_p}{T} dT}{R}\right) \tag{9.18}$$

For constant C_p, Equation 9.18 (p. 1733) reduces to

$$\begin{aligned} \frac{p_0}{p} &= \left(1+\frac{\gamma-1}{2}M^2\right)^{\gamma/(\gamma-1)} \\ \frac{T_0}{T} &= 1+\frac{\gamma-1}{2}M^2 \end{aligned} \tag{9.19}$$

These relationships describe the variation of the static pressure and temperature in the flow as the velocity (Mach number) changes under isentropic conditions. For example, given a pressure ratio from inlet to exit (total to static), Equation 9.19 (p. 1733) can be used to estimate the exit Mach number that would exist in a one-dimensional isentropic flow. For air, Equation 9.19 (p. 1733) p / p_0, of 0.5283. This choked flow condition will be established at the point of minimum flow area (for example, in the throat of a nozzle). In the subsequent area expansion the flow may either accelerate to a supersonic flow in which the pressure will continue to drop, or return to subsonic flow conditions, decelerating with a pressure rise. If a supersonic flow is exposed to an imposed pressure increase, a shock will occur, with a sudden pressure rise and deceleration accomplished across the shock.

9.4.2.1. Basic Equations for Compressible Flows

Compressible flows are described by the standard continuity and momentum equations solved by Ansys Fluent, and you do not need to enable any special physical models (other than the compressible treatment of density as detailed below). The energy equation solved by Ansys Fluent correctly incorporates the coupling between the flow velocity and the static temperature, and should be activated whenever you are solving a compressible flow. In addition, if you are using the pressure-based solver, you should enable the viscous dissipation terms in Equation 5.1 in the Theory Guide, which become important in high-Mach-number flows.

9.4.2.2. The Compressible Form of the Gas Law

For compressible flows, the ideal gas law is written in the following form:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\rho = \frac{p_{op} + p}{\frac{R}{M_w} T} \tag{9.20}$$

where p_{op} is the operating pressure defined in the Operating Conditions Dialog Box (p. 4926), p is the local static pressure relative to the operating pressure, R is the universal gas constant, and M_w is the molecular weight. The temperature, T, will be computed from the energy equation.

Some compressible flow problems involve fluids that do not behave as ideal gases. For example, flow under very high-pressure conditions cannot typically be modeled accurately using the ideal-gas assumption. Therefore, the real gas model described in Real Gas Models (p. 1655) should be used instead.

9.4.3. Modeling Inputs for Compressible Flows

To set up a compressible flow in Ansys Fluent, you must follow the steps listed below. (Only those steps relevant specifically to the setup of compressible flows are listed here. You must set up the rest of the problem as usual.)

1. Set the **Operating Pressure** in the Operating Conditions Dialog Box (p. 4926).

   Setup → **Boundary Conditions** → **Operating Conditions...**

   (You can think of p_{op} as the absolute static pressure at a point in the flow where you will define the gauge pressure p to be zero. See Operating Pressure (p. 1651) for guidelines on setting the operating pressure. For time-dependent compressible flows, you may want to specify a floating operating pressure instead of a constant operating pressure. See Floating Operating Pressure (p. 1735) for details.)

2. Enable the solution of the energy equation.

   Setup → **Models** → **Energy** **On**

3. (Pressure-based solver only) If you are modeling turbulent flow, enable the optional viscous dissipation terms in the energy equation by turning on **Viscous Heating** in the Viscous Model Dialog Box (p. 4663). Note that these terms can be important in high-speed flows.

   Setup → **Models** → **Viscous** → **Edit...**

   This step is not necessary if you are using one of the density-based solvers, because the density-based solvers always include the viscous dissipation terms in the energy equation.

4. Set the following items in the Create/Edit Materials Dialog Box (p. 4833):

   Setup → **Materials** → **Create/Edit...**

   a. Select **ideal-gas** in the drop-down list next to **Density**.

   b. Define all relevant properties (specific heat, molecular weight, thermal conductivity, and so on).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Set cell zone conditions and boundary conditions (using the Boundary Conditions Task Page (p. 4937) and Cell Zone Conditions Task Page (p. 4906)), being sure to choose a well-posed cell zone or boundary condition combination that is appropriate for the flow regime. See below for details. Recall that all inputs for pressure (either total pressure or static pressure) must be relative to the operating pressure, and the temperature inputs at inlets should be total (stagnation) temperatures, *not* static temperatures.

   Setup → Cell Zone Conditions

   Setup → Boundary Conditions

These inputs should ensure a well-posed compressible flow problem. You will also want to consider special solution parameter settings, as noted in Solution Strategies for Compressible Flows (p. 1737), before beginning the flow calculation.

9.4.3.1. Boundary Conditions for Compressible Flows

Well-posed inlet and exit boundary conditions for compressible flow are listed below:

- For flow inlets:
  - Pressure inlet: Inlet total temperature and total pressure and, for supersonic inlets, static pressure
  - Mass-flow inlet: Inlet mass flow and total temperature
- For flow exits:
  - Pressure outlet: Exit static pressure (ignored if flow is supersonic at the exit. All the information travels downstream in a supersonic region, hence the pressure at the outlet can be computed by directly extrapolating from the adjacent cell center [61] (p. 5658). Therefore, it is not meaningful to use the exit static pressure prescribed in the boundary conditions task page, and the exit static pressure is ignored).
  - Mass-flow outlet: Outlet mass flow

It is important to note that your boundary condition inputs for pressure (either total pressure or static pressure) must be in terms of gauge pressure — that is, pressure relative to the operating pressure defined in the Operating Conditions Dialog Box (p. 4926), as described above.

All temperature inputs at inlets should be total (stagnation) temperatures, *not* static temperatures.

9.4.4. Floating Operating Pressure

Ansys Fluent provides a "floating operating pressure" option to handle time-dependent compressible flows with a gradual increase in the absolute pressure in the domain. This option is desirable for slow subsonic flows with static pressure build-up, since it efficiently accounts for the slow changing of absolute pressure without using acoustic waves as the transport mechanism for the pressure build-up.

Examples of typical applications include the following:

- combustion or heating of a gas in a closed domain

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- pumping of a gas into a closed domain

9.4.4.1. Limitations

The floating operating pressure option should *not* be used for transonic or incompressible flows. In addition, it cannot be used if your model includes any pressure inlet, pressure outlet, exhaust fan, inlet vent, intake fan, outlet vent, or pressure far field boundaries.

9.4.4.2. Theory

The floating operating pressure option allows Ansys Fluent to calculate the pressure rise (or drop) from the integral mass balance, separately from the solution of the pressure correction equation. When this option is activated, the absolute pressure at each iteration can be expressed as

$$p_{abs} = p_{op,float} + p \tag{9.21}$$

where p is the pressure relative to the reference location, which in this case is in the cell with the minimum pressure value. Therefore the reference location itself is floating.

$p_{op,float}$ is referred to as the floating operating pressure, and is defined as

$$p_{op,float} = p^0_{op} + \Delta p_{op} \tag{9.22}$$

where p^0_{op} is the initial operating pressure and Δp_{op} is the pressure rise.

Including the pressure rise Δp_{op} in the floating operating pressure $p_{op,float}$, rather than in the pressure p, helps to prevent roundoff error. If the pressure rise were included in p, the calculation of the pressure gradient for the momentum equation would give an inexact balance due to precision limits for 32-bit real numbers.

9.4.4.3. Enabling Floating Operating Pressure

When time dependence is active, you can turn on the **Floating Operating Pressure** option in the Operating Conditions Dialog Box (p. 4926).

Setup → **Boundary Conditions** → **Operating Conditions...**

(Note that the inputs for **Reference Pressure Location** will disappear when you enable **Floating Operating Pressure**, since these inputs are no longer relevant.)

Important:

The floating operating pressure option should *not* be used for transonic flows or for incompressible flows. It is meaningful only for slow subsonic flows of ideal or real gases, when the characteristic time scale is much larger than the sonic time scale.

9.4.4.4. Setting the Initial Value for the Floating Operating Pressure

When the floating operating pressure option is enabled, you must specify a value for the **Initial Operating Pressure** in the Solution Initialization Task Page (p. 5125).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Solution → **Initialization**

This initial value is stored in the case file with all your other initial values.

9.4.4.5. Storage and Reporting of the Floating Operating Pressure

The current value of the floating operating pressure is stored in the data file. If you visit the Operating Conditions Dialog Box (p. 4926) after a number of time steps have been performed, the current value of the **Operating Pressure** will be displayed.

Note that the floating operating pressure will automatically be reset to the initial operating pressure if you reset the data (that is, start over at the first iteration of the first time step).

9.4.4.6. Monitoring Absolute Pressure

You can monitor the absolute pressure during the calculation using the Surface Report Definition Dialog Box (p. 5568). You can also generate graphical plots or alphanumeric reports of absolute pressure when your solution is complete. The **Absolute Pressure** variable is contained in the **Pressure...** category of the variable selection drop-down list that appears in postprocessing dialog boxes. See Field Function Definitions (p. 4133) for its definition.

9.4.5. Solution Strategies for Compressible Flows

The difficulties associated with solving compressible flows are a result of the high degree of coupling between the flow velocity, density, pressure, and energy. This coupling may lead to instabilities in the solution process and, therefore, may require special solution techniques in order to obtain a converged solution. In addition, the presence of shocks (discontinuities) in the flow introduces an additional stability problem during the calculation. Solution techniques that may be beneficial in compressible flow calculations include the following:

- (Pressure-based solver only) Initialize the flow to be near stagnation (that is velocity small but not zero, pressure to inlet total pressure, temperature to inlet total temperature). Turn off the energy equation for the first 50 iterations. Leave the energy under-relaxation at 1. Set the pressure under-relaxation to 0.4, and the momentum under-relaxation to 0.3. After the solution stabilizes and the energy equation has been turned on, increase the pressure under-relaxation to 0.7.

- Set reasonable limits for the temperature and pressure (in the Solution Limits Dialog Box (p. 5112)) to avoid solution divergence, especially at the start of the calculation. If Ansys Fluent prints messages about temperature or pressure being limited as the solution nears convergence, the high or low computed values may be physical, and you must change the limits to allow these values.

- If required, begin the calculations using a reduced pressure ratio at the boundaries, increasing the pressure ratio gradually in order to reach the final desired operating condition. If the Mach number is low, you can also consider starting the compressible flow calculation from an incompressible flow solution (although the incompressible flow solution can in some cases be a rather poor initial guess for the compressible calculation).

- In some cases, computing an inviscid solution as a starting point may be helpful.

See Using the Solver (p. 3557) for details on the procedures used to make these changes to the solution parameters.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

9.4.6. Reporting of Results for Compressible Flows

You can display the results of your compressible flow calculations in the same manner that you would use for an incompressible flow. The variables listed below are of particular interest when you model compressible flow:

- **Total Temperature**
- **Total Pressure**
- **Mach Number**

These variables are contained in the variable selection drop-down list that appears in postprocessing dialog boxes. **Total Temperature** is in the **Temperature...** category, **Total Pressure** is in the **Pressure...** category, and **Mach Number** is in the **Velocity...** category. See Field Function Definitions (p. 4133) for their definitions.

9.5. Inviscid Flows

Inviscid flow analysis neglect the effect of viscosity on the flow and are appropriate for high-Reynolds-number applications where inertial forces tend to dominate viscous forces. One example for which an inviscid flow calculation is appropriate is an aerodynamic analysis of some high-speed projectile. In a case like this, the pressure forces on the body will dominate the viscous forces. Hence, an inviscid analysis will give you a quick estimate of the primary forces acting on the body. After the body shape has been modified to maximize the lift forces and minimize the drag forces, you can perform a viscous analysis to include the effects of the fluid viscosity and turbulent viscosity on the lift and drag forces.

Another area where inviscid flow analysis are routinely used is to provide a good initial solution for problems involving complicated flow physics and/or complicated flow geometry. In a case like this, the viscous forces are important, but in the early stages of the calculation the viscous terms in the momentum equations will be ignored. Once the calculation has been started and the residuals are decreasing, you can turn on the viscous terms (by enabling laminar or turbulent flow) and continue the solution to convergence. For some very complicated flows, this is the only way to get the calculation started.

Information about inviscid flows is provided in the following subsections:

9.5.1. Setting Up an Inviscid Flow Model
9.5.2. Solution Strategies for Inviscid Flows
9.5.3. Postprocessing for Inviscid Flows

For more information about the theoretical background of inviscid flows, see Inviscid Flows in the Theory Guide.

9.5.1. Setting Up an Inviscid Flow Model

For inviscid flow problems, you must perform the following steps during the problem setup procedure. (Only those steps relevant specifically to the setup of inviscid flow are listed here. You must set up the rest of the problem as usual.)

1. Enable the calculation of inviscid flow by selecting **Inviscid** in the Viscous Model Dialog Box (p. 4663).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setup → **Models** → **Viscous** → **Model** → **Inviscid**

2. Set boundary conditions and flow properties.

Setup → **Boundary Conditions**

> **Note:**
>
> Walls are assumed to be slip surfaces (the velocity is not equal to zero, unlike viscous flows) and therefore have a tangential velocity computed based on the solution of the governing equations.

Setup → **Materials**

3. Solve the problem and examine the results.

9.5.2. Solution Strategies for Inviscid Flows

Since inviscid flow problems will usually involve high-speed flow, you may have to reduce the under-relaxation factors for momentum (if you are using the pressure-based solver) or reduce the Courant number (if you are using the density-based solver), in order to get the solution started. Once the flow is started and the residuals are monotonically decreasing, you can start increasing the under-relaxation factors or Courant number back up to the default values.

Modifications to the under-relaxation factors and the Courant number can be made in the Solution Controls Task Page (p. 5109).

Solution → **Controls**

The solution strategies for compressible flows apply also to inviscid flows. See Solution Strategies for Compressible Flows (p. 1737) for details.

9.5.3. Postprocessing for Inviscid Flows

If you are interested in the lift and drag forces acting on your model, you can use the Force Reports Dialog Box (p. 5268) to compute them.

Results → **Reports** → **Forces** **Edit...**

See Forces on Boundaries (p. 4111) for details.

Chapter 10: Modeling Flows with Moving Reference Frames

This chapter provides details about the moving reference frame capabilities in Ansys Fluent.

The information in this chapter is divided into the following sections:

10.1. Introduction
10.2. Flow in Single Moving Reference Frames (SRF)
10.3. Flow in Multiple Moving Reference Frames

10.1. Introduction

Ansys Fluent solves the equations of fluid flow and heat transfer, by default, in a stationary (or inertial) reference frame. However, there are many problems where it is advantageous to solve the equations in a moving (or non-inertial) reference frame. Such problems typically involve moving parts (such as rotating blades, impellers, and similar types of moving surfaces), and it is the flow around these moving parts that is of interest. In most cases, the moving parts render the problem unsteady when viewed from the stationary frame. With a moving reference frame, however, the flow around the moving part can (with certain restrictions) be modeled as a steady-state problem with respect to the moving frame.

Ansys Fluent's moving reference frame modeling capability allows you to model problems involving moving parts by allowing you to enable moving reference frames in selected cell zones. When a moving reference frame is activated, the equations of motion are modified to incorporate the additional acceleration terms that occur due to the transformation from the stationary to the moving reference frame. By solving these equations in a steady-state manner, the flow around the moving parts can be modeled.

For many problems, it may be possible to refer the entire computational domain to a single moving reference frame. This is known as the single reference frame (or SRF) approach. The use of the SRF approach is possible; provided the geometry meets certain requirements. For more complex geometries, it may not be possible to use a single reference frame. In such cases, you must break up the problem into multiple cell zones, with well-defined interfaces between the zones. This is the multiple reference frame (or MRF) approach and is discussed in The Multiple Reference Frame Model (p. 1751). If unsteady interaction between the stationary and moving parts is important, you can employ the sliding mesh approach to capture the transient behavior of the flow. The sliding meshing model will be discussed in Modeling Flows Using Sliding and Dynamic Meshes (p. 1765).

The principal reason for employing a moving reference frame is to render a problem that is unsteady in the stationary (inertial) frame, steady with respect to the moving frame. For a steadily moving frame (for example, the frame speed is constant), it is possible to transform the equations of fluid motion to the moving frame such that steady-state solutions are possible. By default, Ansys Fluent permits the activation of a moving reference frame with a steady speed. If the speed is not constant, the transformed equations will contain additional terms (see Relative Velocity Formulation in the Theory Guide). It should also be noted that you can run an unsteady simulation in a moving reference frame with constant

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

speed. This would be necessary if you wanted to simulate, for example, vortex shedding from a rotating fan blade. The unsteadiness in this case is due to a natural fluid instability (vortex generation) rather than induced from interaction with a stationary component.

For more information about the equations for moving reference frames, see Equations for a Moving Reference Frame in the Theory Guide.

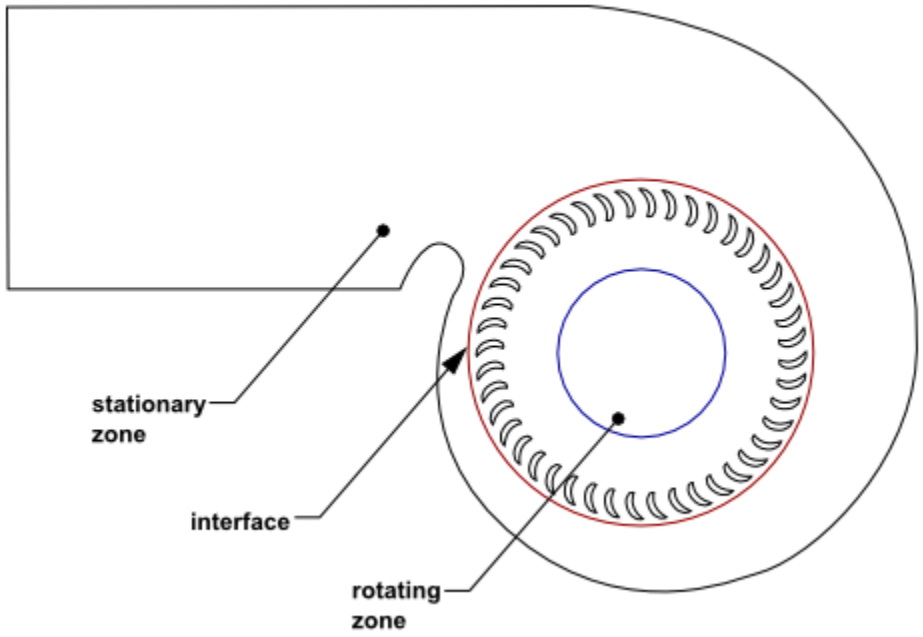
Figure 10.2: Multiple Component (Blower Wheel and Casing)



10.2. Flow in Single Moving Reference Frames (SRF)

Many problems permit the entire computational domain to be referred to a single moving reference frame (hence the name SRF modeling). In such cases, the equations given in Equations for a Moving Reference Frame are solved in all fluid cell zones. Steady-state solutions are possible in SRF models provided suitable boundary conditions are prescribed. In particular, wall boundaries must adhere to the following requirements:

- Any walls that are moving with the reference frame can assume any shape. An example would be the blade surfaces associated with a pump impeller. The no slip condition is defined in the relative frame such that the relative velocity is zero on the moving walls.
- For a rotating problem, you can define walls that are non-moving with respect to the stationary coordinate system, but these walls must be surfaces of revolution about the axis of rotation. Here the no slip condition is defined such that the absolute velocity is zero on the walls. An example of this type of boundary would be a cylindrical wind tunnel wall that surrounds a rotating propeller.

Rotationally periodic boundaries may also be used, but the surface must be periodic about the axis of rotation. As an example, it is very common to model flow through a blade row of a turbomachine by assuming the flow to be rotationally periodic and using a periodic domain about a single blade. This permits good resolution of the flow around the blade without the expense of modeling all blades in the blade row (see Figure 10.3: Single Blade Model with Rotationally Periodic Boundaries (p. 1744)).

Flow boundary conditions in Ansys Fluent (inlets and outlets) can, in most cases, be prescribed in either the stationary or moving frames. For example, for a velocity inlet, one can specify either the relative velocity or absolute velocity, depending on which is more convenient. For additional information on these and other boundary conditions, see Setting Up a Single Moving Reference Frame Problem (p. 1744) and Cell Zone and Boundary Conditions (p. 1277).

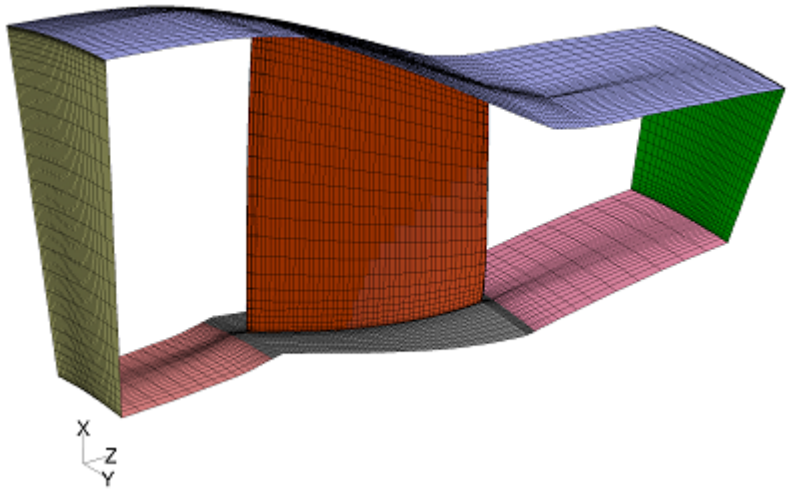
Figure 10.3: Single Blade Model with Rotationally Periodic Boundaries



10.2.1. Mesh Setup for a Single Moving Reference Frame

It is important to remember the following coordinate-system constraints when you are setting up a problem involving a moving reference frame for a rotating problem:

- For 2D problems, the axis of rotation must be parallel to the z axis.
- For 2D axisymmetric problems, the axis of rotation must be the x axis.
- For 3D geometries, you should generate the mesh with a specific origin and rotational axis in mind for the rotating cell zone. Usually it is convenient to use the origin of the global coordinate system (0,0,0) for the frame origin, and either the x, y, or z axis for the rotational axis; however, Ansys Fluent can accommodate an arbitrary origin and rotational axis.

With 3D rotating problems, it is also important to note that if you want to include walls that have zero velocity in the stationary frame, these walls must be a surface of revolution with respect to the axis of rotation. If the stationary walls are not surfaces of revolution, you must encapsulate the rotating parts with interface boundaries, thereby breaking your model up into multiple zones, and use the MRF model for a steady-state solution (see The Multiple Reference Frame Model (p. 1751)), or the sliding mesh model for unsteady interaction (see Modeling Flows Using Sliding and Dynamic Meshes (p. 1765)).

10.2.2. Setting Up a Single Moving Reference Frame Problem

To model a problem involving a single moving reference frame, follow the steps outlined below.

1. Select the **Velocity Formulation** to be used when solving: either **Relative** or **Absolute**. (See Choosing the Relative or Absolute Velocity Formulation (p. 1747) for details.)

   Setup → **General**

   (Note that this step is irrelevant if you are using one of the density-based solvers; these solvers always use an absolute velocity formulation.)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. For each cell zone in the domain, specify the translational velocity of the reference frame and/or the angular velocity (ω) of the reference frame and the axis about which it rotates.

   Setup → Cell Zone Conditions

   a. In the **Fluid** or **Solid** dialog box, specify the **Rotation-Axis Origin** and **Rotation-Axis Direction** for the frame motion in the **Reference Frame** tab, in order to define the axis of rotation.

   b. Also in the **Fluid** (Figure 10.4: The Fluid Dialog Box Displaying Frame Motion Inputs (p. 1746)) or **Solid** dialog box, enable the **Frame Motion** option. (Note that a solid zone cannot move at a different speed than an adjacent solid zone; for such a situation, you must instead use **Solid Motion**.)

      In the **Reference Frame** tab, set the **Speed** under **Rotational Velocity** and/or the **X**, **Y**, and **Z** components of the **Translational Velocity**. Note that the speed can be specified as a constant value or a transient profile. The transient profile may be in a file format, as described in Transient Cell Zone and Boundary Conditions (p. 1499), or a UDF macro, described in `DEFINE_TRANSIENT_PROFILE`. Specifying the individual velocities as either a profile or a UDF allows you to specify a specific input of the frame motion individually. However, you can also specify the frame motion inputs via a single user-defined function that uses the UDF macro `DEFINE_ZONE_MOTION`. This may prove to be quite convenient if you are modeling a more complicated motion of the moving reference frame, where the hooking of many different user-defined functions or profiles can be cumbersome.

      Note:

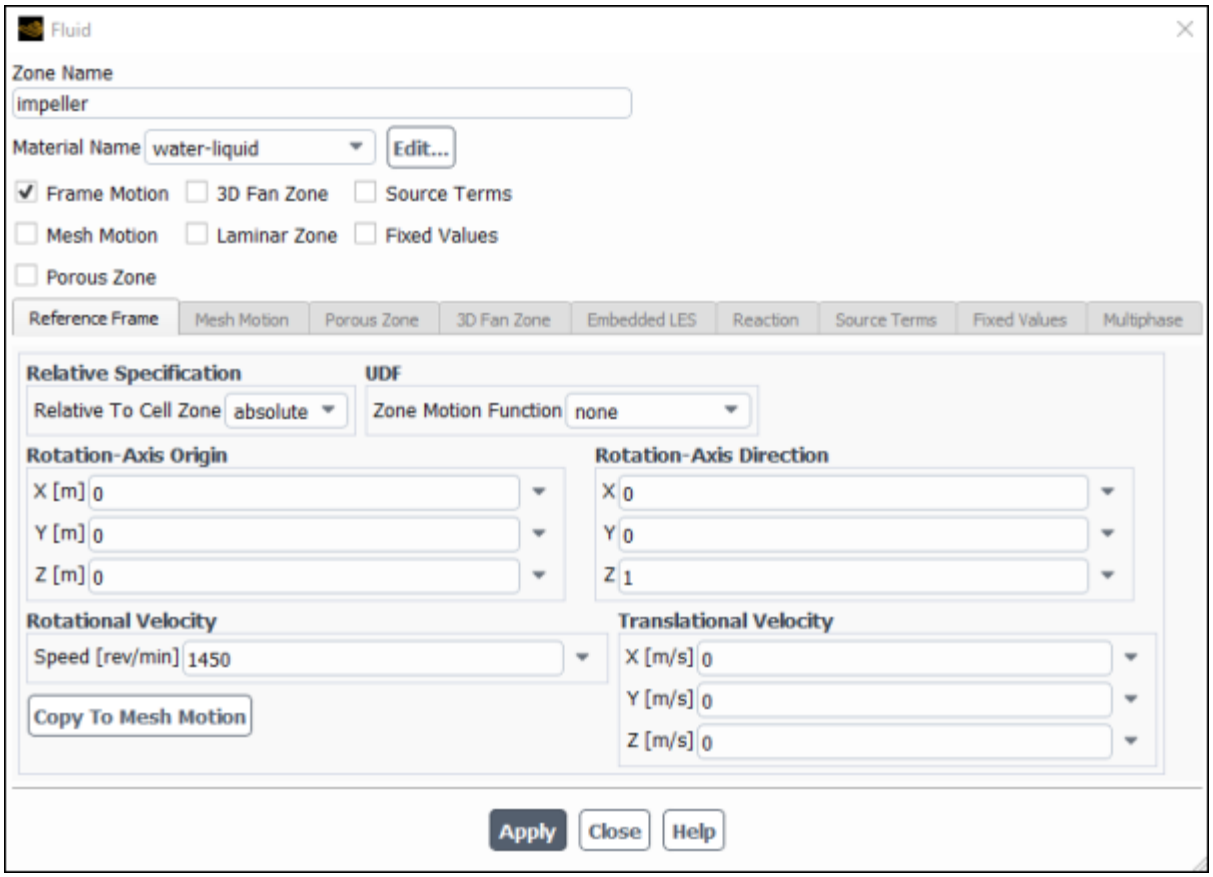
      If you decide to hook a UDF, you will no longer have access to the rotation axis origin and direction, or the velocities.

      Details about these inputs are presented in Inputs for Fluid Zones (p. 1299) and in Inputs for Solid Zones (p. 1305). Details about the zone motion UDF can be found in `DEFINE_ZONE_MOTION` in the Fluent Customization Manual.

   c. If you need to switch between the moving reference frame and moving mesh models, simply click the **Copy To Mesh Motion** for zones with a moving frame of reference and **Copy to Frame Motion** for zones with moving meshes to transfer motion variables, such as the axes, frame origin, and velocity components between the two models. The variables used for the origin, axis, and velocity components, as well as for the UDF `DEFINE_ZONE_MOTION` will be copied. This is particularly useful if you are doing a steady-state MRF simulation to obtain an initial solution for a transient Moving Mesh simulation in a turbomachine.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 10.4: The Fluid Dialog Box Displaying Frame Motion Inputs



Important:

Normally it is not necessary to enable the **Frame Motion** option for solid zones, as this is not required if you want to do a conjugate heat transfer problem where the solid and fluid zones are moving together. A case in which you would want to enable the **Frame Motion** option is if you are running an intrinsic fluid-structure-interaction (FSI) simulation, and you want the structural model to account for rotational forces when calculating the deformation of the solid cell zone (see Modeling Fluid-Structure Interaction (FSI) Within Fluent (p. 3219)).

3. Define the velocity boundary conditions at walls. You can choose to define either an absolute velocity or a velocity relative to the moving reference frame (that is, relative to the velocity of the adjacent cell zone specified in step 2).

   If the wall is moving at the speed of the moving frame (and hence stationary in the moving frame), it is convenient to specify a relative angular velocity of zero. Likewise, a wall that is stationary in the non-moving frame of reference should be given a velocity of zero in the absolute reference frame. Specifying the wall velocities in this manner obviates the need to modify these inputs later if a change is made in the velocity of the fluid zone.

   Details about these inputs are presented in Velocity Conditions for Moving Walls (p. 1440).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Define the boundary conditions at the inlets, as described in Boundary Conditions (p. 1370). For velocity inlets, you can choose to define either absolute velocities or velocities relative to the motion of the adjacent cell zone (specified in step 2). Likewise, the total pressure and flow direction can be prescribed in absolute or relative frames for pressure inlets.

   Details about these inputs are presented in Defining the Flow Direction (p. 1383) and Defining the Velocity (p. 1391).

10.2.2.1. Choosing the Relative or Absolute Velocity Formulation

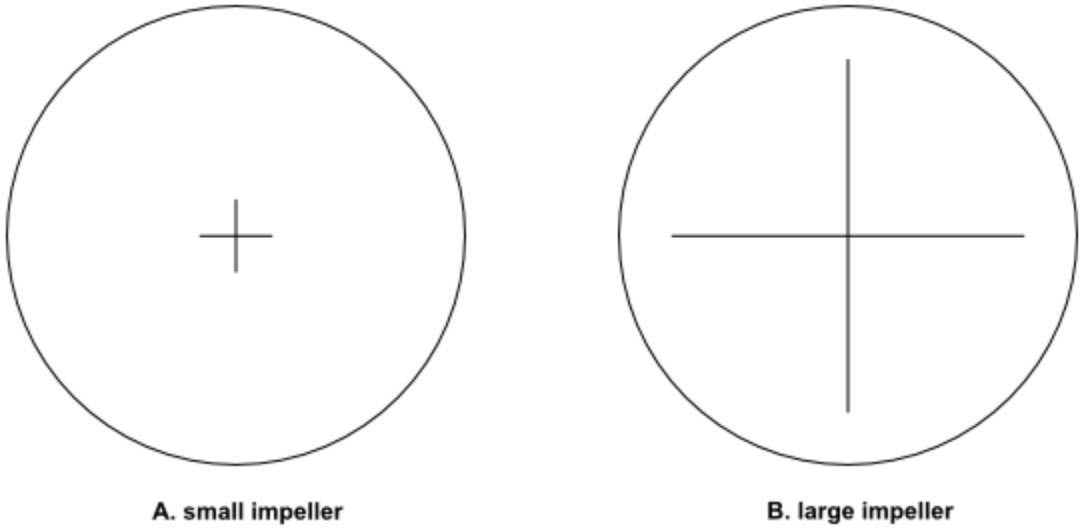
It is recommended that you use the velocity formulation that will result in most of the flow domain having the smallest velocities in that frame, thereby reducing the numerical diffusion in the solution and leading to a more accurate solution.

The absolute velocity formulation is preferred in applications where the flow in most of the domain is not moving (for example, a fan in a large room). The relative velocity formulation is appropriate when most of the fluid in the domain is moving, as in the case of a large impeller in a mixing tank.

10.2.2.1.1. Example

A problem with stationary outer walls and a rotating impeller can be solved in a single reference frame. The example is illustrated in Figure 10.5: Geometry with the Rotating Impeller (p. 1747).

Figure 10.5: Geometry with the Rotating Impeller



In case A, it is expected that only the flow near the impeller would be rotating and that much of the flow away from the impeller would have a low velocity magnitude in the absolute frame. Therefore, solving using the absolute velocity formulation is recommended. In case B, most of the flow is expected to be rotating with a velocity close to that of the impeller. Hence, the relative velocity formulation is appropriate.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In a situation between case A and case B, either of the formulations may be used.

Important:

- If the velocity formulation is switched during the solution process, Ansys Fluent will not transform the current solution to the other frame, which can lead to large jumps in residuals. If changing the frame is necessary, it is recommended that you first reinitialize, and then solve.
- When one of the density-based solution algorithms is used, the absolute formulation is always used; the relative velocity formulation is not available in the density-based solvers.

For velocity inlets, pressure inlets, mass-flow inlets, and walls, you may specify velocity in either the absolute or the relative frame, regardless of whether the absolute or relative velocity formulation is used in the computation. Note, that the inlet turbulence values are processed using the velocity values, which are converted to the Velocity Formulation selected in the General Task Page (p. 4632), see explanations in Estimating Turbulent Kinetic Energy from Turbulence Intensity (p. 1376) and in the introductory part of Inlet Boundary Conditions for Scale Resolving Simulations.

For pressure outlets, the specified static pressure is independent of frame. However, when there is backflow at a pressure outlet, the specified static pressure is used as the total pressure. For calculations using the absolute velocity formulation, the specified static pressure is used as the total pressure in the absolute frame; for the relative velocity formulation, the specified static pressure is assumed to be the total pressure in the relative frame. As for the flow direction, Ansys Fluent assumes the absolute velocity to be normal to the pressure outlet for the absolute velocity formulation; for the relative velocity formulation, it is the relative velocity that is assumed to be normal to the pressure outlet.

10.2.3. Solution Strategies for a Single Moving Reference Frame

The difficulties associated with solving flows in moving reference frames are similar to those discussed in Solution Strategies for Axisymmetric Swirling Flows (p. 1729). The primary issue you must confront is the high degree of coupling between the momentum equations when the influence of the rotational terms is large. A high degree of rotation introduces a large radial pressure gradient that drives the flow in the axial and radial directions, thereby setting up a distribution of the swirl or rotation in the field. This coupling may lead to instabilities in the solution process, and hence require special solution techniques to obtain a converged solution. Some techniques that may be beneficial include the following:

- (Pressure-based solver only) Consider switching the frame in which velocities are solved by changing the velocity formulation setting in the General Task Page (p. 4632). (See Choosing the Relative or Absolute Velocity Formulation (p. 1747) for details.)
- (Pressure-based segregated solver only) Use the PRESTO! scheme (enabled in the Solution Methods Task Page (p. 5103)), which is well-suited for the steep pressure gradients involved in rotating flows.
- Ensure that the mesh is sufficiently refined to resolve large gradients in pressure and swirl velocity.
- (Pressure-based, segregated solver only) Reduce the under-relaxation factors for the velocities, perhaps to 0.3–0.5 or lower, if necessary.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Begin the calculations using a low rotational speed, increasing the rotational speed gradually in order to reach the final desired operating condition.

See Using the Solver (p. 3557) for details on the procedures used to make these changes to the solution parameters.

10.2.3.1. Gradual Increase of the Rotational Speed to Improve Solution Stability

Because the rotation of the reference frame and the rotation defined via boundary conditions can lead to large complex forces in the flow, your Ansys Fluent calculations may be less stable as the speed of rotation (and hence the magnitude of these forces) increases. One of the most effective controls you can exert on the solution is to start with a low rotational speed and then slowly increase the rotation up to the desired level. The procedure you use to accomplish this is as follows:

1. Set up the problem using a low rotational speed in your inputs for boundary conditions and for the angular velocity of the reference frame. The rotational speed in this first attempt might be selected as 10% of the actual operating condition.

2. Solve the problem at these conditions.

3. Save this initial solution data.

4. Modify your inputs (that is, boundary conditions and angular velocity of the reference frame). Increase the speed of rotation, perhaps doubling it.

5. Restart or continue the calculation using the solution data saved in Step 3 as the initial guess for the new calculation. Save the new data.

6. Continue to increment the rotational speed, following Steps 4 and 5, until you reach the desired operating condition.

10.2.4. Postprocessing for a Single Moving Reference Frame

When you solve a problem in a moving reference frame, you can plot or report both absolute and relative velocities. For all velocity parameters (for example, **Velocity Magnitude** and **Mach Number**), corresponding relative values will be available for postprocessing (for example, **Relative Velocity Magnitude** and **Relative Mach Number**). These variables are contained in the **Velocity...** category of the variable selection drop-down list that appears in postprocessing dialog boxes. Relative values are also available for postprocessing of total pressure, total temperature, and any other parameters that include a dynamic contribution dependent on the reference frame (for example, **Relative Total Pressure**, **Relative Total Temperature**, **Rothalpy**).

When plotting velocity vectors, you can choose to plot vectors in the absolute frame (the default), or you can select **Relative Velocity** in the **Vectors of** drop-down list in the Vectors Dialog Box (p. 5597) to plot vectors in the moving frame. If you plot relative velocity vectors, you might want to color the vectors by relative velocity magnitude (by choosing **Relative Velocity Magnitude** in the **Color by** list); by default they will be colored by absolute velocity magnitude. Figure 10.6: Absolute Velocity Vectors (p. 1750) and Figure 10.7: Relative Velocity Vectors (p. 1750) show absolute and relative velocity vectors in a moving domain with a stationary outer wall.

10.3. Flow in Multiple Moving Reference Frames

Many problems involve multiple moving parts or contain stationary surfaces which are not surfaces of revolution (and therefore cannot be used with the Single Reference Frame modeling approach). For these problems, you must break up the model into multiple fluid/solid cell zones, with interface boundaries separating the zones. Zones that contain the moving components can then be solved using the moving reference frame equations (Equations for a Moving Reference Frame in the Theory Guide), whereas stationary zones can be solved with the stationary frame equations.

- Multiple Reference Frame Model (MRF)
- Sliding Mesh Model (SMM)

The MRF is a steady-state approximation whereas the SMM approach is inherently unsteady due to the motion of the mesh with time. This approach is discussed in Modeling Flows Using Sliding and Dynamic Meshes (p. 1765).

For additional information, see the following sections:

10.3.1. The Multiple Reference Frame Model
10.3.2. Mesh Setup for a Multiple Moving Reference Frame
10.3.3. Setting Up a Multiple Moving Reference Frame Problem
10.3.4. Solution Strategies for MRF and Problems
10.3.5. Postprocessing for MRF Problems

10.3.1. The Multiple Reference Frame Model

Additional information about the MRF model is presented in the following sections:

10.3.1.1. Overview
10.3.1.2. Limitations

10.3.1.1. Overview

The MRF model [89] (p. 5660) is, perhaps, the simplest of the two approaches for multiple zones. It is a steady-state approximation in which individual cell zones can be assigned different rotational and/or translational speeds. The flow in each moving cell zone is solved using the moving reference frame equations (see Introduction (p. 1741)). If the zone is stationary (ω=0), the equations reduce to their stationary forms. At the interfaces between cell zones, a local reference frame transformation is performed to enable flow variables in one zone to be used to calculate fluxes at the boundary of the adjacent zone. For more information about the MRF interface formulation, see The MRF Interface Formulation in the Theory Guide.

It should be noted that the MRF approach does not account for the relative motion of a moving zone with respect to adjacent zones (which may be moving or stationary); the mesh remains fixed for the computation. This is analogous to freezing the motion of the moving part in a specific position and observing the instantaneous flowfield with the rotor in that position. Hence, the MRF is often referred to as the "frozen rotor approach."

While the MRF approach is clearly an approximation, it can provide a reasonable model of the flow for many applications. For example, the MRF model can be used for turbomachinery applications

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

in which rotor-stator interaction is relatively weak, and the flow is relatively uncomplicated at the interface between the moving and stationary zones. In mixing tanks, for example, since the impeller-baffle interactions are relatively weak, large-scale transient effects are not present and the MRF model can be used.

Another potential use of the MRF model is to compute a flow field that can be used as an initial condition for a transient sliding mesh calculation. This eliminates the need for a startup calculation. The multiple reference frame model should not be used, however, if it is necessary to actually simulate the transients that may occur in strong rotor-stator interactions, the sliding mesh model alone should be used (see Modeling Flows Using Sliding and Dynamic Meshes (p. 1765).

For more information about and examples of multiple moving reference frames, see The Multiple Reference Frame Model in the Theory Guide.

10.3.1.2. Limitations

The following limitations exist when using the MRF approach:

- The interfaces separating a moving region from adjacent regions must be oriented such that the component of the frame velocity normal to the boundary is zero. This means that for a translationally moving frame, the moving zone's boundaries must be parallel to the translational velocity vector. For rotating problems, the interfaces must be surfaces of revolution about the axis of rotation defined for the fluid zone. For the example shown Figure 2.4: Geometry with One Rotating Impeller (in the Theory Guide), this requires the dashed boundary to be circular (not square or any other shape).

- Strictly speaking, the use of multiple reference frames is meaningful only for steady flow. However, Ansys Fluent will allow you to solve an unsteady flow when multiple reference frames are being used. In this case, unsteady terms (as described in Temporal Discretization in the Theory Guide) are added to all the governing transport equations. You should carefully consider whether this will yield meaningful results for your application, because, for unsteady flows, a sliding mesh calculation will generally yield more meaningful results than an MRF calculation.

- By default, pathlines and particle trajectories drawn by Ansys Fluent use the velocity relative to the reference frame motion of the cell zone. However, for particle trajectories, you can change the reference frame by either selecting **Track in Absolute Frame** in the **Numerics** tab of the **Discrete Phase Model** dialog box or using the text command `define/models/dpm/options/track-in-absolute-frame`.

  Note:

  When a pathline or particle trajectory crosses a boundary between zones with different reference frame motion specifications, you may observe a sharp change in particle velocity as a result of the coordinate transformation.

  The particle injection velocities (specified in the Set Injection Properties Dialog Box (p. 5550)) are interpreted in the same way as tracking, that is, either relative to the local frame of reference's motion specification or in absolute coordinates.

- You cannot accurately model axisymmetric swirl in the presence of multiple reference frames using the relative velocity formulation. This is because the current implementation does not apply

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the transformation used in Equation 2.16 (in the Theory Guide) to the swirl velocity derivatives. For this situation, the absolute velocity formulation should be used.

- Translational and rotational velocities are assumed to be constant (time varying ω, v_t are not allowed).
- The relative velocity formulation cannot be used in combination with the MRF and mixture models. (For details, see Mixture Model Theory in the Theory Guide). For such cases, use the absolute velocity formulation instead.
- You must not have a single interface between reference frames where part of the interface is made up of a coupled two-sided wall, while another part is not coupled (that is, the normal interface treatment). In such cases, you must break the interface up into two interfaces: one that is a coupled interface, and the other that is a standard fluid-fluid interface. See Using a Non-Conformal Mesh in Ansys Fluent (p. 1164) for the steps involved in setting up a coupled interface.

Important:

You can switch from the MRF model to the sliding mesh model for a more robust and accurate solution, by using the `mesh/modify-zones/mrf-to-sliding-mesh` text command. See Using Sliding Meshes (p. 1772) for details on how to make this change in the fluid's boundary conditions.

10.3.2. Mesh Setup for a Multiple Moving Reference Frame

Two mesh setup methods are available. Choose the method that is appropriate for your model, noting the restrictions in Limitations (p. 1752).

- If the boundary between two zones that are in different reference frames is conformal (that is, the mesh node locations are identical at the boundary where the two zones meet), you can simply create the mesh as usual, with all cell zones contained in the same mesh file. A different cell zone should exist for each portion of the domain that is modeled in a different reference frame. Use an *interior* zone for the boundary between reference frames.
- If the boundary between two zones that are in different reference frames is non-conformal (that is, the mesh node locations are *not* identical at the boundary where the two zones meet), follow the non-conformal mesh setup procedure described in Using a Non-Conformal Mesh in Ansys Fluent (p. 1164).

10.3.3. Setting Up a Multiple Moving Reference Frame Problem

To learn more about setting up a multiple reference frame problem, see the following sections:

10.3.3.1. Setting Up Multiple Reference Frames

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

10.3.3.1. Setting Up Multiple Reference Frames

To model a problem involving multiple reference frames, perform the following:

Important:

The mesh-setup constraints for a moving reference frame listed in Mesh Setup for a Single Moving Reference Frame (p. 1744) apply to multiple reference frames as well.

1. Select the **Velocity Formulation** to be used in the General Task Page (p. 4632): either **Absolute** or **Relative**. (For details, see Choosing the Relative or Absolute Velocity Formulation (p. 1747).)

   Setup → General

   (Note that this step is irrelevant if you are using one of the density-based solution algorithms; these algorithms always use an absolute velocity formulation.)

2. For each cell zone in the domain, specify its translational velocity and/or its angular velocity (ω) and the axis about which it rotates.

   Setup → Cell Zone Conditions

   a. If the zone is moving, or if you plan to specify cylindrical velocity or flow-direction components at inlets to the zone, you must define the axis of rotation of the frame of reference. In the **Fluid** or **Solid** dialog box, specify the **Rotation-Axis Origin** and **Rotation-Axis Direction** under the **Reference Frame** tab.

   b. In the **Fluid** (Figure 10.4: The Fluid Dialog Box Displaying Frame Motion Inputs (p. 1746)) or **Solid** dialog box, enable the **Frame Motion** option. (Note that a solid zone cannot move at a different speed than an adjacent solid zone; for such a situation, you must instead use **Solid Motion**.)

      In the **Reference Frame** tab, set the **Speed** under **Rotational Velocity** and/or the **X**, **Y**, and **Z** components of the **Translational Velocity**. Note that the speed can be specified as a constant value or a transient profile. The transient profile may be in a file format, as described in Transient Cell Zone and Boundary Conditions (p. 1499), or a UDF macro, described in `DEFINE_TRANSIENT_PROFILE`. Specifying the individual velocities as either a profile or a UDF allows you to specify a specific input of the frame motion individually. However, you can also specify the frame motion inputs via a single user-defined function that uses the UDF macro `DEFINE_ZONE_MOTION`. This may prove to be quite convenient if you are modeling a more complicated motion of the moving reference frame, where the hooking of many different user-defined functions or profiles can be cumbersome.

      Note:

      If you decide to hook a UDF, then you will no longer have access to the rotation axis origin and direction, or the velocities.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Details about these inputs are presented in Inputs for Fluid Zones (p. 1299) and in Inputs for Solid Zones (p. 1305). Details about the zone motion UDF can be found in `DEFINE_ZONE_MOTION` in the Fluent Customization Manual.

c. To switch between the MRF and moving mesh models, click the **Copy To Mesh Motion** for zones with a moving frame of reference and **Copy to Frame Motion** for zones with moving meshes to transfer motion variables, such as the axes, frame origin, and velocity components between the two models.

The variables used for the origin, axis, and velocity components, as well as for the UDF `DEFINE_ZONE_MOTION` will be copied. This is particularly useful if you are doing a steady-state MRF simulation to obtain an initial solution for a transient Moving Mesh simulation in a turbomachine.

3. Define the velocity boundary conditions at walls. You can choose to define either an absolute velocity or a velocity relative to the velocity of the adjacent cell zone specified in step 2.

If the wall is moving at the speed of the moving frame (and hence stationary relative to the moving frame), it is convenient to specify a relative angular velocity of zero. Likewise, a wall that is stationary in the non-moving frame of reference should be given a velocity of zero in the absolute reference frame. Specifying the wall velocities in this manner obviates the need to modify these inputs later if a change is made in the rotational velocity of the fluid zone.

An example for which you would specify a relative velocity is as follows: If an impeller is defined as **wall-3** and the fluid region within the impeller's radius is defined as **fluid-5**, you would need to specify the angular velocity and axis of rotation for **fluid-5** and then assign **wall-3** a relative velocity of 0. If you later wanted to model a different angular velocity for the impeller, you would need to change only the angular velocity of the fluid region; you would not need to modify the wall velocity conditions.

Details about these inputs are presented in Velocity Conditions for Moving Walls (p. 1440).

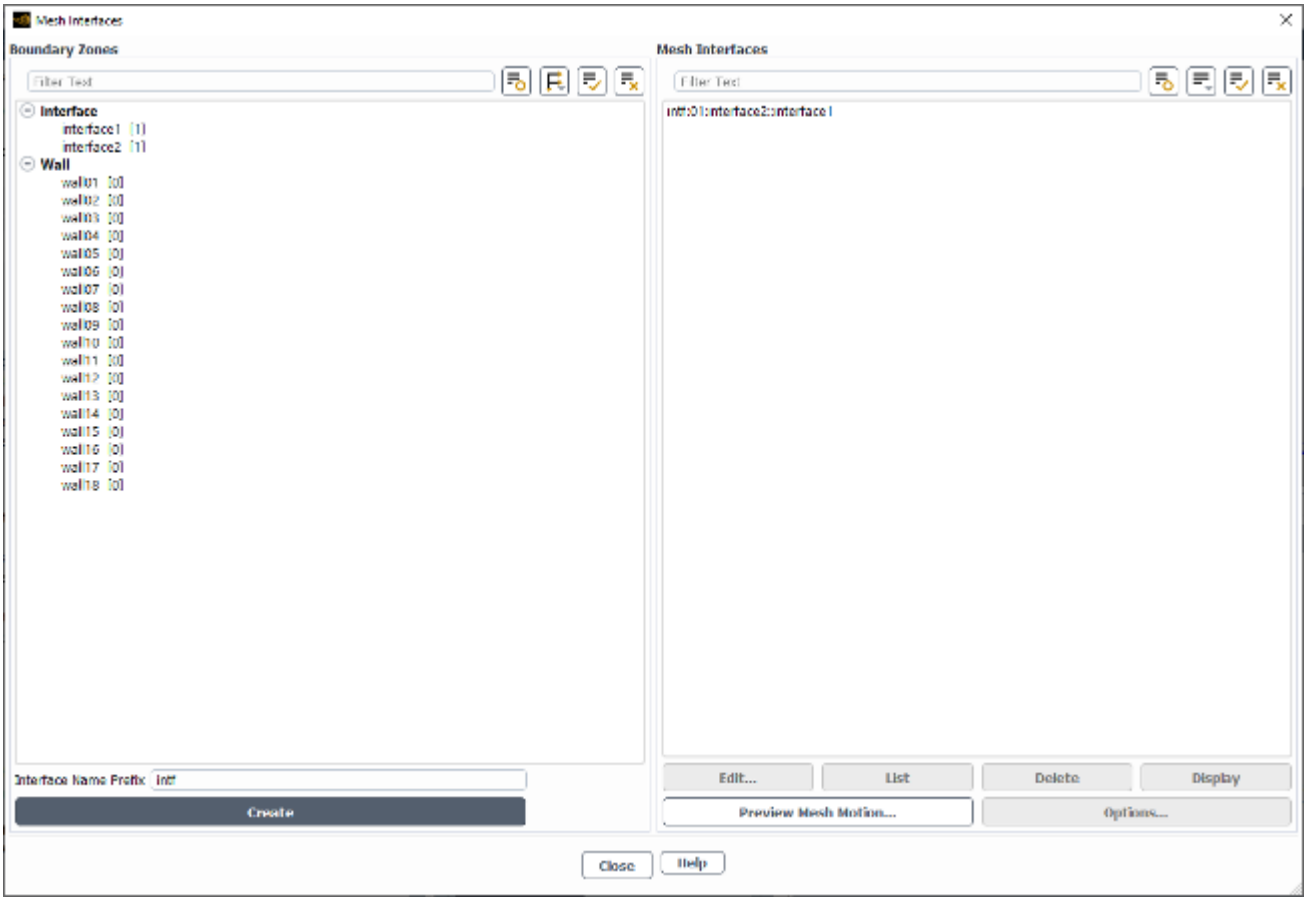
4. Define the boundary conditions at the inlets, as described in Boundary Conditions (p. 1370). For velocity inlets, you can choose to define either absolute velocities or velocities relative to the motion of the adjacent cell zone (specified in step 2). Likewise, the total pressure and flow direction can be prescribed in absolute or relative frames for pressure inlets.

Details about these inputs are presented in Defining the Flow Direction (p. 1383) and Defining the Velocity (p. 1391).

5. Define the mesh interfaces using the Mesh Interfaces Dialog Box (p. 5468) (Figure 12.10: The Mesh Interfaces Dialog Box (p. 1775)).

Setup → Mesh Interfaces → New...

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



To learn how to use the **Mesh Interfaces** dialog box, see Using a Non-Conformal Mesh in Ansys Fluent (p. 1164).

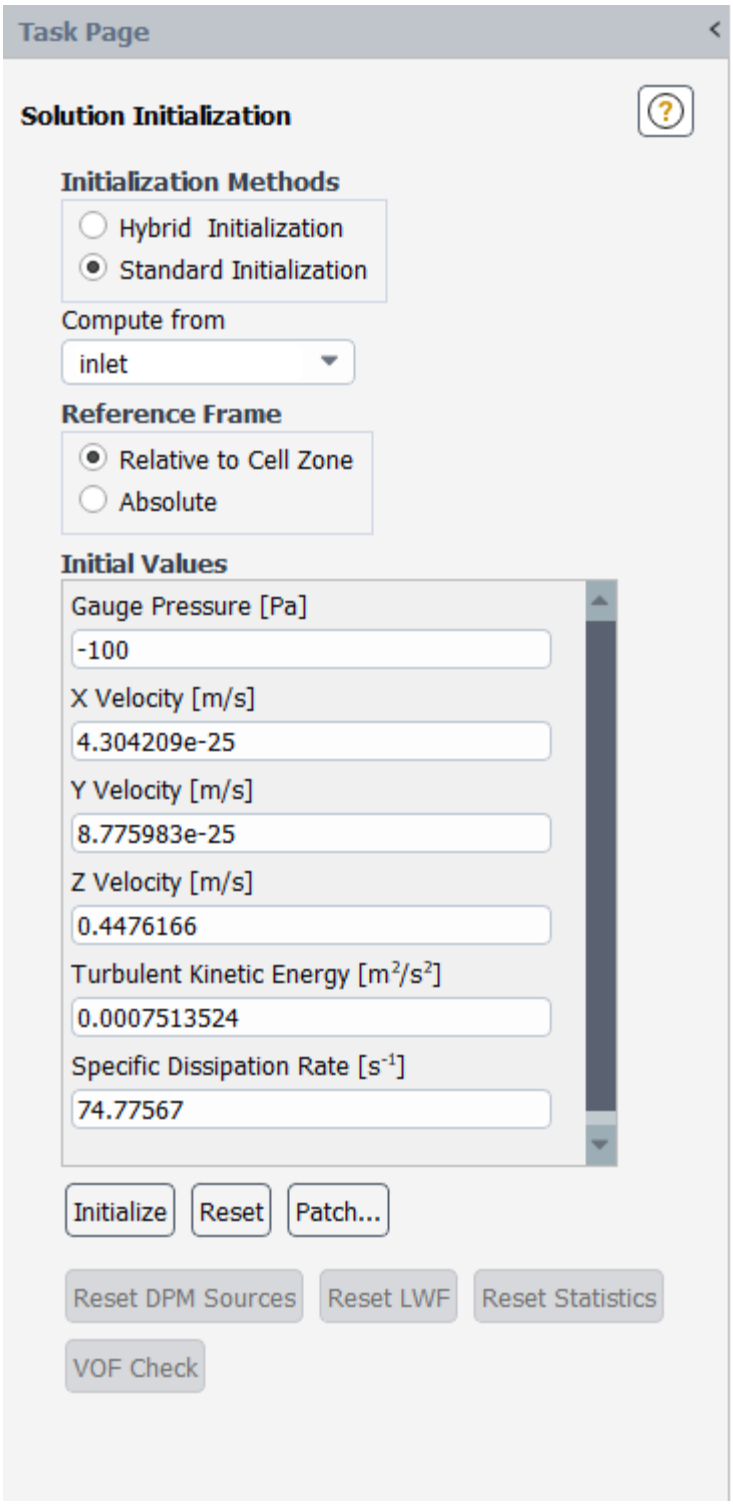
6. Initialize the solution using an absolute frame of reference (Figure 10.8: The Solution Initialization Task Page for Moving Reference Frames (p. 1757)).

   Solution → **Initialization**

   Select the **Absolute** option under **Reference Frame**. If the **Relative to Cell Zone** option is selected, the initial flow field can contain discontinuities, which can cause convergence problems in the first few iterations.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 10.8: The Solution Initialization Task Page for Moving Reference Frames



10.3.4. Solution Strategies for MRF and Problems

For multiple moving reference frames, follow the guidelines presented in Solution Strategies for a Single Moving Reference Frame (p. 1748) for a single moving reference frame. Remember that with multiple zones, the possibility exists of interaction between moving and stationary components. This

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

will manifest itself as poor or oscillatory convergence. In such cases, it is strongly recommend that the sliding mesh approach be used to compute the flowfield in order to resolve the unsteady interactions.

10.3.5. Postprocessing for MRF Problems

When you solve a problem using the multiple reference frame model, you can plot or report both absolute and relative velocities. For all velocity parameters (for example, **Velocity Magnitude** and **Mach Number**), corresponding relative values will be available for postprocessing (for example, **Relative Velocity Magnitude** and **Relative Mach Number**). These variables are contained in the **Velocity...** category of the variable selection drop-down list that appears in postprocessing dialog boxes. Relative values are also available for postprocessing of total pressure, total temperature, and any other parameters that include a dynamic contribution dependent on the reference frame (for example, **Relative Total Pressure**, **Relative Total Temperature**).

Important:

Relative velocities are relative to the translational/rotational velocity of the "reference zone" (specified in the **Reference Values** task page (see Reference Values Task Page (p. 5100))). The velocity of the reference zone is the velocity defined in the Fluid Dialog Box (p. 4909) for that zone.

When plotting velocity vectors, you can choose to plot vectors in the absolute frame (the default), or you can select **Relative Velocity** in the **Vectors of** drop-down list in the Vectors Dialog Box (p. 5597) to plot vectors relative to the translational/rotational velocity of the "reference zone" (specified in the Reference Values Task Page (p. 5100)). If you plot relative velocity vectors, you might want to color the vectors by relative velocity magnitude (by choosing **Relative Velocity Magnitude** in the **Color by** list); by default they will be colored by absolute velocity magnitude.

You can also generate a plot of circumferential averages in Ansys Fluent. This allows you to find the average value of a quantity at several different radial or axial positions in your model. Ansys Fluent computes the average of the quantity over a specified circumferential area, and then plots the average against the radial or axial coordinate. For more information on generating XY plots of circumferential averages, see XY Plots of Circumferential Averages (p. 4035).

For details about turbomachinery-specific postprocessing features, see Turbomachinery Postprocessing (p. 1997).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Chapter 11: Managing Auxiliary Geometry Definitions

This chapter describes how to create and manage auxiliary geometry definitions, which can be useful for the following:

- boundary adaption with the default polyhedral unstructured mesh adaption (PUMA) method (as described in Refining and Coarsening (p. 3759))

  When performing PUMA adaption on a surface, you can specify that the new nodes that are created are projected onto a geometry definition, so that the resulting mesh better conforms to the geometry shape. For more information about the concept of geometry-based adaption, see Geometry-Based Adaption in the Theory Guide.

- deforming dynamic mesh zones (as described in Deforming Motion (p. 1878))

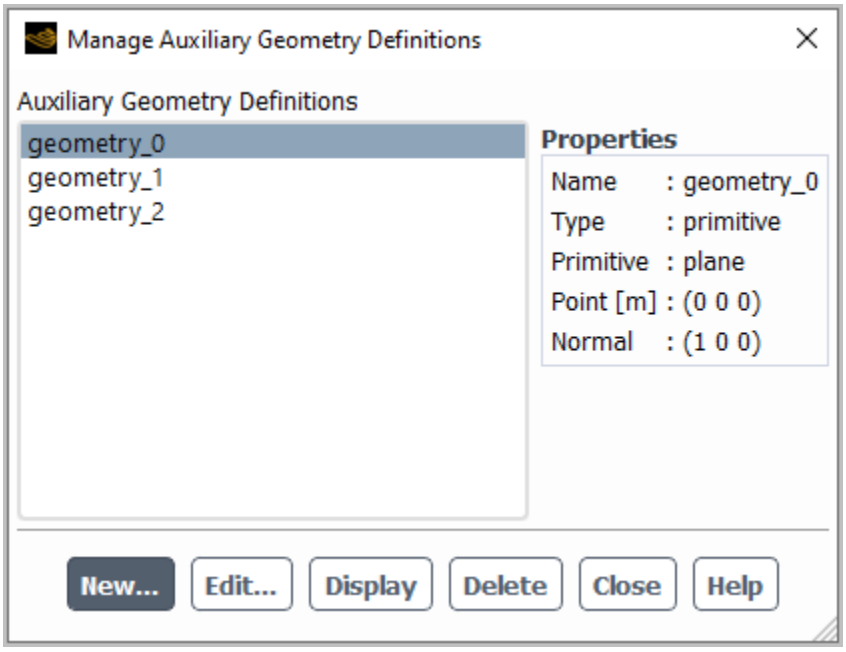
  You can specify that the nodes of the deforming mesh are projected onto an auxiliary geometry definition. This may simplify your setup, as the auxiliary geometry definitions provide shapes that are otherwise not available for deforming zones except through user-defined functions.

To manage auxiliary geometry, perform the following steps:

1. Open the **Manage Auxiliary Geometry Definitions** dialog box from the **Outline View**.

   Setup → Auxiliary Geometry Definitions → Manage...

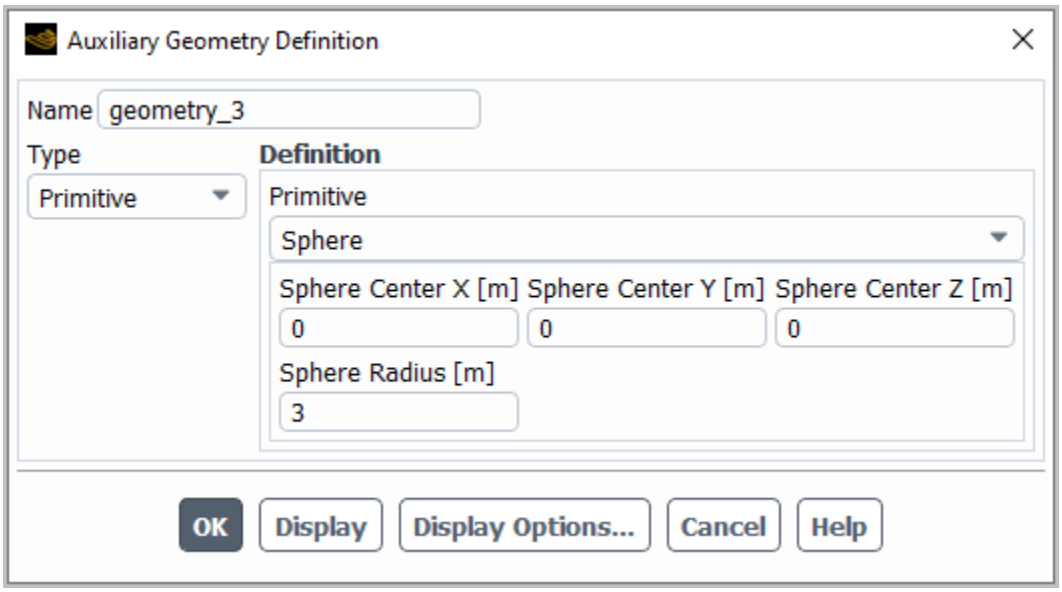
   Figure 11.1: The Manage Auxiliary Geometry Definitions Dialog Box



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Click the **New...** button in the **Manage Auxiliary Geometry Definitions** dialog box to open the **Auxiliary Geometry Definition** dialog box.

Figure 11.2: The Auxiliary Geometry Definition Dialog Box



a. Enter a suitable **Name** for the definition.

b. Make a selection from the **Type** drop-down list to specify how you will define the geometry. You have the following options:

- **Primitive**

  This allows you to make a selection from the **Primitive** drop-down list in the **Definition** group box. You can choose to define the geometry as a **Cone**, **Plane**, **Sphere**, **Frustum** (of a cone), or **Cylinder**. Then you must define the geometry using the other settings in the **Definition** group box.

Note:

– For the **Frustum** definition, the **Lower Radius** is defined for the end at the **Frustum Origin** coordinates, and the **Upper Radius** is defined for the opposite end.

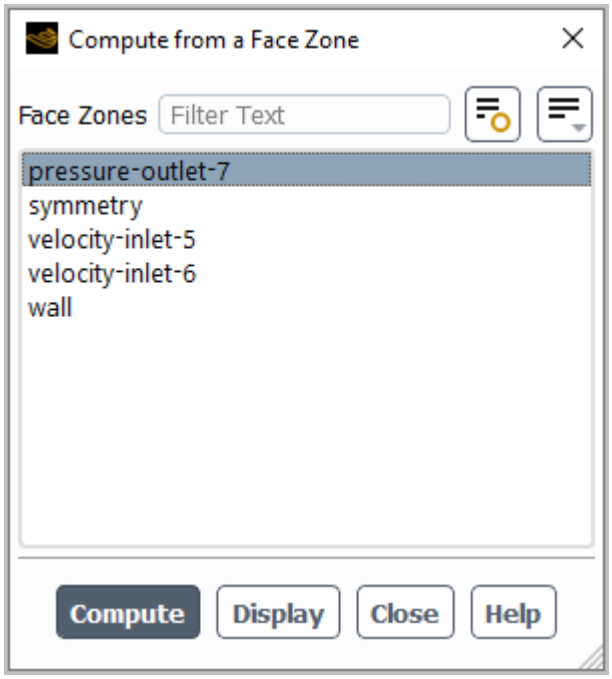
– The geometry definition for the **Frustum** and **Cylinder** only includes the curved surfaces, that is, it does not include the circular planar faces on the ends. To create a geometry definition for the ends, you would need to create additional definitions of **Plane** primitives.

– For the **Plane** definition, an easy way to define it is to click the **Compute from a Face Zone...** button; then in the **Compute from a Face Zone** dialog box that opens, select a face zone that is planar from the list and click the **Compute** button, and the fields in the **Auxiliary Geometry Definition** will be automatically filled. Note that after you select a zone in the **Compute from a Face Zone** dialog box,

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

you have the option of clicking the **Display** button to verify that you have selected the intended zone.

Figure 11.3: The Compute from a Face Zone Dialog Box



- **User-Defined**

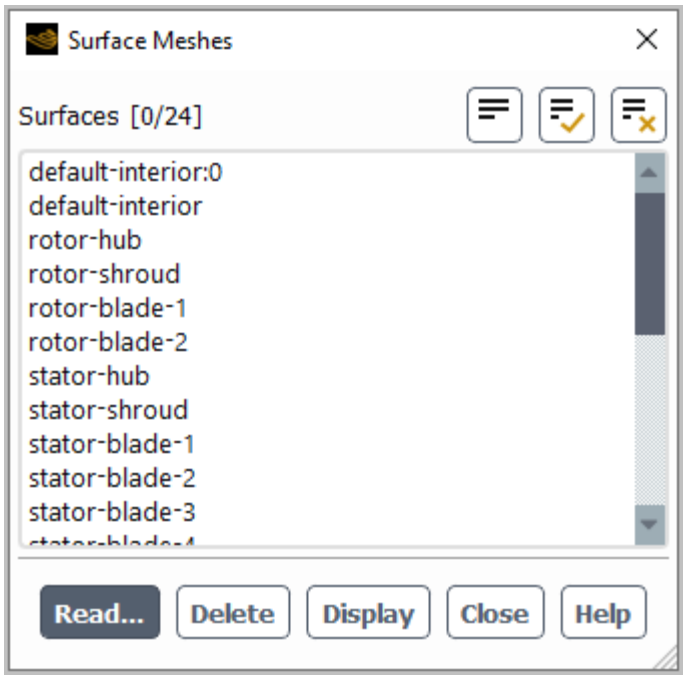
  This allows you to define the geometry by a user-defined function (UDF) that you have previously compiled. Select the UDF from the **Function** drop-down list in the **Definition** group box. Note that the UDF must use the `DEFINE_GEOMETRY` macro, as described in `DEFINE_GEOMETRY` in the *Fluent Customization Manual*.

- **Surface Mesh**

  This allows you to define the geometry using a surface zone from a separate mesh file. Click the **Surfaces Meshes...** button; then in the **Surfaces Meshes** dialog box that opens, click the **Read...** button, select a case, mesh, or STL file in the **Select File** dialog box that opens (being sure to select the units that the **Mesh was created in**), and close the **Surfaces Meshes** dialog box. Finally, specify the surface zone you want to define the geometry by making a selection from the **Background Mesh** drop-down in the **Auxiliary Geometry Definition** dialog box. For more information about reading surface meshes, see Reading Surface Mesh Files (p. 1138).

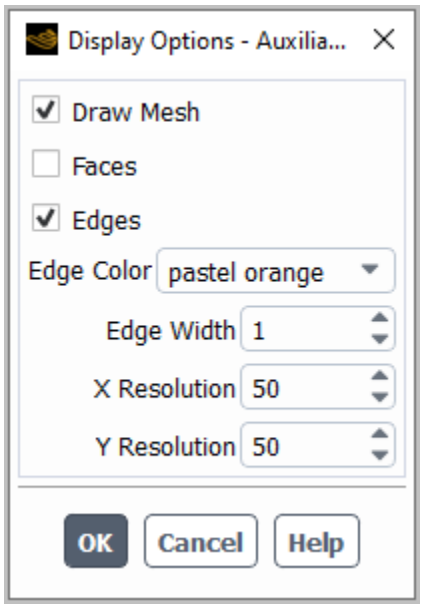
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 11.4: The Surfaces Meshes Dialog Box



c. You can verify that your geometry is appropriately defined by clicking the **Display** button and viewing it in the graphics window. If necessary, you can alter how it is displayed by clicking the **Display Options...** button and revising the setup in the **Display Options - Auxiliary Geometry Definitions** dialog box that opens.

Figure 11.5: The Display Options - Auxiliary Geometry Definitions Dialog Box



The settings for the **Display Options - Auxiliary Geometry Definitions** dialog box are the following:

- **Draw Mesh**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

toggles the ability to draw the mesh at the same time that the geometry definition is displayed. Enabling this option opens the Mesh Display Dialog Box (p. 4636), which allows you to select the desired surface or zone meshes to be displayed.

- **Faces**

  enables the display of shaded faces for the geometry definition. The color of the faces are specified using the **Face Color** drop-down list.

- **Edges**

  enables the display of edges for the geometry definition. The color of the edges are specified using the **Edge Color** drop-down list, and the thickness of the edges is specified through the **Edge Thickness** field.

- **X Resolution** and **Y Resolution**

  These set the number of faces into which the curved surface of a primitive shape is discretized; higher values results in a higher resolution. The **X Resolution** defines the discretization along the length direction or (for a **Sphere**) the z-direction, while the **Y Resolution** defines it around the circumference or (for a **Sphere**) the longitude.

d. Click **OK** to save your settings and close the **Auxiliary Geometry Definition** dialog box.

3. Repeat the previous step to add additional auxiliary geometry definitions.

4. After you have created auxiliary geometry definitions, you can use the **Manage Auxiliary Geometry Definitions** dialog box to take further actions. If you select a definition from the **Auxiliary Geometry Definitions** list, details are displayed under **Properties**. You can then take the following actions:

   a. To revise the selected definition, click the **Edit...** button and change the setup using the **Auxiliary Geometry Definition** dialog box that opens.

   b. To display the selected definition in the graphics window, click the **Display** button.

   c. To delete the selected definition, click the **Delete** button.

Chapter 12: Modeling Flows Using Sliding and Dynamic Meshes

This chapter describes the setup and use of the sliding and dynamic mesh models in Ansys Fluent. To learn more about the theory of sliding meshes in Ansys Fluent, see Sliding Mesh Theory in the Theory Guide. For more information about the theory behind dynamic meshes in Ansys Fluent, see Dynamic Mesh Theory in the Theory Guide.

Understanding and using the sliding and deforming mesh models is presented in the following sections:

12.1. Introduction

12.2. Sliding Mesh Examples

12.3. The Sliding Mesh Technique

12.4. Sliding Mesh Interface Shapes

12.5. Using Sliding Meshes

12.6. Using Dynamic Meshes

12.1. Introduction

The sliding mesh model allows you to set up a problem in which separate zones move relative to each other. The motion can be translational or rotational. The relative motion of stationary and moving components (for example, in a rotating machine) will give rise to transient interactions. Often, the transient solution that is sought in a sliding mesh simulation is time-periodic. That is, the transient solution repeats with a period related to the speeds of the moving domains.

The dynamic mesh model allows you to move the boundaries of a cell zone relative to other boundaries of the zone, and to adjust the mesh accordingly. The boundaries can move rigidly with respect to each other (that is, linear or rotational motion), and/or deform.

When deciding whether to use a sliding mesh versus a dynamic mesh, consider the following:

- Many problems could be solved by either approach.
- If the problem does not involve mesh deformation, the sliding mesh model is recommended, as it is simpler and more efficient.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The dynamic mesh method must be used if the mesh is deforming, or if the mesh motion is a function of the solution (for example, the six degrees of freedom solver).

Important:

Sliding mesh and dynamic mesh are incompatible if they are combined within the same cell zone or adjacent cell zones. If you want to combine these two models within the same case file, they must be separated by a non-moving cell zone.

Note:

By default, transient simulations that involve a rotating fluid zone utilize a better flow field predictor that can speed up the calculation in some flow simulations. You can deactivate the flow field predictor by using the command `solve/set/transient-controls/rotating-mesh-flow-predictor?` and answering `no`.

For examples of typical sliding mesh and dynamic mesh problems, see Introduction in the Theory Guide.

12.2. Sliding Mesh Examples

When a time-accurate solution (rather than a time-averaged solution) for rotor-stator interaction is desired, you must use the sliding mesh model to compute the unsteady flow field. The sliding mesh model is the most accurate method for simulating flows in multiple moving reference frames, but also the most computationally demanding.

Most often, the unsteady solution that is sought in a sliding mesh simulation is time-periodic. That is, the unsteady solution repeats with a period related to the speeds of the moving domains. However, you can model other types of transients, including translating sliding mesh zones (for example, two cars or trains passing in a tunnel, as shown in Figure 12.1: Two Passing Trains in a Tunnel (p. 1767)). Note that the sliding mesh can be modeled using periodic boundaries (Figure 12.2: Rotor-Stator Interaction (Stationary Guide Vanes with Rotating Blades) (p. 1767)) or a circular/cylindrical interface (Figure 12.3: Blower (p. 1768)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.1: Two Passing Trains in a Tunnel

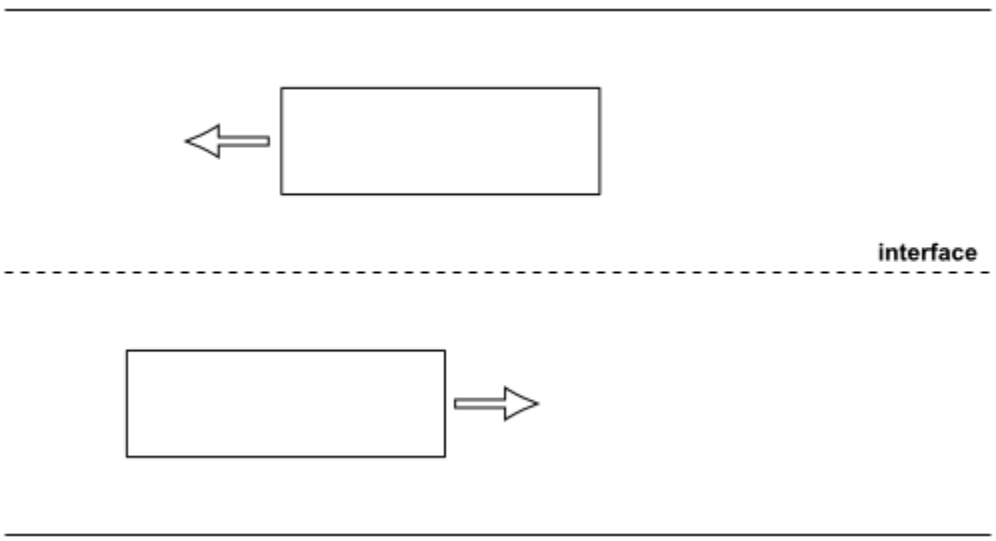

Figure 12.2: Rotor-Stator Interaction (Stationary Guide Vanes with Rotating Blades)

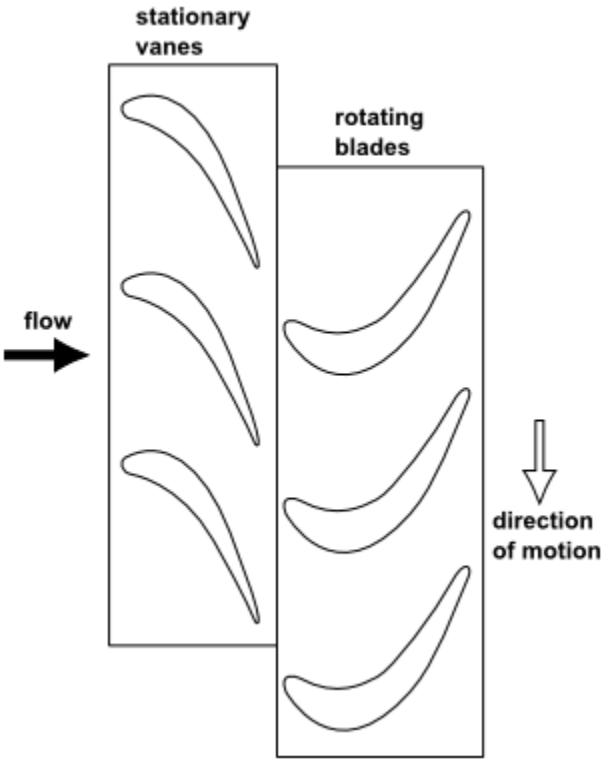

Figure 12.3: Blower

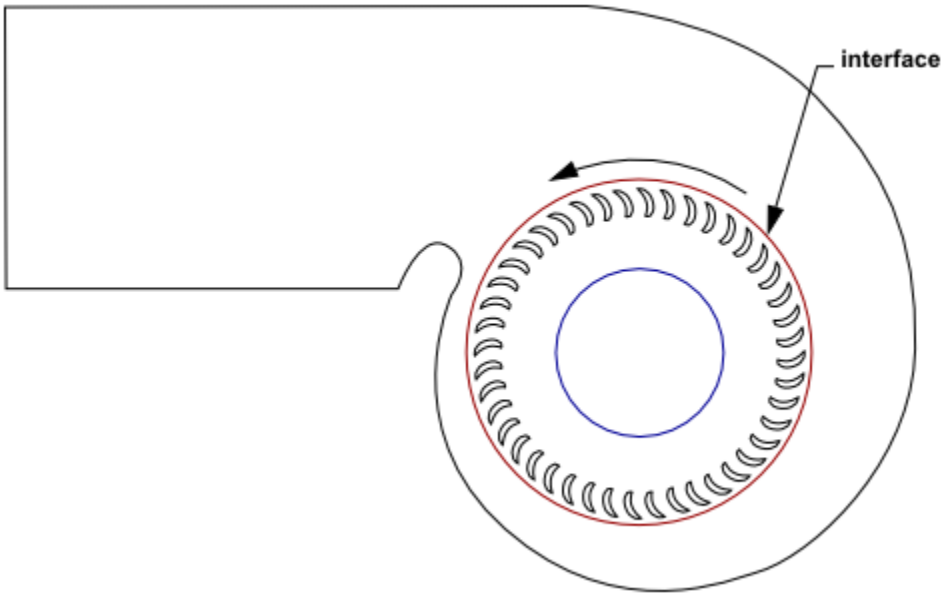

Note that for flow situations where there is no interaction between stationary and moving parts (for example, when there is only a rotor), it is not necessary to use a sliding mesh, and the moving reference frame model is recommended. (See Flow in a Moving Reference Frame for details.) If you are interested in a steady approximation of the interaction, you may use the multiple reference frame model or the mixing plane model, as described in The Multiple Reference Frame Model and The Mixing Plane Model in the Theory Guide.

12.3. The Sliding Mesh Technique

In the sliding mesh technique, two or more cell zones are used. (If you generate the mesh in each zone independently, you must merge the mesh files prior to starting the calculation, as described in Reading Multiple Mesh/Case/Data Files (p. 1135) in the User's Guide.) Each cell zone is bounded by at least one "interface zone" where it meets the opposing cell zone. The interface zones of adjacent cell zones are associated with one another to form a "mesh interface." The two cell zones will move relative to each other along the mesh interface.

During the calculation, the cell zones slide (that is, rotate or translate) relative to one another along the mesh interface in discrete steps. Figure 12.4: Initial Position of the Meshes (p. 1769) and Figure 12.5: Rotor Mesh Slides with Respect to the Stator (p. 1769) show the initial position of two meshes and their positions after some translation has occurred. Note that all non-conformal interfaces will be automatically updated (if necessary) by Ansys Fluent when the mesh is updated.

As the rotation or translation takes place, node alignment along the mesh interface is not required. Since the flow is inherently unsteady, a time-dependent solution procedure is required.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.4: Initial Position of the Meshes

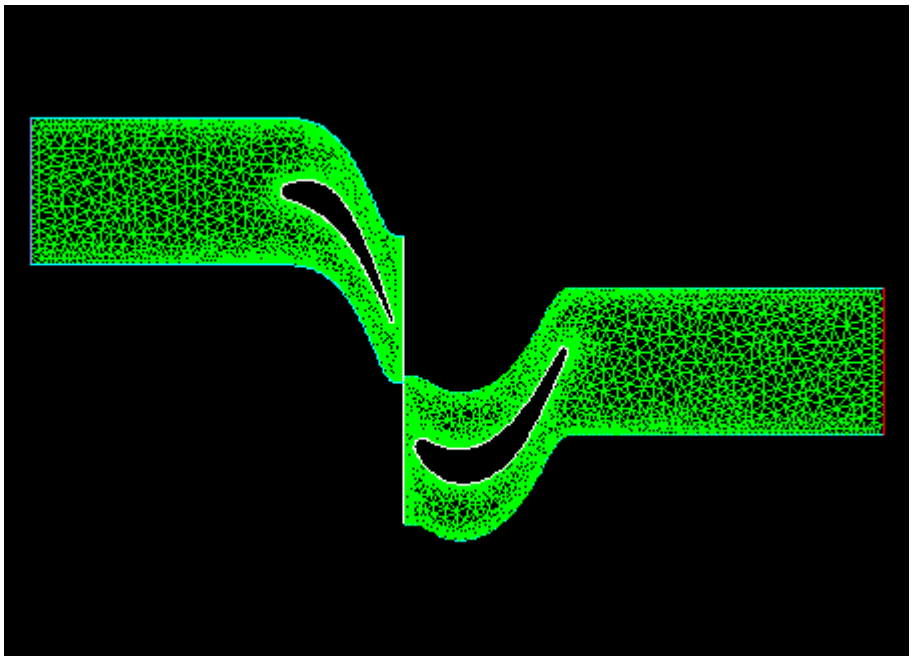

Figure 12.5: Rotor Mesh Slides with Respect to the Stator

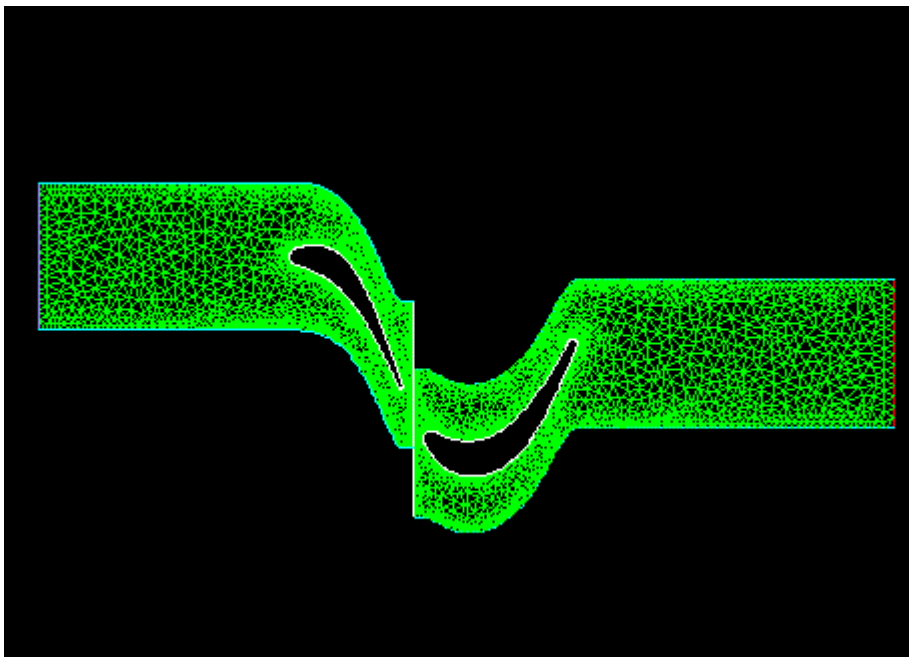

12.4. Sliding Mesh Interface Shapes

The mesh interface and the associated interface zones can be any shape, provided that the two interface boundaries are based on the same geometry. Figure 12.6: 2D Linear Mesh Interface (p. 1770) shows an example with a linear mesh interface and Figure 12.7: 2D Circular-Arc Mesh Interface (p. 1770) shows a circular-arc mesh interface. (In both figures, the mesh interface is designated by a dashed line.)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.6: 2D Linear Mesh Interface

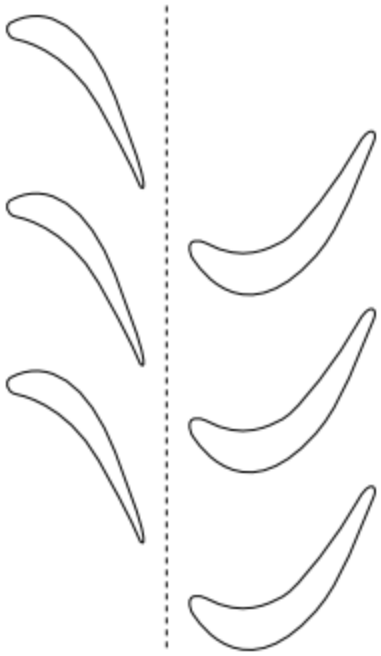

Figure 12.7: 2D Circular-Arc Mesh Interface

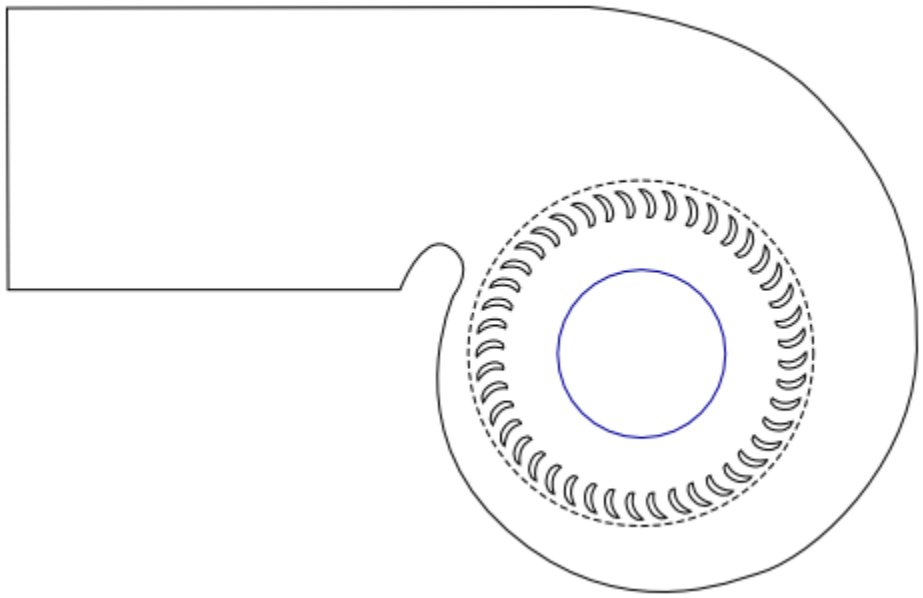
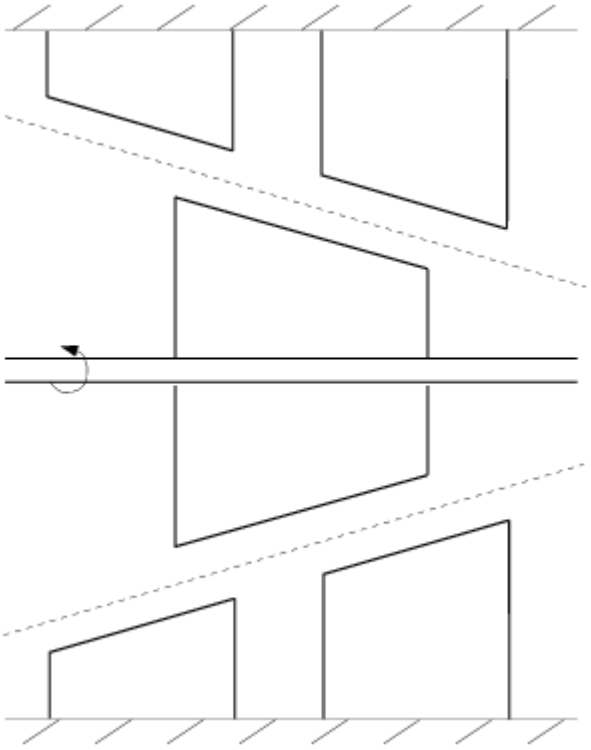


If Figure 12.6: 2D Linear Mesh Interface (p. 1770) was extruded to 3D, the resulting sliding interface would be a planar rectangle; if Figure 12.7: 2D Circular-Arc Mesh Interface (p. 1770) was extruded to 3D, the resulting interface would be a cylinder. Figure 12.8: 3D Conical Mesh Interface (p. 1771) shows an example that would use a conical mesh interface. (The slanted, dashed lines represent the intersection of the conical interface with a 2D plane.)

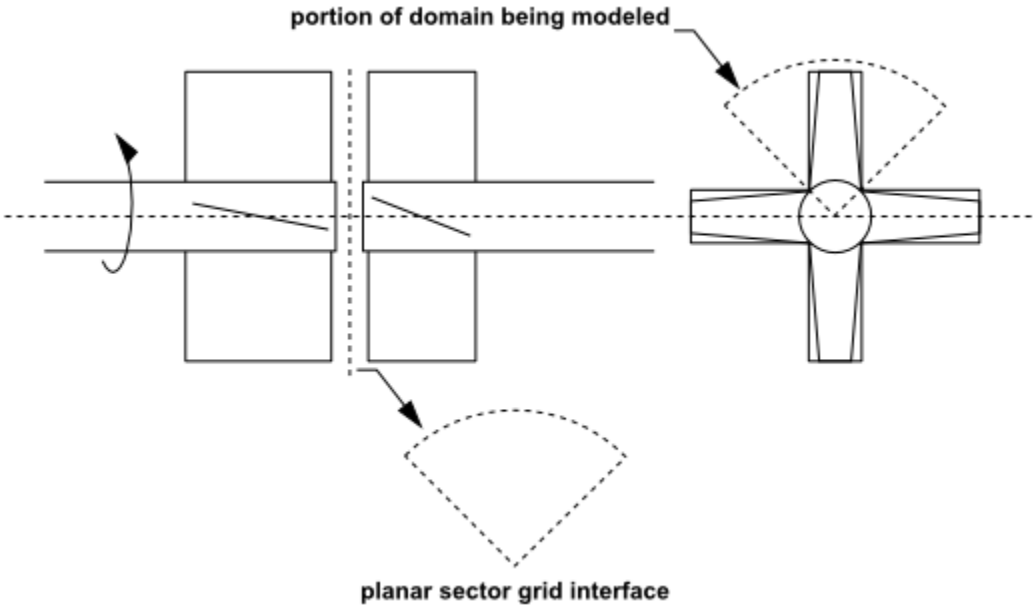
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.8: 3D Conical Mesh Interface



For an axial rotor/stator configuration, in which the rotating and stationary parts are aligned axially instead of being concentric (see Figure 12.9: 3D Planar-Sector Mesh Interface (p. 1771)), the interface will be a planar sector. This planar sector is a cross-section of the domain perpendicular to the axis of rotation at a position along the axis between the rotor and the stator.

Figure 12.9: 3D Planar-Sector Mesh Interface



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12.5. Using Sliding Meshes

This section describes how to use sliding meshes, including restrictions and constraints, problem setup, solution strategies, and postprocessing.

12.5.1. Requirements, Constraints, and Considerations
12.5.2. Setting Up the Sliding Mesh Problem
12.5.3. Solution Strategies for Sliding Meshes
12.5.4. Postprocessing for Sliding Meshes

12.5.1. Requirements, Constraints, and Considerations

Before beginning the problem setup in Ansys Fluent, be sure that the mesh you have created meets the following requirements:

- The mesh must have a different cell zone for each portion of the domain that is sliding at a different speed.
- The mesh interface must be situated such that there is no motion normal to it.
- The mesh interface can be any shape (including a non-planar surface, in 3D), provided that the two interface boundaries are based on the same geometry. If there are sharp features in the mesh (for example, 90-degree angles), it is especially important that both sides of the interface closely follow that feature.
- If you create a single mesh with multiple cell zones, you must be sure that each cell zone has a distinct face zone on the sliding boundary. The face zones for two adjacent cell zones will have the same position and shape, but one will correspond to one cell zone and one to the other. (Note that it is also possible to create a separate mesh file for each of the cell zones, and then merge them as described in Reading Multiple Mesh/Case/Data Files (p. 1135).)
- If you are modeling a rotor/stator geometry using periodicity, the periodic angle of the mesh around the rotor blade(s) must be the same as that of the mesh around the stationary vane(s).
- All periodic zones must be correctly oriented (either rotational or translational) before you create the mesh interface.
- Note the following limitations if you want to use the periodic repeats option as part of the mesh interface:
  - The periodic repeats option is not supported if the interface zone is adjacent to a solid zone.
  - The edges of the second interface zone must be offset from the corresponding edges of the first interface zone by a uniform amount (either a uniform translational displacement or a uniform rotation angle).
  - Some portion of the two interface zones must overlap (that is, be spatially coincident).
  - The non-overlapping portions of the interface zones must have identical shape and dimensions at all times during the mesh motion.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

  – One pair of conformal periodic zones must be adjacent to each of the interface zones. For example, when you calculate just one channel and blade of a fan, turbine, and so on, you must have conformal periodics on either side of the interface threads. This will not work with non-conformal periodics.

    Note that for 3D cases, you cannot have more than one pair of conformal periodic zones adjacent to each of the interface zones.

- You must not have a single sliding mesh interface where part of the interface is made up of a coupled two-sided wall, while another part is not coupled (that is, the normal interface treatment). In such cases, you must break the interface up into two interfaces: one that is a coupled interface, and the other that is a standard fluid-fluid interface. See Using a Non-Conformal Mesh in Ansys Fluent (p. 1164) for information about creating coupled interfaces.

- When using the sliding mesh technique, mass fluxes are interpolated from the sliding interface faces to the sliding boundary faces, which can affect the local mass balance at the sliding boundary. This can result in pressure field oscillations at the sliding boundary. These oscillations may be reduced by ensuring the surface mesh node distributions are similar on either side of the sliding boundaries. You can use the matching option (Matching Option (p. 1156)), where applicable, to reduce solution oscillations at the sliding boundaries.

- When using a sliding mesh to simulate flow through narrow gaps that open or close over time (such as in a valve or a rotary pump), you can use the gap model to block or decelerate the flow when the gaps are closed (as described in Controlling Flow in Narrow Gaps for Valves and Pumps (p. 1211)).

For details about these restrictions and general information about how the sliding mesh model works in Ansys Fluent, see The Sliding Mesh Technique (p. 1768).

12.5.2. Setting Up the Sliding Mesh Problem

The steps for setting up a sliding mesh problem are listed below. (Note that this procedure includes only those steps necessary for the sliding mesh model itself; you must set up other models, boundary conditions, and so on, as usual.)

1. Enable the appropriate option for modeling transient flow. (See Performing Time-Dependent Calculations (p. 3629) for details about the transient modeling capabilities in Ansys Fluent.)

   Setup → **General** **Analysis Type** → **Transient**

2. Set the cell zone conditions for the sliding motion:

   Setup → **Cell Zone Conditions**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In the Fluid Dialog Box (p. 4909) or Solid Dialog Box (p. 4921) of each moving fluid or solid zone, enable the **Mesh Motion** option and set the translational and/or rotational velocity under the **Mesh Motion** tab.

Important:

Note that simultaneous translation and rotation can be modeled only if the rotation axis and the translation direction are the same (that is, the origin is fixed).

Note that the speed can be specified as a constant value or a transient profile. The transient profile may be in a file format, as described in Transient Cell Zone and Boundary Conditions (p. 1499), or a UDF macro, described in `DEFINE_TRANSIENT_PROFILE` in the Fluent Customization Manual. Specifying the individual velocities as either a profile or a UDF allows you to specify a single component of the sliding motion individually. However, you can also specify the sliding motion using a user-defined function. This may prove to be quite convenient if you are modeling a more complicated motion, where the hooking of many different user-defined functions or profiles can be cumbersome.

Note:

If you decide to hook a UDF, then you will no longer have access to the rotation axis origin and direction, or the velocities.

3. Set the boundary conditions for the sliding motion:

   Setup → **Boundary Conditions**

   Change the zone **Type** of the interface zones of adjacent cell zones to **interface** in the Boundary Conditions Task Page (p. 4937).

   By default, the velocity of a wall is set to zero relative to the motion of the adjacent mesh. For walls bounding a moving mesh this results in a “no-slip” condition in the reference frame of the mesh. Therefore, you need not modify the wall velocity boundary conditions unless the wall is stationary in the absolute frame, and therefore moving in the relative frame. See Velocity Conditions for Moving Walls (p. 1440) for details about wall motion.

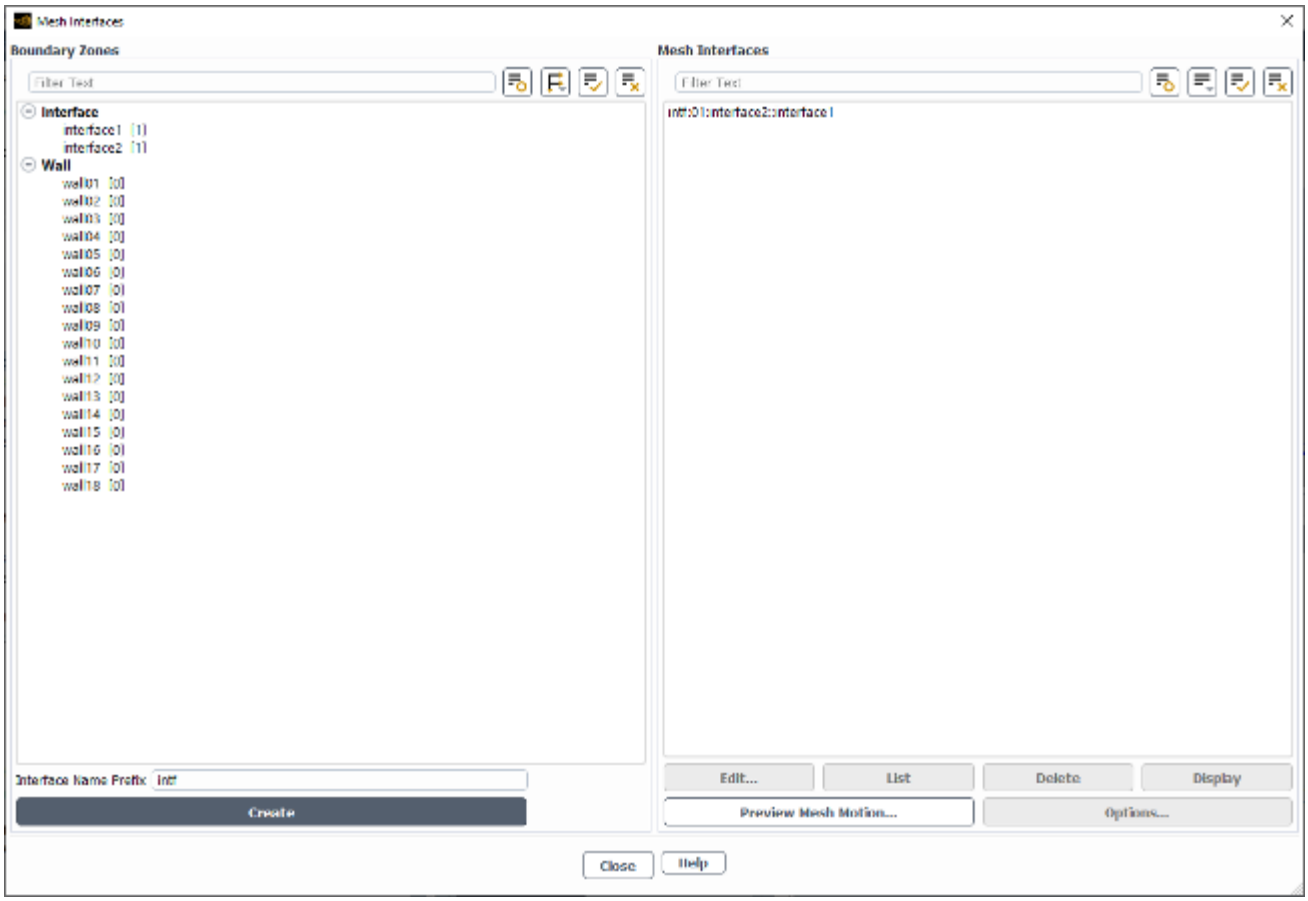
   See Cell Zone and Boundary Conditions (p. 1277) for details about inputting cell zone and boundary conditions.

4. Define the mesh interfaces using the Mesh Interfaces Dialog Box (p. 5468) (Figure 12.10: The Mesh Interfaces Dialog Box (p. 1775)).

   Setup → **Mesh Interfaces** → **New...**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.10: The Mesh Interfaces Dialog Box



To learn how to use the **Mesh Interfaces** dialog box, see Using a Non-Conformal Mesh in Ansys Fluent (p. 1164). Note that the **Interface Options** that are relevant for sliding meshes are **Periodic Repeats**, **Coupled Wall**, and **Matching** (for more information on these options, see Non-Conformal Mesh Calculations (p. 1149)).

5. Preview the mesh motion using the **Zone Motion** dialog box, which can be opened from the **Run Calculation** task page.

   Solution → Run Calculation → Preview Mesh Motion...

   For details about using the **Zone Motion** dialog box, see Previewing the Dynamic Mesh (p. 1890).

Important:

When you have completed the problem setup, you should save an initial case file so that you can easily return to the original mesh position (that is, the positions before any sliding

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

occurs). The mesh position is stored in the case file, so case files that you save at different times during the transient calculation will contain meshes at different positions.

Important:

If you want to go from an MRF model setup to a sliding mesh setup, use the following text command:

`mesh` → `modify-zones` → `mrf-to-sliding-mesh`

To successfully switch from an MRF to a sliding mesh, you must provide the ID of the fluid zone. Ansys Fluent identifies all the interior boundary zones of this fluid zone, as well as any adjacent fluid zones. Ansys Fluent changes these interior boundary zones into coupled walls, and then decouples these walls and changes them to interface zones. Ansys Fluent then changes the cell zone condition of the fluid zone to **Moving Mesh** in the Fluid Dialog Box (p. 4909). You do not need to do this if you have already created a mesh interface. The sliding mesh solution tends to be more robust than the MRF solution.

Note that *all* of the interfaces between the cells zones must be interior boundaries. This means that this text command cannot be used for a thermal simulation with solid zones adjacent to the MRF zone (for example, an MRF zone in contact with a solid volute).

12.5.3. Solution Strategies for Sliding Meshes

You will begin the sliding mesh calculation by initializing the solution (as described in Initializing the Entire Flow Field Using Standard Initialization (p. 3614)) and then specifying the time step size and number of time steps in the Run Calculation Task Page (p. 5153), as for any other transient calculation. (See Performing Time-Dependent Calculations (p. 3629) for details about time-dependent solutions.) Note that the time step size in the initial case file is saved without clicking **Calculate**. Ansys Fluent will iterate on the current time step solution until satisfactory residual reduction is achieved, or the maximum number of iterations per time step is reached. When it advances to the next time step, the cell and wall zones will automatically be moved according to the specified translational or rotational velocities (as discussed in the previous section). The new interface-zone intersections will be computed automatically, and resultant interior/periodic/external boundary zones will be updated.

Note that you can run the MRF case using mesh interfaces with an appreciable loss of accuracy, doing so makes it easier to later on convert to a sliding mesh.

Note:

The sliding mesh can be initialized with an MRF solution (rather using Standard or Hybrid initializations).

It is recommended that you preview the sliding mesh motion (as described in Previewing the Dynamic Mesh (p. 1890)) before beginning your calculation. This can catch problems with the motion specification(s) before you begin the CFD calculation. Remember to save the case and initial data files before doing a mesh preview since the mesh position is altered once you do the preview. You can reread the initial condition case/data files to get back to the original mesh position.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12.5.3.1. Saving Case and Data Files

Ansys Fluent's automatic saving of case and data files (see Automatic Saving of Case and Data Files (p. 934)) can be used with the sliding mesh model. This provides a convenient way for you to save results at successive time steps for later postprocessing.

Important:

You must save a case file each time you save a data file because the mesh position is stored in the case file. Since the mesh position changes with each time step, reading data for a given time step will require the case file at that time step so that the mesh will be in the proper position. You should also save your initial case file so that you can easily return to the mesh's original position to restart the solution if desired.

12.5.3.2. Time-Periodic Solutions

For some problems (for example, rotor-stator interactions), you may be interested in a time-periodic solution. That is, the startup transient behavior may not be of interest to you. Once this startup phase has passed, the flow will start to exhibit time-periodic behavior. If T is the period of unsteadiness, then for some flow property ϕ at a given point in the flow field:

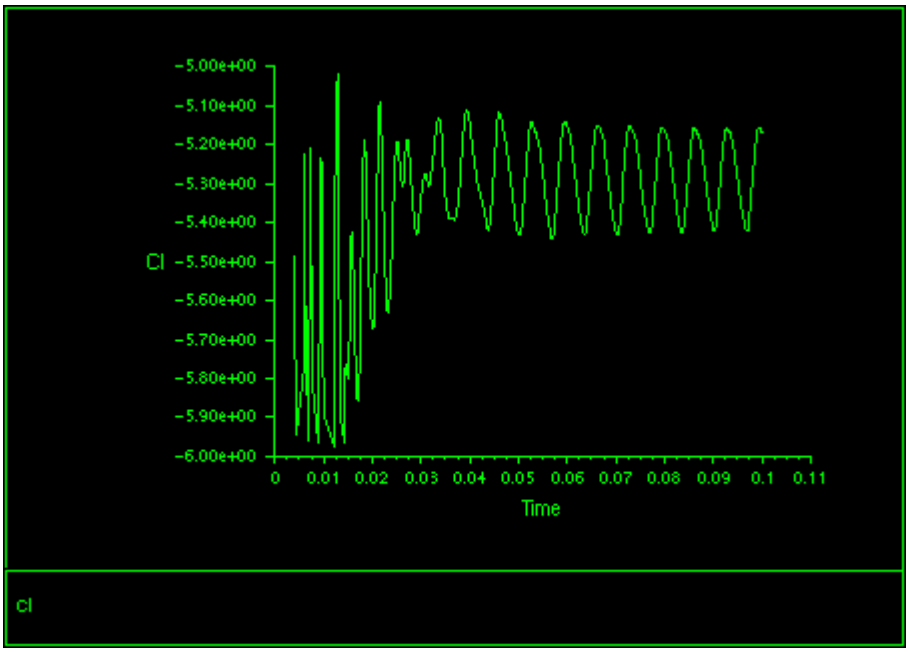
$$\phi(t)=\phi(t+NT)(N=1,2,3,\ldots) \tag{12.1}$$

For rotating problems, the period (in seconds) can be calculated by dividing the sector angle of the domain (in radians) by the rotor speed (in radians/sec): $T=\theta/\Omega$. For 2D rotor-stator problems, $T=P/v_b$, where P is the pitch and v_b is the blade speed. The number of time steps in a period can be determined by dividing the time period by the time step size. When the solution field does not change from one period to the next (for example, if the change is less than 5%), a time-periodic solution has been reached.

To determine how the solution changes from one period to the next, you must compare the solution at some point in the flow field over two periods. For example, if the time period is 10 seconds, you can compare the solution at a given point after 22 seconds with the solution after 32 seconds to see if a time-periodic solution has been reached. If not, you can continue the calculation for another period and compare the solutions after 32 and 42 seconds, and so on until you see little or no change from one period to the next. You can also track global quantities, such as lift and drag coefficients and mass flow, in the same manner. Figure 12.11: Lift Coefficient Plot for a Time-Periodic Solution (p. 1778) shows a lift coefficient plot for a time-periodic solution.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.11: Lift Coefficient Plot for a Time-Periodic Solution



The final time-periodic solution is independent of the size of the time steps taken during the initial stages of the solution procedure. You can therefore define a "large" time step size in the initial stages of the calculation, since you are not interested in a time-accurate solution for the startup phase of the flow. Starting out with a large time step size will allow the solution to become time-periodic more quickly. As the solution becomes time-periodic, however, you should reduce size of the time steps in order to achieve a time-accurate result.

Important:

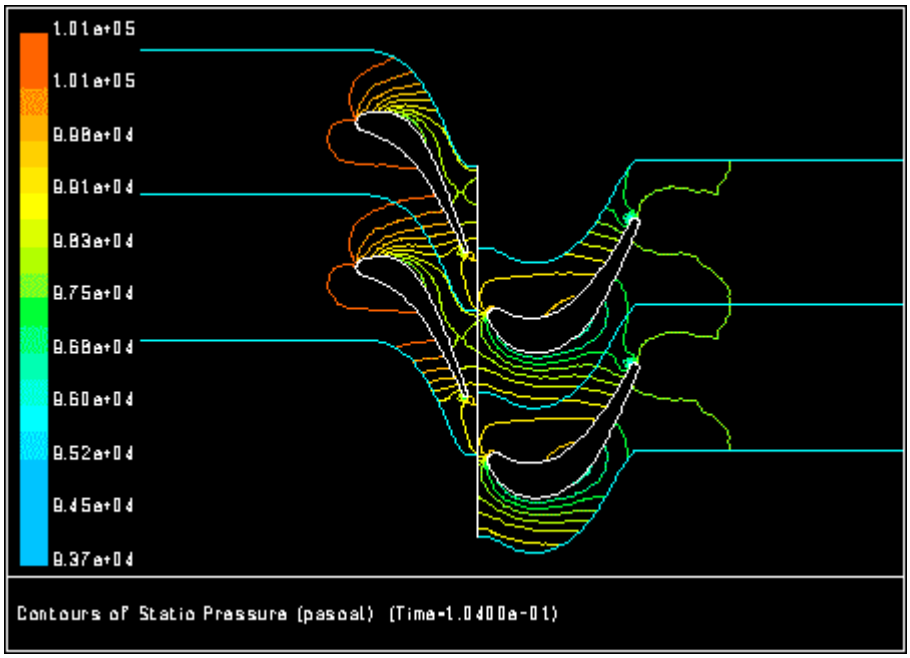
If you are solving with second-order time accuracy, the temporal accuracy of the solution will be affected if you change the time step size during the calculation. You may start out with a larger time step size, but you should not change the time step size by more than 20% during the solution process. You should not change the time step size at all during the last several periods to ensure that the solution has approached a time-periodic state.

12.5.4. Postprocessing for Sliding Meshes

Postprocessing for sliding mesh problems is the same as for other transient problems. You will read in the case and data file for the time of interest and display and report results as usual. For spatially-periodic problems, you may want to use periodic repeats (set in the Views Dialog Box (p. 5218), as described in Controlling the Display State and Modifying the View (p. 3993)) to display the geometry. Figure 12.12: Contours of Static Pressure for the Rotor-Stator Example (p. 1779) shows the flow field for the rotor-stator example in Figure 12.4: Initial Position of the Meshes (p. 1769)) at one instant in time, using 1 periodic repeat.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.12: Contours of Static Pressure for the Rotor-Stator Example



When displaying velocity vectors, note that absolute velocities (that is, velocities in the inertial, or laboratory, reference frame) are displayed by default. You may also choose to display relative velocities by selecting **Relative Velocity** in the **Vectors of** drop-down list in the Vectors Dialog Box (p. 5597). In this case, velocities relative to the translational/rotational velocity of the "reference zone" (specified in the Reference Values Task Page (p. 5100)) will be displayed. (The velocity of the reference zone is the velocity defined in the Fluid Dialog Box (p. 4909) for that zone.)

Note that you cannot create zone surfaces for the intersection boundaries (that is, the interior/periodic/external zones created from the intersection of the interface zones). You may instead create zone surfaces for the interface zones. Data displayed on these surfaces will be "one-sided". That is, nodes on the interface zones will "see" only the cells on one side of the mesh interface, and slight discontinuities may appear when you plot contour lines across the interface. Note also that, for non-planar interface shapes in 3D, you may see small gaps in your plots of filled contours. These discontinuities and gaps are only graphical in nature. The solution does not have these discontinuities or gaps. To eliminate these discontinuities for postprocessing purposes only, you can use the `define/mesh-interfaces/enforce-continuity-after-bc?` text command, which will ensure that continuity will take precedence over the boundary condition.

You can also generate a plot of circumferential averages in Ansys Fluent. This allows you to find the average value of a quantity at several different radial or axial positions in your model. Ansys Fluent computes the average of the quantity over a specified circumferential area, and then plots the average against the radial or axial coordinate. For more information on generating XY plots of circumferential averages, see XY Plots of Circumferential Averages (p. 4035).

Sliding mesh results can be analyzed by employing the time averaging (or RMSE averaging) option (**Data Sampling for Time Statistics**) in the **Run Calculation** task page. This will compute time averages for velocity, pressure, temperature, and turbulence. You must plan ahead since you have to engage the time averaging after the solution has become time-periodic and run for at least one period of the oscillating flow field.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12.6. Using Dynamic Meshes

The steps for setting up a dynamic mesh problem are listed below. (Note that this procedure includes only those steps necessary for the dynamic mesh model itself; you must set up other models, cell zone conditions, boundary conditions, and so on, as usual.)

1. Enable the appropriate option for modeling transient or steady flow in the General Task Page (p. 4632).

   Setup → **General**

   If your problem involves a steady flow, see Steady-State Dynamic Mesh Applications (p. 1892) for important considerations.

2. Set cell zone conditions and boundary conditions as required in the Cell Zone Conditions Task Page (p. 4906) and Boundary Conditions Task Page (p. 4937).

   Setup → **Cell Zone Conditions**

   Setup → **Boundary Conditions**

   See Cell Zone and Boundary Conditions (p. 1277) for information about inputting conditions. The correct wall velocity is set up automatically when a dynamic zone is created for a wall zone and the motion attributes are specified, so you will not specify wall motion in the **Wall** dialog box. If you create a moving dynamic cell zone, then all wall boundaries adjacent to that cell zone will, by default, impose the correct (moving) boundary conditions, and it is not necessary to declare these wall zones as dynamic zones. Note that if a wall boundary mesh is moving because it belongs to an adjacent moving dynamic cell zone, but the physical boundary conditions are such that the wall is actually not moving, then you will have to declare this boundary as a dynamic zone and specify that the mesh motion is not included in the boundary conditions (see Specifying the Motion of Dynamic Zones (p. 1872)).

3. Enable the dynamic mesh model, and specify related parameters in the Dynamic Mesh Task Page (p. 5057).

   Setup → **Dynamic Mesh** → **Dynamic Mesh**

   See Setting Dynamic Mesh Modeling Parameters (p. 1782) for details.

4. Create the dynamic zones for your model, using the Dynamic Mesh Zones Dialog Box (p. 5086).

   Setup → **Dynamic Mesh** → **Create/Edit...**

   See Specifying the Motion of Dynamic Zones (p. 1872) for details.

5. You can display the motion of the moving zones with prescribed motion to verify the simulation setup.

   Setup → **Dynamic Mesh** → **Display Zone Motion...**

   See Previewing the Dynamic Mesh (p. 1890) for details.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. If it is a transient simulation, define the events that will occur during the calculation.

   Setup → Dynamic Mesh → Events...

   See Defining Dynamic Mesh Events (p. 1862) for details.

7. Save the case and data.

   File → Write → Case & Data...

8. Preview your dynamic mesh setup (when the motion is a prescribed motion). See Steady-State Dynamic Mesh Applications (p. 1892) for previewing your steady-state dynamic mesh motion and refer to Previewing the Dynamic Mesh (p. 1890) for details.

   Setup → Dynamic Mesh → Preview Mesh Motion...

9. Specify the pressure-velocity coupling scheme. For transient flow calculations, the PISO algorithm is recommended, as it is the most efficient for such cases (see PISO (p. 3572) for details).

10. Use the automatic saving feature to specify the file name and frequency with which case and data files should be saved during the solution process.

    Solution → Calculation Activities → Autosave (Every) → Edit...

    See Automatic Saving of Case and Data Files (p. 934) for details about the use of this feature. This provides a convenient way for you to save results at successive time steps for later postprocessing.

    Important:

    You must save a case file each time you save a data file because the mesh position is stored in the case file. Since the mesh position changes with each time step, reading data for a given time step will require the case file at that time step so that the mesh will be in the proper position. You should also save your initial case file so that you can easily return to the mesh's original position to restart the solution if desired.

11. (optional) If you want to create a graphical animation of the mesh over time during the solution procedure, you can use the Calculation Activities Task Page (p. 5134) to set up the graphical displays that you want to use in the animation. See Animating the Solution (p. 3700) for details.

12.6.8. Defining Dynamic Mesh Events
12.6.9. Specifying the Motion of Dynamic Zones
12.6.10. Previewing the Dynamic Mesh
12.6.11. Steady-State Dynamic Mesh Applications

12.6.1. Setting Dynamic Mesh Modeling Parameters

To enable the dynamic mesh model, enable **Dynamic Mesh** in the Dynamic Mesh Task Page (p. 5057) (Figure 12.13: The Dynamic Mesh Task Page (p. 1783)).

Setup → **Dynamic Mesh** → **Dynamic Mesh**

Then, enable the appropriate options in the **Options** group box. If you are modeling in-cylinder motion, enable the **In-Cylinder** option. If you are going to use the six degrees of freedom solver, then enable the **Six DOF** option. If you want to specify periodic displacement based on a mode shape for blade flutter analysis, select **Periodic Displacement**. If you want to have the dynamic mesh updated during a time step (as opposed to just at the beginning of a time step), then enable the **Implicit Update** option. More information about these options and the related settings can be found in In-Cylinder Settings (p. 1836), Six DOF Solver Settings (p. 1851), Defining the Periodic Displacement of the Blades (p. 1946), and Implicit Update Settings (p. 1856), respectively.

Next, you must select the appropriate mesh update methods in the **Mesh Methods** group box, and set the associated parameters, if relevant. See Dynamic Mesh Update Methods (p. 1784) for details.

12.6.2. Dynamic Mesh Update Methods

Three groups of mesh motion methods are available in Ansys Fluent to update the volume mesh in the deforming regions subject to the motion defined at the boundaries:

- Smoothing Methods (p. 1784)
- Dynamic Layering (p. 1805)
- Remeshing (p. 1809)

Note that you can use Ansys Fluent's dynamic mesh models in conjunction with adaption, with the exception of dynamic layering (in almost all cases) and any remeshing method. For more information on the available adaption methods, see Hanging Node Adaption and Polyhedral Unstructured Mesh Adaption in the Theory Guide.

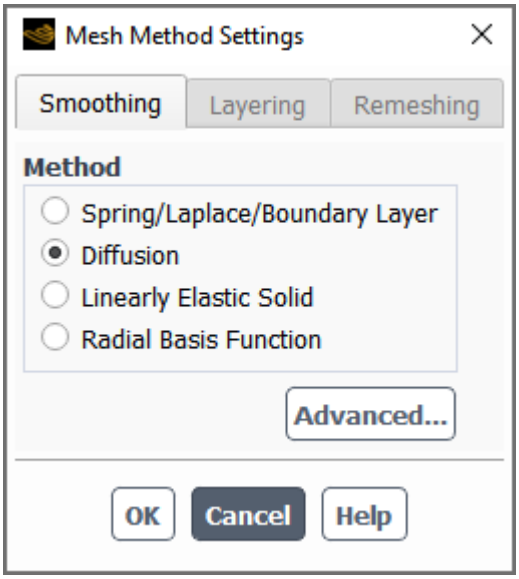
Details on how to set up the various dynamic mesh update methods are provided in the sections that follow.

12.6.2.1. Smoothing Methods

When smoothing is used to adjust the mesh of a zone with a moving and/or deforming boundary, the interior nodes of the mesh move, but the number of nodes and their connectivity does not change. In this way, the interior nodes "absorb" the movement of the boundary. To enable smoothing, perform the following steps:

1. Enable the **Smoothing** option in the **Mesh Methods** group box of the Dynamic Mesh Task Page (p. 5057).
2. Click the **Settings...** button to open the **Mesh Method Settings** dialog box.

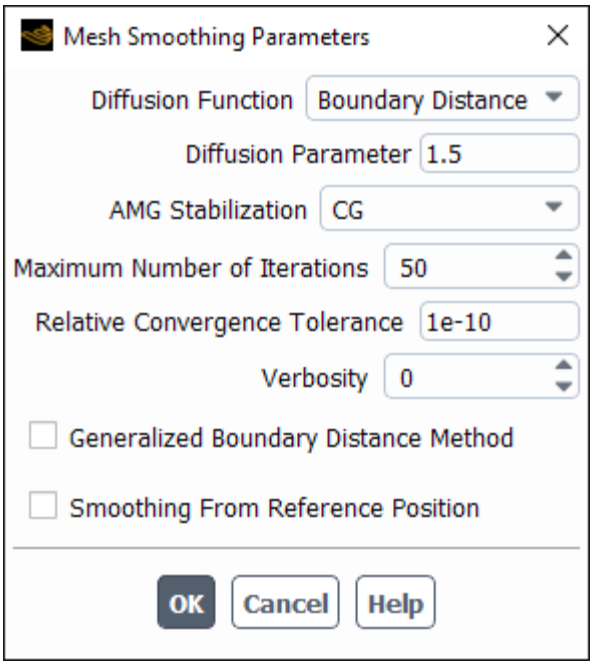
Figure 12.14: The Smoothing Tab of the Mesh Method Settings Dialog Box



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. If you want diffusion-based smoothing, select **Diffusion** from the **Method** list. Then click the **Advanced...** button and define the settings in the **Mesh Smoothing Parameters** dialog box. For details, see Diffusion-Based Smoothing (p. 1786).

Figure 12.15: The Mesh Smoothing Parameters Dialog Box



4. If you want spring-based smoothing, select **Spring/Laplace/Boundary Layer** from the **Method** list. Then click the **Advanced...** button and define the settings in the **Mesh Smoothing Parameters** dialog box. For details, see Spring-Based Smoothing (p. 1792).

5. If you want smoothing using the linearly elastic solid method, select **Linearly Elastic Solid** from the **Method** list. Then click the **Advanced...** button and define the settings in the **Mesh Smoothing Parameters** dialog box. For details, see Linearly Elastic Solid Based Smoothing Method (p. 1796).

6. If you want smoothing that is based on a radial basis function interpolation, select **Radial Basis Function** from the **Method** list. Then click the **Advanced...** button and define the settings in the **Mesh Smoothing Parameters** dialog box. For details, see Radial Basis Function Smoothing (p. 1798).

7. If you selected **Diffusion**, **Linearly Elastic Solid**, or **Radial Basis Function** smoothing and the simulation involves periodic or quasi-periodic motion, you can specify that the smoothing uses a reference position. This option may improve the mesh quality consistency from cycle to cycle—see Smoothing from a Reference Position (p. 1800) for details.

8. If you plan to apply the 2.5D remeshing method (as described in 2.5D Surface Remeshing Method (p. 1825)), perform the following steps to set up Laplacian smoothing (as described in Laplacian Smoothing Method (p. 1801)).

   a. Select **Spring/Laplace/Boundary Layer** from the **Method** list

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

b. Click the **Advanced...** button and define only the **Laplace Node Relaxation** and the **Maximum Number of Iterations** in the **Mesh Smoothing Parameters** group box (the other settings are not relevant).

9. If you plan to apply the boundary layer smoothing method (as described in Boundary Layer Smoothing Method (p. 1802)), select **Spring/Laplace/Boundary Layer** from the **Method** list.

12.6.2.1.1. Diffusion-Based Smoothing

For diffusion-based smoothing, the mesh motion is governed by the diffusion equation

$$\nabla \cdot \left(\gamma \nabla \vec{u} \right) = 0 \tag{12.2}$$

where $\vec{u}$ is the mesh displacement velocity. The boundary conditions for Equation 12.2 (p. 1786) are obtained from the user-prescribed or computed (six DOF) boundary motion. On deforming boundaries, the boundary conditions are such that the mesh motion is tangent to the boundary (that is, the normal velocity component vanishes). The Laplace equation Equation 12.2 (p. 1786) then describes how the prescribed boundary motion diffuses into the interior of the deforming mesh.

The diffusion coefficient γ in Equation 12.2 (p. 1786) can be used to control how the boundary motion affects the interior mesh motion. A constant coefficient means that the boundary motion diffuses uniformly throughout the mesh. With a nonuniform diffusion coefficient, mesh nodes in regions with high diffusivity tend to move together (that is, with less relative motion).

In Fluent, two different formulations for the diffusion coefficient γ are available for selection from the **Diffusion Function** drop-down list in the Mesh Smoothing Parameters Dialog Box (p. 5064). The first formulation allows you to have the diffusion coefficient be a function of the **Boundary Distance**, and is of the form

$$\gamma = \frac{1}{d^{\alpha}} \tag{12.3}$$

where d is a normalized boundary distance. The second formulation allows you to have the diffusion coefficient be a function of the **Cell Volume**, and is of the form

$$\gamma = \frac{1}{V^{\alpha}} \tag{12.4}$$

where V is the normalized cell volume. In both Equation 12.3 (p. 1786) and Equation 12.4 (p. 1786), $\alpha \geq 0$ is a user input parameter. See Diffusivity Based on Boundary Distance (p. 1790) and Diffusivity Based on Cell Volume (p. 1791) for information about defining the diffusion coefficient.

Ansys Fluent uses different numerical methods to solve the vector Equation 12.2 (p. 1786), depending on the element types present in the mesh. In the absence of polyhedral elements or elements with hanging nodes (that is, meshes that have undergone hanging node adaption and some hexcore or CutCell meshes) the equation is solved using a finite element discretization and the displacement velocity, $\vec{u}$, is obtained directly at each mesh node. If the mesh contains polyhedral elements or hanging nodes, the equation is discretized using Ansys Fluent's standard finite volume method and the cell-centered solution for the displacement velocity, $\vec{u}$, is interpolated onto the nodes using inverse-distance-weighted averaging. The node positions are then updated according to:

$$\vec{x}_{new} = \vec{x}_{old} + \vec{u} \Delta t \tag{12.5}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The finite element discretization is generally superior, as the solution is obtained directly at the nodes and no interpolation step is necessary. The finite volume method can be enforced for meshes of all element types by executing the TUI command:

```
/define/dynamic-mesh/controls/smoothing-parameters/diffusion-fvm? yes
```

With finite element discretization, you can specify the solution method used by the linear solver for the diffusion-based smoothing calculations. By default, the **CG** (conjugate gradient) method is selected from the **AMG Stabilization** drop-down list. This method should be faster in this context than the other available methods, as it takes advantage of the symmetry of the matrix used in the linear systems of equations of finite-element-based mesh smoothing. If divergence is detected with CG, then the generalized minimal residual (GMRES) method will be used for an iteration as a fallback, and you will be informed in the console that a finite-element-based mesh smoothing coupled equation is being stabilized to enhance linear solver robustness. In rare cases, the CG method may result in the generation of negative volume cells; you may be able to avoid this by increasing the **Maximum Number of Iterations** from the default of 50 to a value in the range of 200–500.

If the CG method continues to generate negative volume cells with a higher number of iterations or if you repeatedly see console messages that say the GMRES fallback is being used, it is recommended that you select **GMRES** from the **AMG Stabilization** drop-down list. Note that the GMRES method is more robust than the CG method, especially for high-aspect-ratio meshes; but it is also more demanding in terms of memory usage and solver time.

Note that this drop-down list also allows you to select the **BCGSTAB** (bi-conjugate gradient stabilized) method; like the CG method, BCGSTAB falls back to the GMRES method for an iteration when divergence is detected.

Computationally, solving a PDE for mesh smoothing is generally more costly than spring-based smoothing. But it tends to produce better quality meshes than spring-based smoothing and often allows larger boundary deformations before breaking down. Figure 12.16: The Initial Mesh (p. 1788) and Figure 12.17: Valid Mesh After 45 Degree Rotation Using Diffusion-Based Smoothing (p. 1788) show a mesh before and after rotating the boundary by 45 degrees, using diffusion-based smoothing. With spring-based smoothing, the same mesh shows degenerated cells after a rotation of 40 degrees (Figure 12.18: Degenerated Mesh After 40 Degree Rotation Using Spring-Based Smoothing (p. 1789)). (Note that radial basis function smoothing handles rotation better than both diffusion- and spring-based smoothing.)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.16: The Initial Mesh

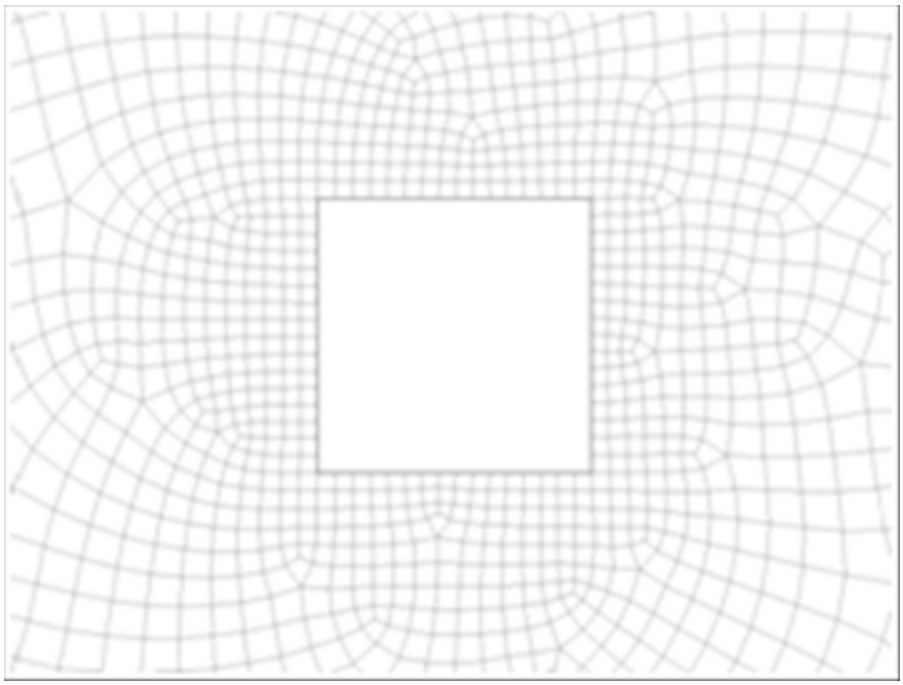


Figure 12.17: Valid Mesh After 45 Degree Rotation Using Diffusion-Based Smoothing

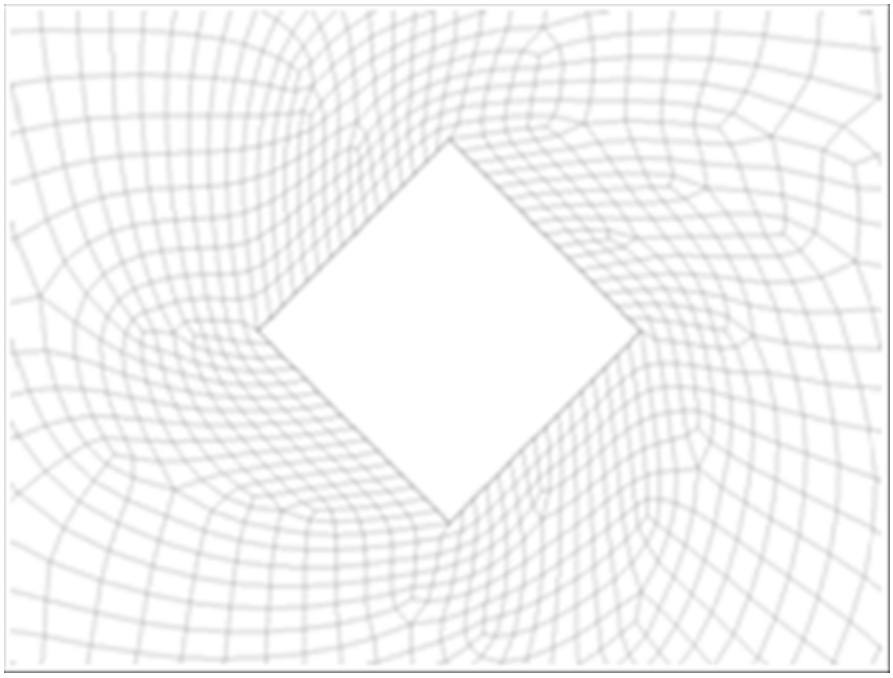
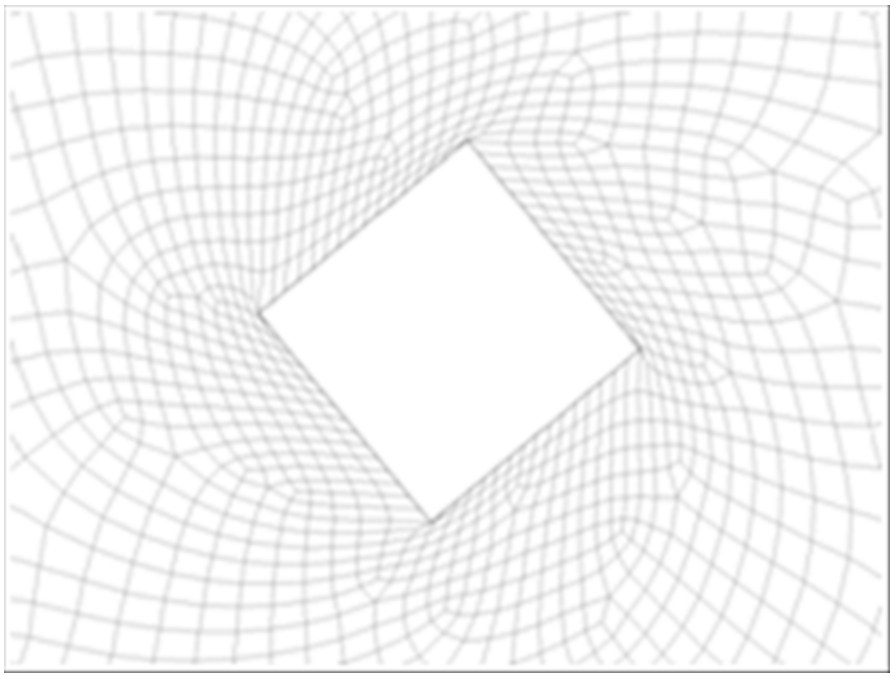


Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.18: Degenerated Mesh After 40 Degree Rotation Using Spring-Based Smoothing



It should be noted that with diffusion-based smoothing the interior mesh motion is governed by the solution to Equation 12.2 (p. 1786) and the prescribed boundary motion, and not by mesh irregularities. Poor quality elements or mesh defects are not smoothed out by this method, but rather move together with the pre-computed (at the begin of each mesh update) displacement velocity $\vec{u}$.

It is also worth noting that the nature of the diffusion equation is such that the resulting solution (that is, the displacement velocity $\vec{u}$) depends on the dimensionality of the problem and the type of boundary motion prescribed. To illustrate the impact of the type of boundary motion, consider the goal of boundary-distance-based diffusion (Equation 12.3 (p. 1786)): to control which parts of the mesh absorb the boundary motion, so that you can preserve the mesh in the vicinity of the moving boundary (at the expense of the interior of the mesh). For more translational (piston-type) boundary motions, you can preserve a reasonably "thick" region of the mesh adjacent to the boundary (that is, multiple layers of cells); for rotational boundary motions, the rate of decay for the solution as you move away from the boundary is such that it can be difficult to preserve even a "thin" region. For this reason, mesh smoothing can handle translational boundary motions generally much better than rotational motions.

Although it should in most cases not be necessary, the accuracy of the solution to the diffusion equation governing the mesh motion can be controlled by defining the **Maximum Number of Iterations** and the **Relative Convergence Tolerance**.

You can enable printing of smoothing residuals in the console by entering 1 for the **Verbosity**.

For simulations with periodic or quasi-periodic motion, you can improve the mesh quality consistency by specifying that the diffusion-based smoothing uses a reference position, as described in Smoothing from a Reference Position (p. 1800).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

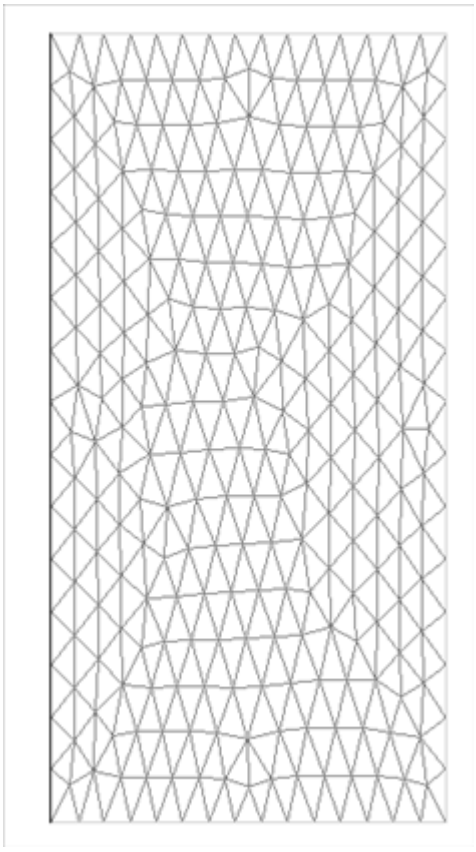
12.6.2.1.1.1. Diffusivity Based on Boundary Distance

Using boundary-distance-based diffusion (Equation 12.3 (p. 1786)) allows you to control how the boundary motion diffuses into the interior of the domain as a function of boundary distance. Decreasing the diffusivity away from the moving boundary causes those regions to absorb more of the mesh motion, and better preserves the mesh quality near the moving boundary. This is particularly helpful for a moving boundary that has pronounced geometrical features (such as sharp corners) along with a prescribed motion that is predominantly rotational.

You can manipulate the diffusion coefficient γ (in Equation 12.3 (p. 1786)) primarily by adjusting the **Diffusion Parameter** in the Mesh Smoothing Parameters Dialog Box (p. 5064) (α). A range of 0 to 2 has been shown to be of practical use. A value of 0 (the default value) specifies that $\gamma=1$ and yields a uniform diffusion of the boundary motion throughout the mesh. Higher values of α preserve larger regions of the mesh near the moving boundary, and cause the regions away from the moving boundary to absorb more of the motion.

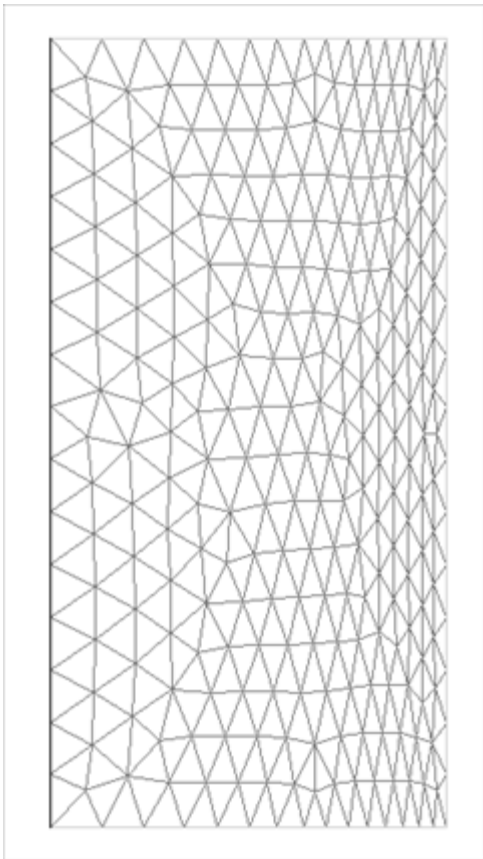
The following two figures illustrate the effect of the **Diffusion Parameter** α on the resulting mesh for a translational (piston-type) boundary motion, when the diffusivity is based on the boundary distance. In this example, an initially uniformly meshed square domain is deformed by moving the left boundary to the right.

Figure 12.19: Effect of Diffusion Parameter of 0 on Interior Node Motion



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.20: Effect of Diffusion Parameter of 1 on Interior Node Motion



For rotational boundary motions, a value of 1.5 for the **Diffusion Parameter** α is recommended as a good starting point.

Two different methods are available for the evaluation of the boundary distance d if boundary-distance-based diffusion is used. By default, Fluent uses the "standard" boundary distance in Equation 12.3 (p. 1786), which is the normalized distance to the nearest wall boundary; note that none of the other boundary types (for example, inlets, outlets, symmetry, and periodic boundaries) are considered. This method is the same as that which is used to evaluate the boundary distance for turbulence models. An example of this method is shown in Figure 12.20: Effect of Diffusion Parameter of 1 on Interior Node Motion (p. 1791), where only the left and right boundaries are walls. You have the option of enabling the **Generalized Boundary Distance Method** option instead, so that d is the normalized distance to the nearest boundary that is not declared as deforming, regardless of type. Both methods use the largest distance found in all deforming cell zones to normalize the value.

If the generalized boundary distance is used, an additional scalar equation for the boundary distance d will be solved as part of the solution of Equation 12.2 (p. 1786).

12.6.2.1.1.2. Diffusivity Based on Cell Volume

Using cell-volume-based diffusion (Equation 12.4 (p. 1786)) allows you to control how the boundary motion diffuses into the interior of the domain as a function of cell size. Decreasing the diffusivity in larger cells causes those cells to absorb more of mesh motion and therefore better preserves the cell quality of smaller cells.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can manipulate the diffusion coefficient γ (in Equation 12.3 (p. 1786)) by adjusting the **Diffusion Parameter** in the Mesh Smoothing Parameters Dialog Box (p. 5064) (α). A value of 0 (the default value) specifies that $\gamma=1$ and yields a uniform diffusion of the boundary motion throughout the mesh. Higher values of α result in larger cells absorbing more of the motion than smaller cells.

Note that the cell volume used in Equation 12.4 (p. 1786) is the local cell volume, normalized by the average cell volume of all deforming cell zones.

12.6.2.1.1.3. Applicability of the Diffusion-Based Smoothing Method

Diffusion-based mesh smoothing can be used to update any cell zone whose boundaries are moving or deforming. It is available for all element types, though it is not as robust for polyhedral elements as radial basis function smoothing.

Diffusion-based smoothing is computationally more expensive than spring-based smoothing, but likely results in better mesh quality (especially for non-tetrahedral / non-triangular cell zones, and for polyhedral cells in particular) and generally allows for larger boundary deformations before breaking down.

Similar to spring-based smoothing, diffusion-based mesh smoothing can handle translational boundary deformations much better than rotational motions. Rotational motions are best handled by radial basis function smoothing.

Diffusion-based smoothing is not compatible with the boundary layer smoothing method or the face region remeshing method. For more information about these methods, see Boundary Layer Smoothing Method (p. 1802) and Face Region Remeshing Method (p. 1820).

Unlike the radial basis function smoothing method, the diffusion-based smoothing method is not supported when the smoothing zone contains deforming conformal periodic boundaries and/or is a solid that has a moving wall.

12.6.2.1.2. Spring-Based Smoothing

For spring-based smoothing, the edges between any two mesh nodes are idealized as a network of interconnected springs. The initial spacings of the edges before any boundary motion constitute the equilibrium state of the mesh. A displacement at a given boundary node will generate a force proportional to the displacement along all the springs connected to the node. Using Hook's Law, the force on a mesh node can be written as

$$\vec{F}_i = \sum_j^{n_i} k_{ij} \left(\Delta\vec{x}_j - \Delta\vec{x}_i \right) \tag{12.6}$$

where $\Delta\vec{x}_i$ and $\Delta\vec{x}_j$ are the displacements of node i and its neighbor j, n_i is the number of neighboring nodes connected to node i, and k_{ij} is the spring constant (or stiffness) between node i and its neighbor j. The spring constant for the edge connecting nodes i and j is defined as

$$k_{ij} = \frac{k_{\text{fac}}}{\sqrt{\left|\vec{x}_i - \vec{x}_j\right|}} \tag{12.7}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where k_{fac} is the value you enter for **Spring Constant Factor** in the Mesh Smoothing Parameters Dialog Box (p. 5064).

At equilibrium, the net force on a node due to all the springs connected to the node must be zero. This condition results in an iterative equation such that

$$\Delta\vec{x}_i^{m+1} = \frac{\sum_j^{n_i} k_{ij}\Delta\vec{x}_j^{m}}{\sum_j^{n_i} k_{ij}} \tag{12.8}$$

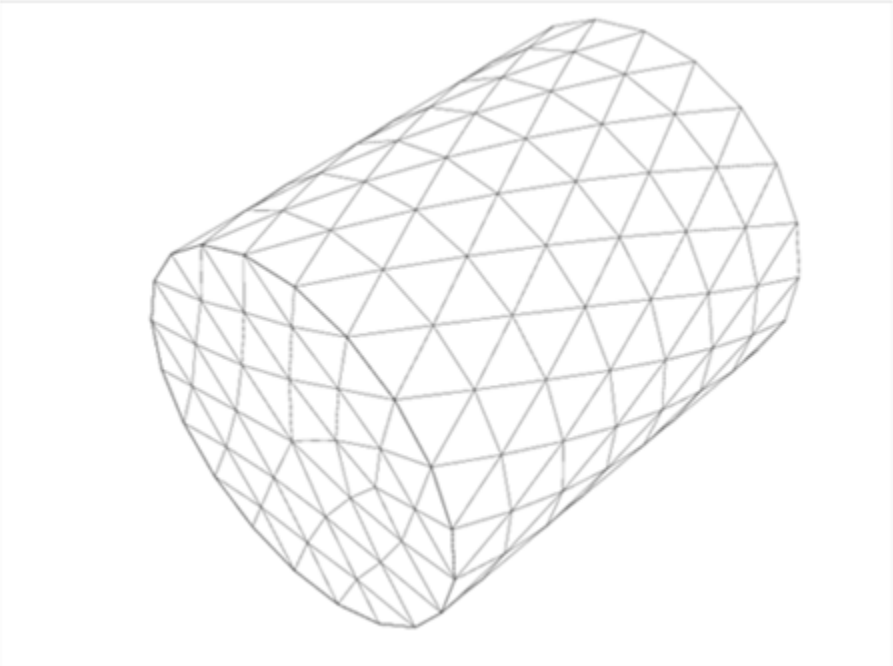
where m is the iteration number.

Since displacements are known at the boundaries (after boundary node positions have been updated), Equation 12.8 (p. 1793) is solved using a Jacobi sweep on all interior nodes. At convergence, the positions are updated such that

$$\vec{x}_i^{n+1} = \vec{x}_i^{n} + \Delta\vec{x}_i^{\text{converged}} \tag{12.9}$$

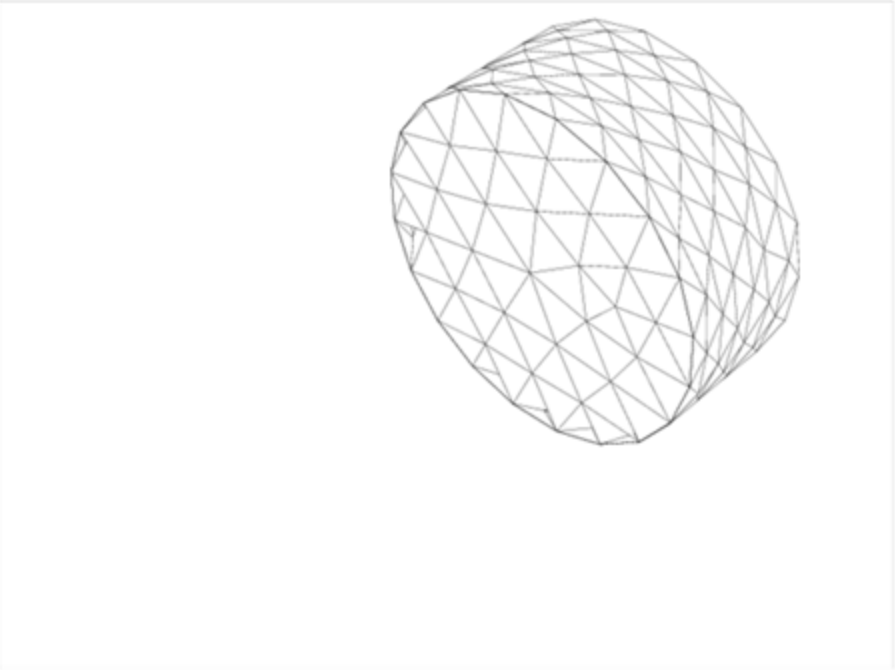
where $n+1$ and n are used to denote the positions at the next time step and the current time step, respectively. The spring-based smoothing is shown in Figure 12.21: Spring-Based Smoothing on Interior Nodes: Start (p. 1793) and Figure 12.22: Spring-Based Smoothing on Interior Nodes: End (p. 1794) for a cylindrical cell zone where one end of the cylinder is moving.

Figure 12.21: Spring-Based Smoothing on Interior Nodes: Start



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.22: Spring-Based Smoothing on Interior Nodes: End



You can control the spring stiffness by adjusting the value of the **Spring Constant Factor** between 0 and 1. A value of 0 indicates that there is no damping on the springs, and boundary node displacements have more influence on the motion of the interior nodes. A value of 1 imposes the default level of damping on the interior node displacements as determined by solving Equation 12.8 (p. 1793).

The effect of the **Spring Constant Factor** is illustrated in Figure 12.23: Interior Nodes Extend Beyond Boundary (Spring Constant Factor = 1) (p. 1795) and Figure 12.24: Interior Nodes Remain Within Boundary (Spring Constant Factor = 0) (p. 1795), which show the trailing edge of a NACA-0012 airfoil after a counter-clockwise rotation of 2.3° and the mesh is smoothed using the spring-based smoother but limited to 20 iterations. Degenerate cells (Figure 12.23: Interior Nodes Extend Beyond Boundary (Spring Constant Factor = 1) (p. 1795)) are created with the default value of 1 for the **Spring Constant Factor**, as the interior nodes extend beyond the moving boundary. However, the original mesh distribution (Figure 12.24: Interior Nodes Remain Within Boundary (Spring Constant Factor = 0) (p. 1795)) is recovered if the **Spring Constant Factor** is set to 0 (that is, no damping on the displacement of interior nodes near the airfoil surface).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.23: Interior Nodes Extend Beyond Boundary (Spring Constant Factor = 1)

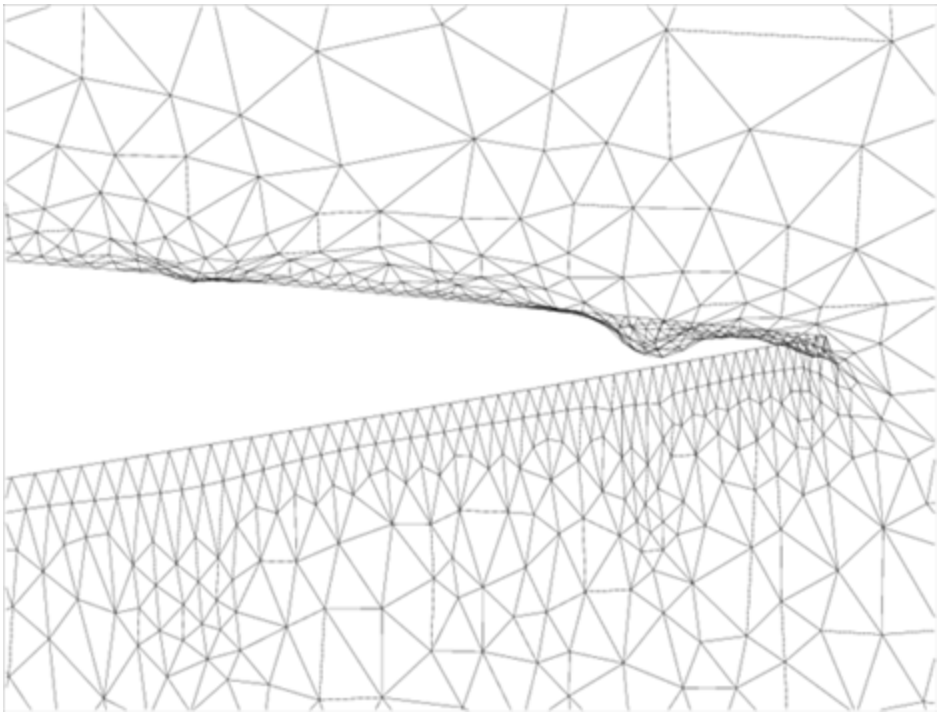


Figure 12.24: Interior Nodes Remain Within Boundary (Spring Constant Factor = 0)

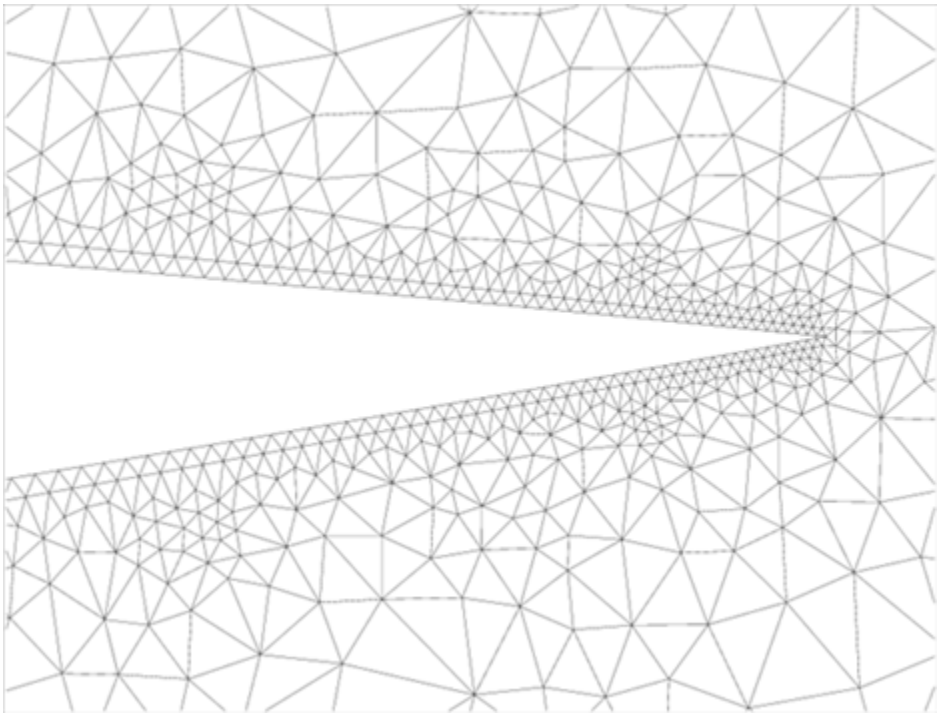


You can control the solution of Equation 12.8 (p. 1793) using the values of **Convergence Tolerance** and **Maximum Number of Iterations**. Ansys Fluent solves Equation 12.8 (p. 1793) iteratively during each time step until one of the following criteria is met:

- The specified number of iterations has been performed.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The solution is converged for that time step:

$$\left(\frac{\Delta\vec{x}^{m}_{rms}}{\Delta\vec{x}^{1}_{rms}}\right) < \text{convergence tolerance} \tag{12.10}$$

where $\Delta\vec{x}^{1}_{rms}$ is the interior and deforming nodes RMS displacement at the first iteration.

12.6.2.1.2.1. Applicability of the Spring-Based Smoothing Method

You can use the spring-based smoothing method to update any cell or face zone whose boundary is moving or deforming.

For non-tetrahedral cell zones (non-triangular in 2D), the spring-based method can be used when the following conditions are met:

- The boundary of the cell zone moves predominantly in one direction (that is, no excessive anisotropic stretching or compression of the cell zone).
- The motion is predominantly normal to the boundary zone.

If these conditions are not met, the resulting cells may have high skewness values, since not all possible combinations of node pairs in non-tetrahedral cells (or non-triangular in 2D) are idealized as springs. Polyhedral cells are particularly likely to become highly skewed with spring-based smoothing (regardless of whether the previous conditions are met), and so the radial basis function smoothing method is generally recommended for polyhedra (see Radial Basis Function Smoothing (p. 1798)).

By default, spring-based smoothing is enabled for all cell zones. This is reflected in the Mesh Smoothing Parameters Dialog Box (p. 5064), where **All** is selected from the **Elements** list. If you want to disable spring-based smoothing for cell zones that are not entirely composed of either tetrahedral or triangular cells, you can do that by selecting **Tet in Tet Zones** in 3D (or **Tri in Tri Zones** in 2D).

If you have mixed element zones and you do not want spring-based smoothing on all element types, you can enable spring-based smoothing on only the tetrahedral or triangular cells by selecting **Tet in Mixed Zones** in 3D (or **Tri in Mixed Zones** in 2D). Selection of smoothing elements in the Mesh Smoothing Parameters Dialog Box (p. 5064) applies by default to all cell zones that undergo spring-based smoothing. In order to have more precise control, it is possible to overwrite this global selection on individual dynamic cell zones (see Deforming Motion (p. 1878)). This gives, for example, the flexibility to suppress smoothing in zones where dynamic layering (see Dynamic Layering (p. 1805)) is used and allows at the same time smoothing of non-simplex (that is not tetrahedral or triangular) elements in other zones.

Unlike the radial basis function smoothing method, the spring-based smoothing method is not supported when the smoothing zone contains deforming conformal periodic boundaries and/or is a solid that has a moving wall.

12.6.2.1.3. Linearly Elastic Solid Based Smoothing Method

With mesh smoothing based on the linearly elastic solid model, the mesh motion is governed by the following set of equations.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\begin{aligned}&\nabla\cdot\boldsymbol{\sigma}\left(\vec{y}\right)=\mathbf{0}\\&\boldsymbol{\sigma}\left(\vec{y}\right)=\lambda\left(tr\boldsymbol{\varepsilon}\left(\vec{y}\right)\right)\mathbf{I}+2\mu\boldsymbol{\varepsilon}\left(\vec{y}\right)\\&\boldsymbol{\varepsilon}\left(\vec{y}\right)=\tfrac{1}{2}\left(\nabla\vec{y}+\left(\nabla\vec{y}\right)^{T}\right)\end{aligned} \tag{12.11}$$

where $\boldsymbol{\sigma}$ is the stress tensor, $\boldsymbol{\varepsilon}$ is the strain tensor, and $\vec{y}$ is the mesh displacement. For the solution of Equation 12.11 (p. 1797) only the ratio between the shear modulus, μ, and Lamé's first parameter, λ, matters. This ratio is parameterized through Poisson's ratio (ν):

$$\nu=\frac{1}{2\left(1+{}_{\mu/\lambda}\right)} \tag{12.12}$$

You define this property through the **Poisson's Ratio** field in the Mesh Smoothing Parameters Dialog Box (p. 5064). Note that the linearly elastic solid mesh smoothing model supports constant material properties only. The permissible range for **Poisson's Ratio** is between -1.0 and 0.5.

The boundary conditions for Equation 12.11 (p. 1797) are obtained from the user-prescribed or computed (in the case of six DOF motion) boundary deformations. These imposed deformations are transferred into the interior of the deforming mesh as if the mesh was a linearly elastic solid with the given material properties. On deforming boundaries you can either specify a geometry along which the mesh can slide, or leave the geometry unspecified. If a geometry is specified for the deforming boundary, then the boundary conditions are such that the deformation normal to the boundary vanishes and the stress tangential to the boundary is zero. If the geometry of the deforming boundary is unspecified, then the deforming boundary can also deform in the normal direction and the boundary conditions are such that the traction is zero in all directions. See Deforming Motion (p. 1878) for details of how to specify geometry on deforming zones.

The linear system in Equation 12.11 (p. 1797) is solved using a finite element discretization and the mesh displacements for the interior and deforming boundary nodes are obtained directly at the nodes. The accuracy to which the linear system is solved can be controlled by the **Maximum Number of Iterations** and the **Relative Convergence Tolerance**.

You can specify the solution method used by the linear solver for the linearly elastic solid mesh smoothing calculations. By default, the **CG** (conjugate gradient) method is selected from the **AMG Stabilization** drop-down list. This method should be faster in this context than the other available methods, as it takes advantage of the symmetry of the matrix used in the linear systems of equations of finite-element-based mesh smoothing. If divergence is detected with CG, then the generalized minimal residual (GMRES) method will be used for an iteration as a fallback, and you will be informed in the console that a finite-element-based mesh smoothing coupled equation is being stabilized to enhance linear solver robustness. In rare cases, the CG method may result in the generation of negative volume cells; you may be able to avoid this by increasing the **Maximum Number of Iterations** from the default of 50 to a value in the range of 200–500.

If the CG method continues to generate negative volume cells with a higher number of inner iterations or if you repeatedly see console messages that say the GMRES fallback is being used, it is recommended that you select **GMRES** from the **AMG Stabilization** drop-down list. Note that the GMRES method is more robust than the CG method, especially for high-aspect-ratio meshes; but it is also more demanding in terms of memory usage and solver time.

Note that this drop-down list also allows you to select the **BCGSTAB** (bi-conjugate gradient stabilized) method; like the CG method, BCGSTAB falls back to the GMRES method for an iteration when divergence is detected.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can enable printing of smoothing residuals in the console by entering 1 for the **Verbosity**.

For simulations with periodic or quasi-periodic motion, you can improve the mesh quality consistency by specifying that the linearly elastic solid mesh smoothing uses a reference position, as described in Smoothing from a Reference Position (p. 1800).

12.6.2.1.3.1. Applicability of the Linearly Elastic Solid Based Smoothing Method

Most of the properties and limitations discussed for diffusion-based smoothing (Applicability of the Diffusion-Based Smoothing Method (p. 1792)) also apply to the linearly elastic solid model, particularly the mesh quality degradation for rotational motions. The linearly elastic solid model is computationally more expensive than diffusion-based smoothing, but for some meshes and mesh motions preserves the mesh quality better.

The current implementation with constant material properties can be a limitation compared with diffusion-based smoothing with non-uniform diffusivity. In cases with rotational boundary motion and sharp corners it may be advantageous to use radial basis function smoothing, or perhaps diffusion-based smoothing with boundary-distance-dependent diffusivity.

The linearly elastic solid smoothing method provides you the option to leave the geometry of deforming face zones unspecified. This option is not available for any other smoothing method except for the radial basis function method.

The linearly elastic solid smoothing method supports triangular and quadrilateral elements in 2D and tetrahedral, hexahedral, wedge, and pyramid cells in 3D. It cannot be applied if the deforming cell zone contains polyhedral cells or hanging nodes. In such cases radial basis function smoothing is recommended.

Linearly elastic solid smoothing is not compatible with the boundary layer smoothing method or the face region remeshing method. For more information about these methods, see Boundary Layer Smoothing Method (p. 1802) and Face Region Remeshing Method (p. 1820).

Unlike the radial basis function smoothing method, the linearly elastic solid smoothing method is not supported when the smoothing zone contains deforming conformal periodic boundaries and/or is a solid that has a moving wall.

12.6.2.1.4. Radial Basis Function Smoothing

When the smoothing is based on a radial basis function interpolation, Fluent solves for a displacement field that satisfies the displacements at boundaries with prescribed motion, and then interpolates the displacements onto all other nodes in the interior and at the deforming boundaries. As with the other available smoothing methods, deforming boundaries are boundaries where the nodes are allowed to slide tangentially.

Radial basis function smoothing has the following advantages:

- Compared to the other available smoothing methods, it is particularly well suited for motions that undergo rotation. On average, more rotational motion can be absorbed by the mesh with radial basis function smoothing before the mesh quality degenerates.
- Unlike linearly elastic solid based smoothing, it is available for adapted meshes with hanging nodes or polyhedra elements.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Unlike diffusion smoothing, it is robust for polyhedral elements.
- It is the only smoothing method that is supported when:
  - the smoothing zone contains deforming conformal periodic boundaries.
  - the smoothing zone is a solid that has a moving wall, as may be the case in a simulation that models ablation or erosion / accretion (see Thermal Conditions for Two-Sided Walls (p. 1450) and Particle Erosion Coupled with Dynamic Meshes (p. 2790), respectively). Note that the ablation or erosion / accretion must be set up on the fluid side of the coupled wall.

On deforming boundaries, you can either specify a geometry (such as a plane, cylinder, and so on) along which the mesh can slide, or leave the geometry unspecified so that the nodes are allowed to move in any direction. See Deforming Motion (p. 1878) for details of how to define the geometry for deforming zones. The ability to leave the geometry of deforming face zones unspecified is not available for any other smoothing method except for the radial basis function smoothing method and the linearly elastic solid smoothing method. Note that if you have a non-conformal interface where both of the interface boundaries are defined as deforming dynamic zones with unspecified geometry, then Fluent will ensure that the two interface zones stay connected (by projecting one of the interface zones onto the other); such behavior is only supported with radial basis function smoothing, and then only if the same cell zone is on either side of the non-conformal interface.

Advanced settings are available for radial basis function smoothing in the Mesh Smoothing Parameters Dialog Box (p. 5064). The accuracy to which the displacement field is solved can be controlled by the **Relative Convergence Tolerance**: if the smoothing produces negative volume cells, you can decrease this value to try to address the problem; if the solution is running well, you can increase the value to speed up the calculation. You can also set the **Verbosity** to 1 if you want to print the absolute tolerance computed (based on your specified relative tolerance) in the console during the calculation. If you want to limit the amount of the domain that is smoothed to only those cells that are close to the moving boundary zone(s), you can enable the **Local Smoothing** option (for details, see Local Smoothing with the Radial Basis Function Smoothing Method (p. 1800)). Finally, you can specify that the smoothing uses a reference position (as described in Smoothing from a Reference Position (p. 1800)), which can improve mesh quality consistency when performing many cycles of periodic or quasi-periodic motion for stationary or moving meshes.

If you want to smooth the entire mesh but would like to take advantage of the boundary layer smoothing that is done as part of the **Local Smoothing** option (and hence retain the shape of the boundary layers as much as possible), you can make sure that the **Local Smoothing** option is disabled and use the following text command:

`define → dynamic → controls → smoothing-parameters → smooth-boundary-layers-with-adjacent-zone?`

Note the following limitations:

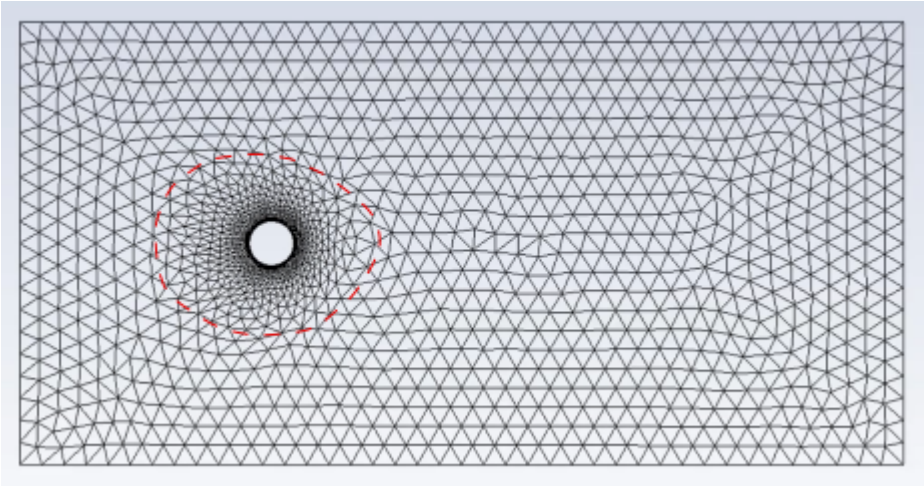
- The performance of radial basis function smoothing does not scale as well as the other smoothing methods when running distributed memory on a cluster.
- Radial basis function smoothing is not compatible with the boundary layer smoothing method. For more information about this method, see Boundary Layer Smoothing Method (p. 1802).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12.6.2.1.4.1. Local Smoothing with the Radial Basis Function Smoothing Method

As mentioned in the previous section, you can enable the **Local Smoothing** option in the Mesh Smoothing Parameters Dialog Box (p. 5064) when using the radial basis function smoothing method, so that only the portion of the mesh adjacent to the moving boundary zone is smoothed. This ensures that the mesh away from the moving boundary remains undisturbed by the smoothing, and decreases the computational time required for smoothing. The following figure provides an example of such local smoothing: the circular boundary zone is moving to the right, and only those cells within the red dotted line are smoothed, while the rest of the domain is unaffected.

Figure 12.25: An Example of Where Local Smoothing is Applied



Note:

Depending on the amplitude of motion, it might be necessary to enable remeshing along with the local smoothing, as the motion is now absorbed in a smaller region. For details, see Remeshing (p. 1809).

If there are boundary layers adjacent to the moving zone, they are smoothed before and independently of the local smoothing region, ensuring that they retain their shape as much as possible. The portion of the mesh smoothed by the local smoothing is then evaluated starting from the edge of the boundary layers. When identifying which cells are boundary layers, Fluent searches for prismatic cells (that is, hexahedral cells or wedge or polyhedral cells that have the same number of nodes on the top and bottom faces relative to the boundary normal) that are in layers adjacent to a boundary zone.

12.6.2.1.5. Smoothing from a Reference Position

When the mesh smoothing is based on diffusion, the linearly elastic solid model, or a radial basis function interpolation, you have the option of specifying that the smoothing uses a reference position. This can be helpful when performing many cycles of periodic or quasi-periodic motion for stationary or moving meshes; for example, turbomachinery rotors with blade flutter. When you ensure that the smoothing is always done from the same reference position, the mesh quality may remain more consistent from cycle to cycle.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To use this feature, enable the **Smoothing From Reference Position** option in the Mesh Smoothing Parameters Dialog Box (p. 5064). Note this option is enabled by default during the calculation if the case includes a cell zone that has **Frame Motion** or **Mesh Motion** enabled with a nonzero rotational velocity and that is also defined as a deforming dynamic mesh zone. This option is not available if the **Layering** and/or **Remeshing** options are enabled in the **Dynamic Mesh** task page, or if automatic adaption criteria is activated in the **Manage Adaption Criteria** dialog box.

The reference position is saved the first time you perform smoothing after enabling this option. It is recommended that you do not save your case / data files in the legacy format (that is, with the `file/cff-file?` text command set to `no`): the reference position is not saved in this format, and so restarting from a `.cas` file will imply that a different reference position is used after restart. This still provides the benefit of consistent quality, but the resulting meshes might be slightly different from a continuous run. The impact of such slight mesh changes on the solution results will be small, except for cases with a high degree of mesh dependence; if you must use a legacy case file, it is recommended that you evaluate the original mesh to ensure that it is suitable for the problem.

12.6.2.1.6. Laplacian Smoothing Method

Laplacian smoothing is the most commonly used and the simplest mesh smoothing method. This method adjusts the location of each mesh vertex to the geometric center of its neighboring vertices. This method is computationally inexpensive but it does not guarantee an improvement on mesh quality, since repositioning a vertex by Laplacian smoothing can result in poor quality elements. To overcome this problem, Ansys Fluent only relocates the vertex to the geometric center of its neighboring vertices if and only if there is an improvement in the mesh quality (that is, the skewness has been improved).

This improved Laplacian smoothing can be enabled on deforming boundaries only (that is, the zone with triangular elements in 3D and zones with linear elements in 2D). The computation of the node positions works as follows:

$$\overrightarrow{\overline{x}}_i^m = \frac{\sum_j^{n_i} \vec{x}_i^m}{n_i} \tag{12.13}$$

where $\overrightarrow{\overline{x}}_i^m$ is the averaged node position of node i at iteration m, $\vec{x}_j^m$ is the node position of neighbor node of $\vec{x}_i^m$ at iteration m, and n_i is the number nodes neighboring node i. The new node position $\vec{x}_i^{m+1}$ is then computed as follows:

$$\vec{x}_i^{m+1} = \vec{x}_i^m (1-\beta) + \overrightarrow{\overline{x}}_i^m \beta \tag{12.14}$$

where β is the Laplace node relaxation factor.

This update only happens if the maximum skewness of all faces adjacent to $\vec{x}_i^{m+1}$ is improved in comparison to $\vec{x}_i^m$.

For details on applying Laplacian smoothing to either a cell zone (with 2.5D remeshing) or a face zone, see Smoothing Methods (p. 1784) or Deforming Motion (p. 1878), respectively.

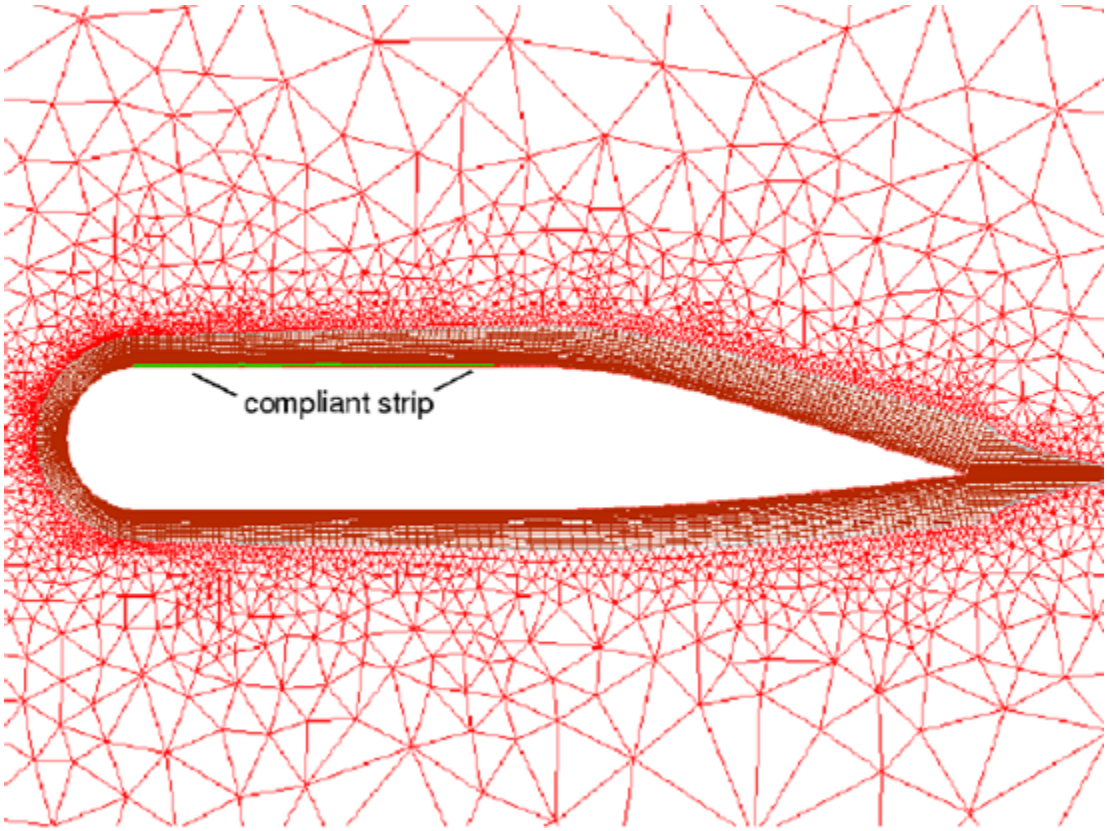
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12.6.2.1.7. Boundary Layer Smoothing Method

The boundary layer smoothing method is used to deform the boundary layer mesh during a moving-deforming mesh simulation. For cases that apply mesh motion (either **Rigid Body** or **User-Defined**) to a face zone with adjacent boundary layers, the boundary layers can be made to deform accordingly by enabling **Deform Adjacent Boundary Layer with Zone** for the face zone in the Dynamic Mesh Zones Dialog Box (p. 5086). With boundary layer smoothing enabled, the nodal coordinates of each cell in the boundary layer zone are updated with the same displacement vector as the corresponding nodes on the underlying face zone. The boundary layer smoothing method can be applied to boundary layer zones of all mesh types (that is, wedges and hexahedra in 3D, quadrilaterals in 2D).

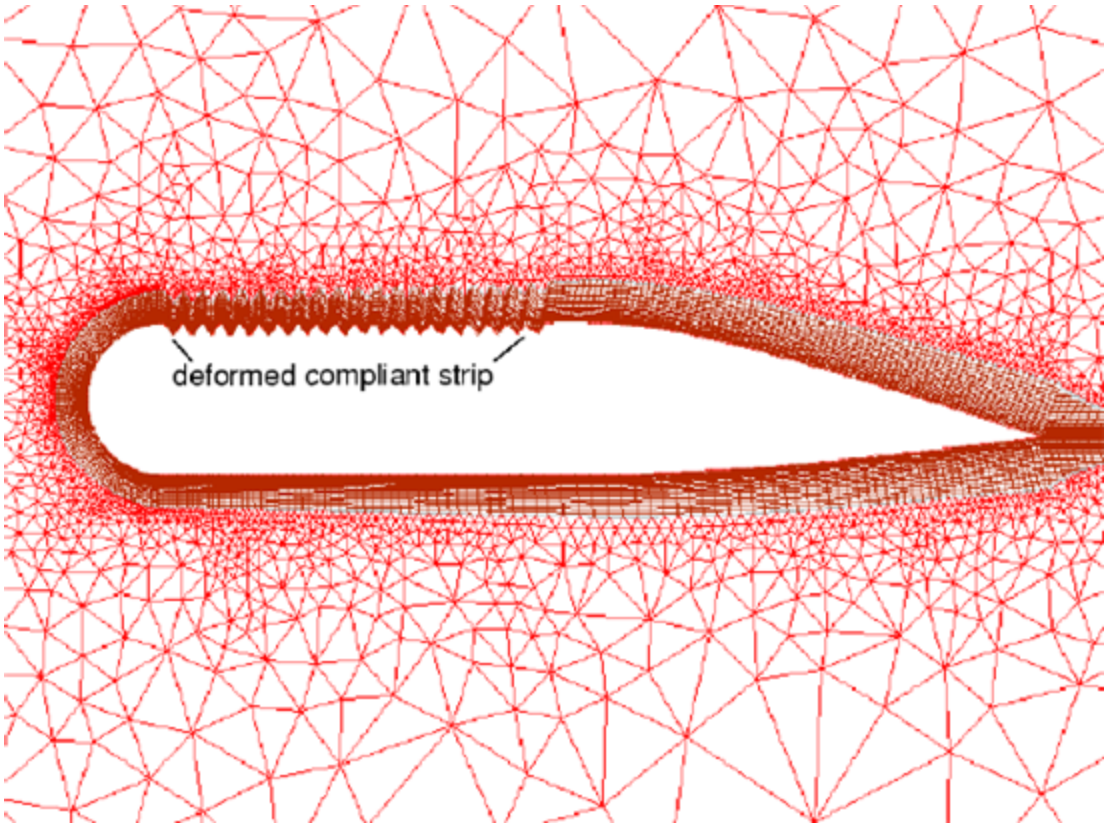
Consider the example below, where a UDF of the form `DEFINE_GRID_MOTION` provides the moving-deforming mesh model with the locations of the nodes located on the compliant strip on an idealized airfoil. The node motion varies sinusoidally in time and space (compare Figure 12.26: The Undeformed Mesh (p. 1802) with Figure 12.27: The Deformed Mesh (p. 1803)).

Figure 12.26: The Undeformed Mesh



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

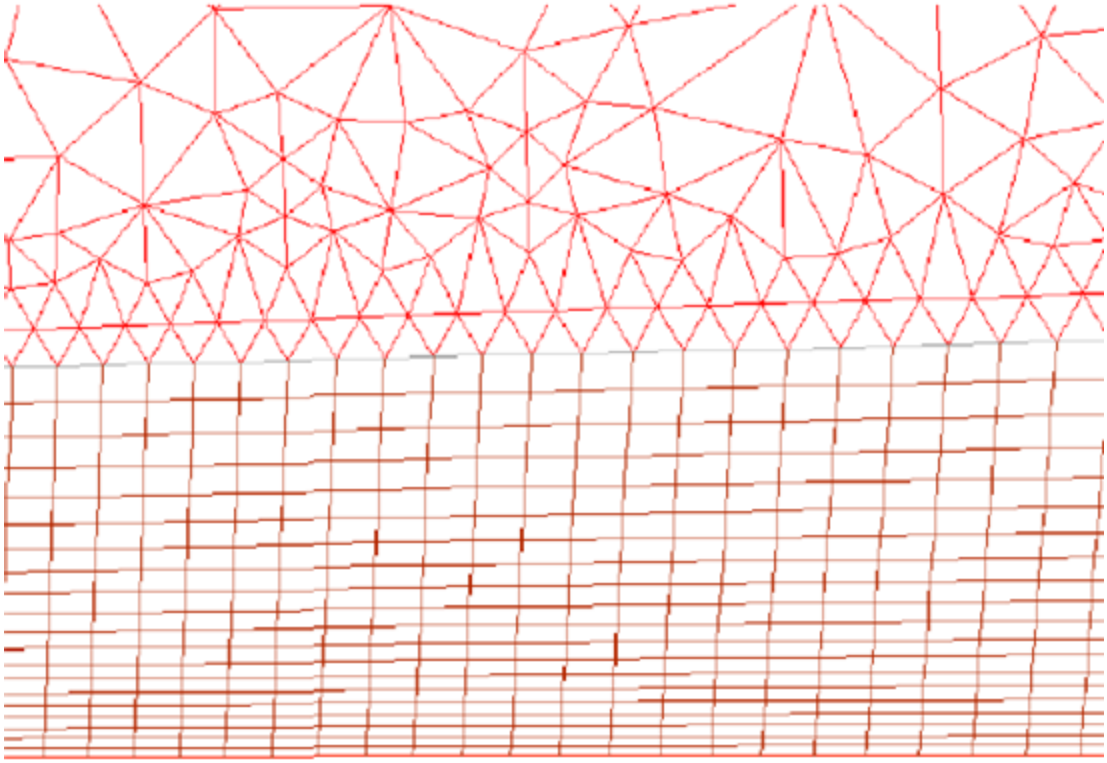
Figure 12.27: The Deformed Mesh



As a result of the boundary layer smoothing, the cells adjacent to the deforming wall are also deformed in order to preserve the quality of boundary layer zone. If you compare Figure 12.28: Zooming into the Undeformed Compliant Strip (p. 1804) with Figure 12.29: Zooming into the Deformed Compliant Strip with Boundary Layer Smoothing Applied (p. 1805), you can see how the boundary layer cells have been deformed according to the motion of the nodes on the compliant strip.

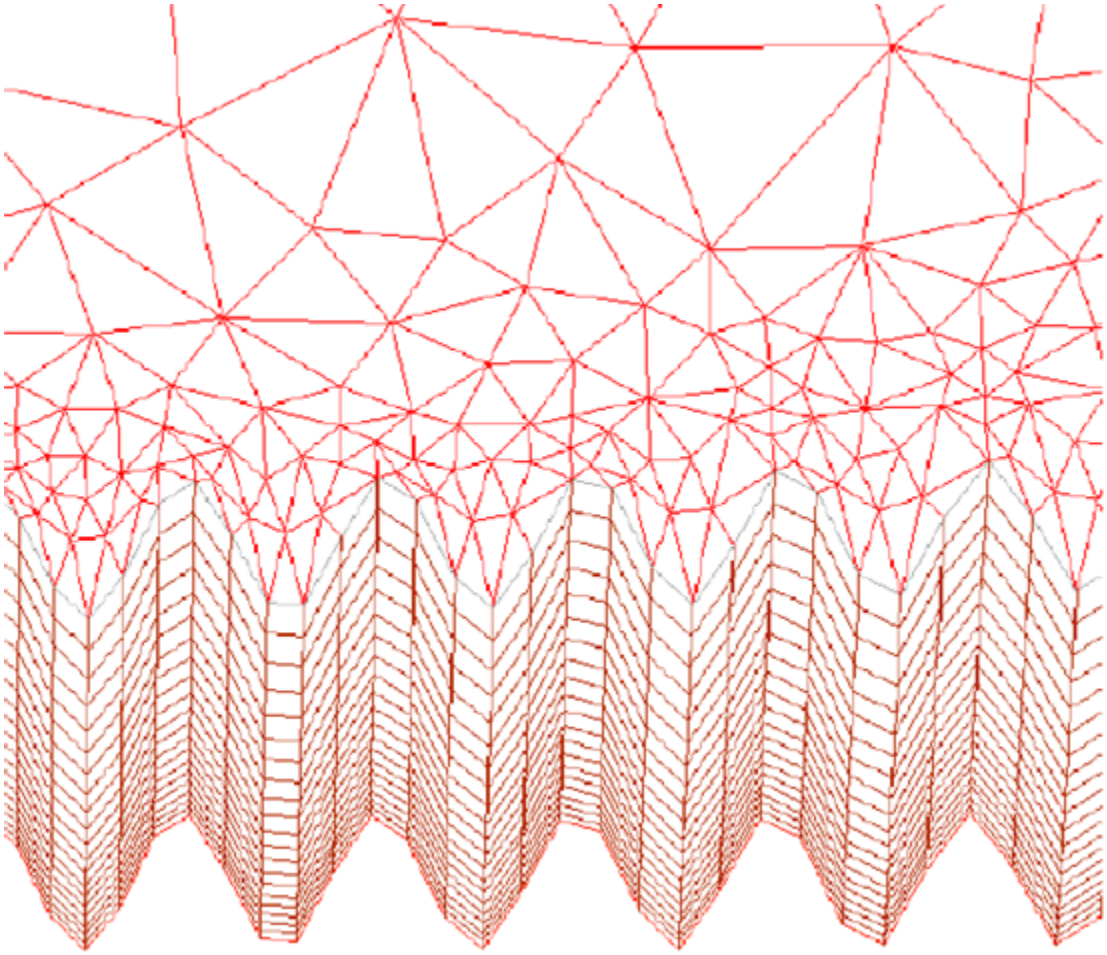
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.28: Zooming into the Undeformed Compliant Strip



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.29: Zooming into the Deformed Compliant Strip with Boundary Layer Smoothing Applied



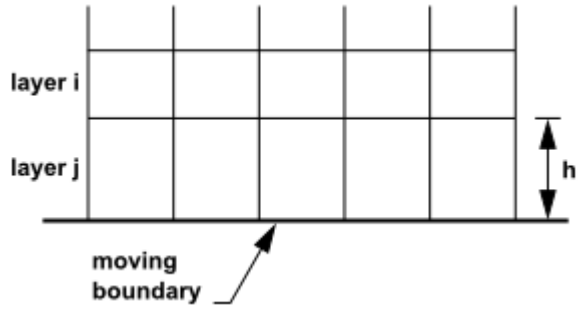
Typically, the boundary layer smoothing method preserves the height of the boundary layer cells adjacent to the deformed face zone. However, note that this approach is primarily intended for translational motion. If the faces undergo substantial rotation, the boundary layer cells may become skewed. See Smoothing Methods (p. 1784) and Specifying Boundary Layer Deformation Smoothing (p. 1883) for details about enabling smoothing and defining a moving and deforming boundary layer, respectively. Note that boundary layer smoothing is compatible with spring-based smoothing only. It cannot be used with diffusion-based smoothing, linearly elastic solid smoothing, or radial basis function smoothing. Also note that the boundary layer smoothing method will work whether or not you have segregated the boundary layer elements into a separate cell zone.

12.6.2.2. Dynamic Layering

In prismatic (polyhedral, hexahedral, and/or wedge in 3D, or quadrilateral in 2D) mesh zones, you can use dynamic layering to add or remove layers of cells adjacent to a moving boundary, based on the height of the layer adjacent to the moving surface. The dynamic mesh model in Ansys Fluent allows you to specify an ideal layer height on each moving boundary. The layer of cells adjacent to the moving boundary (layer j in Figure 12.30: Dynamic Layering (p. 1806)) is split or merged with the layer of cells next to it (layer i in Figure 12.30: Dynamic Layering (p. 1806)) based on the height (h) of the cells in layer j.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.30: Dynamic Layering



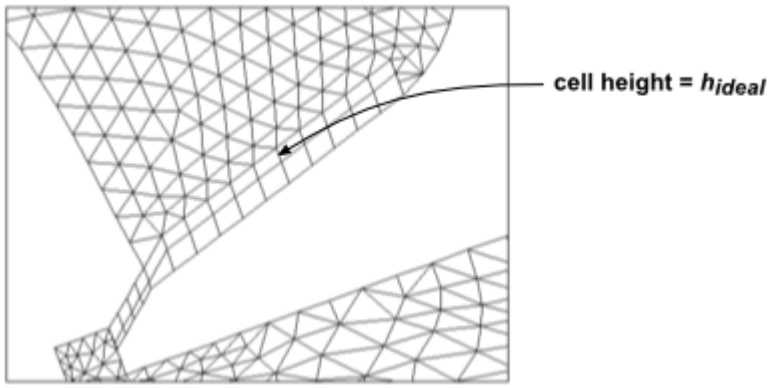
If the cells in layer j are expanding, the cell heights are allowed to increase until

$$h_{min} > (1+\alpha_s)h_{ideal} \tag{12.15}$$

where h_{min} is the minimum cell height of cell layer j, h_{ideal} is the ideal cell height, and α_s is the layer split factor. Note that Ansys Fluent allows you to define h_{ideal} as either a constant value or a value that varies as a function of time or crank angle. When the condition in Equation 12.15 (p. 1806) is met, the cells are split based on the specified layering option. This option can be height based or ratio based.

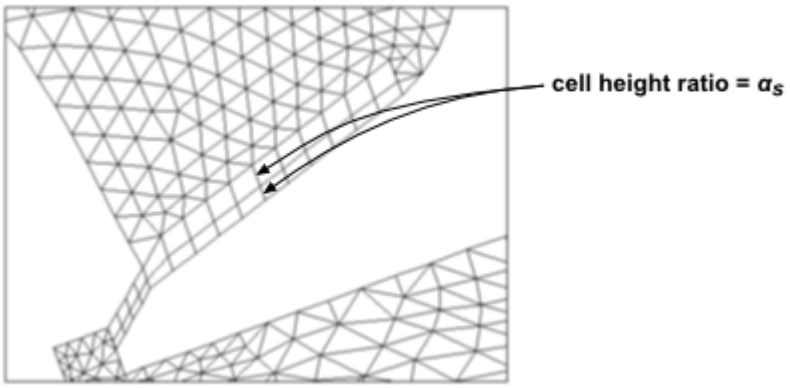
With the height-based option, the cells are split to create a layer of cells with constant height h_{ideal} and a layer of cells of height $h-h_{ideal}$. With the ratio-based option the cells are split such that, locally, the ratio of the new cell heights to old cell heights is exactly α_s everywhere. Figure 12.31: Results of Splitting Layer with the Height-Based Option (p. 1806) and Figure 12.32: Results of Splitting Layer with the Ratio-Based Option (p. 1807) show the result of splitting a layer of cells above a valve geometry using the height-based and ratio-based option.

Figure 12.31: Results of Splitting Layer with the Height-Based Option



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.32: Results of Splitting Layer with the Ratio-Based Option



If the cells in layer j are being compressed, they can be compressed until

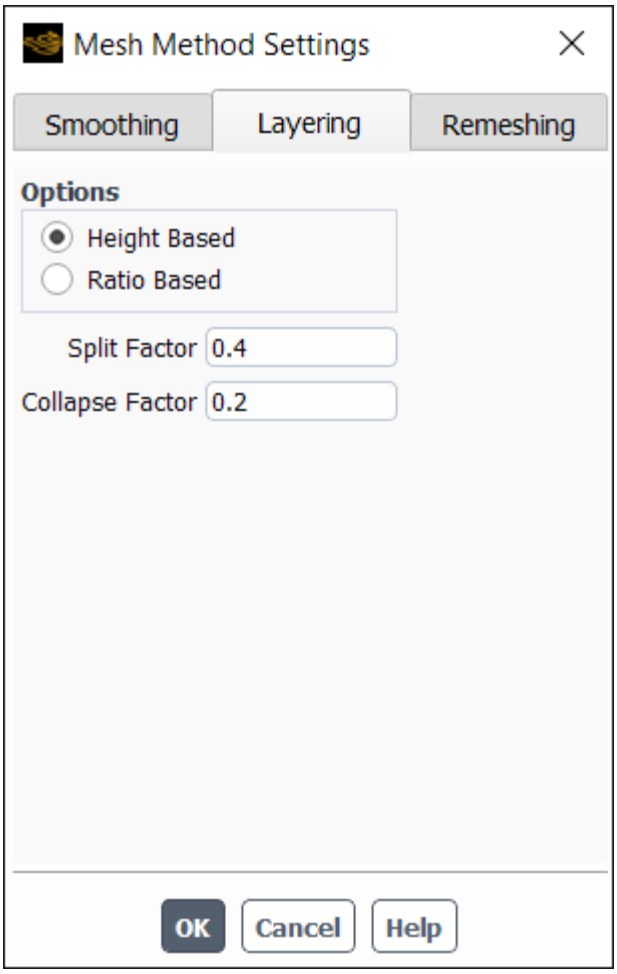
$$h_{min} < \alpha_c h_{ideal} \tag{12.16}$$

where α_c is the layer collapse factor. When this condition is met, the compressed layer of cells is merged into the layer of cells above the compressed layer in Figure 12.30: Dynamic Layering (p. 1806); that is, the cells in layer j are merged with those in layer i.

To enable dynamic layering, enable the **Layering** option under **Mesh Methods** in the Dynamic Mesh Task Page (p. 5057) (Figure 12.33: The Layering Tab in the Mesh Method Settings Dialog Box (p. 1808)). The layering control is specified in the **Layering** tab, which can be displayed by clicking **Settings...**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.33: The Layering Tab in the Mesh Method Settings Dialog Box



You can control how a cell layer is split by specifying either **Height Based** or **Ratio Based** under **Options**. Note that for **Height Based**, the height of the cells in a particular new layer will be constant, but you can choose to have this height vary from layer to layer as a function of time or crank angle when you specify the **Cell Height** in the **Dynamic Mesh Zones** dialog box (see Specifying the Motion of Dynamic Zones (p. 1872) for further details).

The **Split Factor** and **Collapse Factor** (α_s in Equation 12.15 (p. 1806) and α_c in Equation 12.16 (p. 1807), respectively) are the factors that determine when a layer of prismatic cells (polyhedra, hexahedra, or wedges in 3D, or quadrilaterals in 2D) that is next to a moving boundary is split or merged with the adjacent cell layer, respectively.

12.6.2.2.1. Applicability of the Dynamic Layering Method

You can use the dynamic layering method to split or merge cells adjacent to any moving boundary provided the following conditions are met:

- All cells adjacent to the moving face zone are prismatic and either polyhedra, hexahedra, or wedges (quadrilaterals in 2D), even though the cell zone may contain mixed cell shapes.
- The cell layers must be completely bounded by one-sided face zones, except when sliding interfaces are used (see Applicability of the Face Region Remeshing Method (p. 1824)).

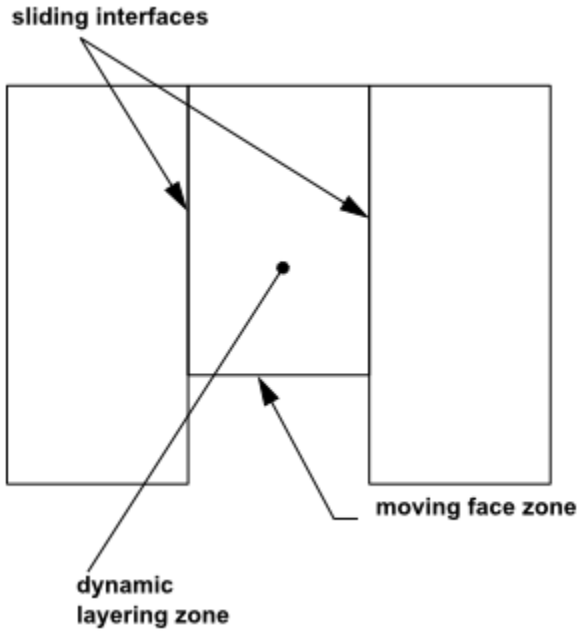
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Note that you cannot use the dynamic layering method in conjunction with adaption in almost all cases. For more information on the available adaption methods, see Hanging Node Adaption and Polyhedral Unstructured Mesh Adaption in the Theory Guide.

If the moving boundary is an internal zone, cells on both sides (possibly with different ideal cell layer heights) of the internal zone are considered for dynamic layering.

If you want to use dynamic layering on cells adjacent to a moving wall that do not span from boundary to boundary, you must separate those cells that are involved in the dynamic layering and use the sliding interfaces capability in Ansys Fluent to transition from the deforming cells to the adjacent non-deforming cells (see Figure 12.34: Use of Sliding Interfaces to Transition Between Adjacent Cell Zones and the Dynamic Layering Cell Zone (p. 1809)). For a moving interior face, the zones must be separated such that they are either expanding or collapsing on the same side. No one zone can consist of both expanding and collapsing layers.

Figure 12.34: Use of Sliding Interfaces to Transition Between Adjacent Cell Zones and the Dynamic Layering Cell Zone



12.6.2.3. Remeshing

When the boundary displacement is large compared to the local cell sizes, the cell quality can deteriorate or the cells can become degenerate if only mesh smoothing is used. This will invalidate the mesh (for example, result in negative cell volumes) and consequently, will lead to convergence problems when the solution is updated to the next time step.

To circumvent this problem, Ansys Fluent can agglomerate cells that violate the skewness or size criteria and locally remesh the agglomerated cells or faces. If the new cells or faces satisfy the skewness criterion, the mesh is locally updated with the new cells (with the solution interpolated from the old cells). Otherwise, the new cells are discarded and the old cells are retained.

When defining the remeshing settings for your dynamic zones, it is recommended that you use unified remeshing (the default), which applies an algorithm that combines aspects of a variety of remeshing methods and by default attempts to maintain the initial mesh size distribution even as

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the mesh moves. This simplifies the setup and can provide increased robustness, especially for parallel simulations. It should be noted that such unified remeshing is applied to triangular or tetrahedral cells and can produce wedge cells in 3D boundary layer meshes. As an alternative, you can use methods-based remeshing, which allows you to selectively enable the following options, each of which is suitable for particular kinds of cell types:

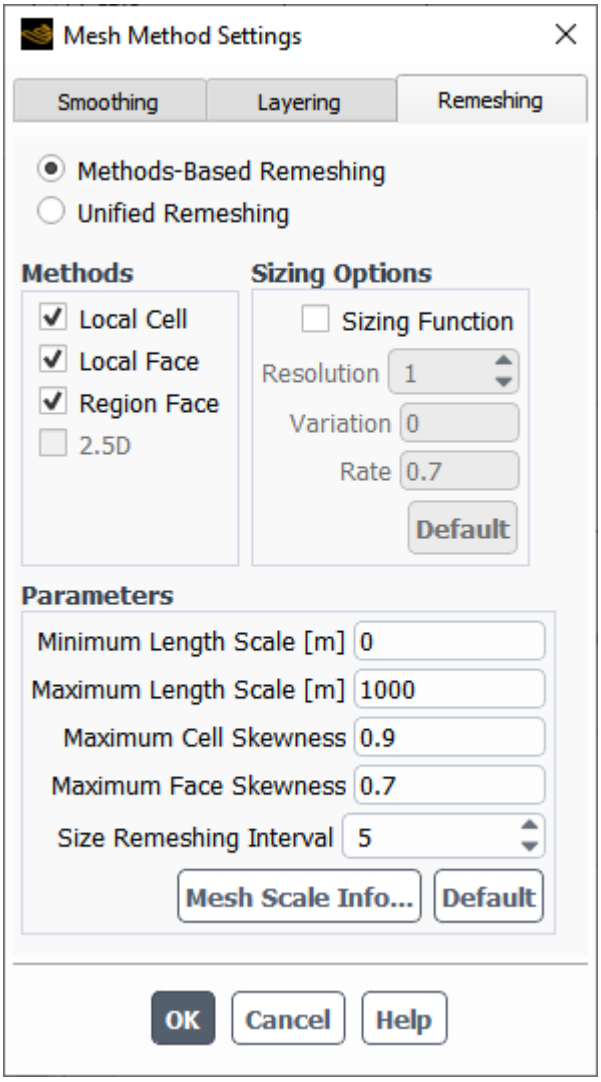
- The local cell remeshing method only affects triangular and tetrahedral cell types in the mesh (that is, in mixed cell zones the non-triangular/tetrahedral cells are skipped).
- The local face remeshing method is available in 3D only and can remesh tetrahedral cells and wedge cells in boundary layer meshes.
- The zone remeshing method replaces all cell types with triangular and tetrahedral cells (in 2D and 3D domains, respectively), and can remesh and produce wedge cells in 3D boundary layer meshes.
- The face region remeshing method is applied to triangular cells in 2D, and tetrahedral cells in 3D. In 3D domains, the face region remeshing method can also remesh and produce wedge cells in 3D boundary layer meshes.
- The 2.5D remeshing method only works on hexagonal meshes or wedge cells extruded from triangular surface elements.

To apply remeshing, enable the **Remeshing** option under **Mesh Methods** in the Dynamic Mesh Task Page (p. 5057) (Figure 12.13: The Dynamic Mesh Task Page (p. 1783)). Click the **Settings...** button to open the **Mesh Method Settings** dialog box, where you can select either **Methods-Based Remeshing** or **Unified Remeshing** in the **Remeshing** tab (Figure 12.35: The Remeshing Tab in the Mesh Method Settings Dialog Box for Methods-Based Remeshing (p. 1811)) and revise the options / parameters or the advanced settings.

For **Methods-Based Remeshing**, you can view the vital statistics of your mesh by clicking the **Mesh Scale Info...** button at the bottom of the Mesh Method Settings Dialog Box (p. 5060). This button opens the Mesh Scale Info Dialog Box (p. 5067), where you can view the minimum and maximum length scale values, as well as the maximum cell and face skewness values.

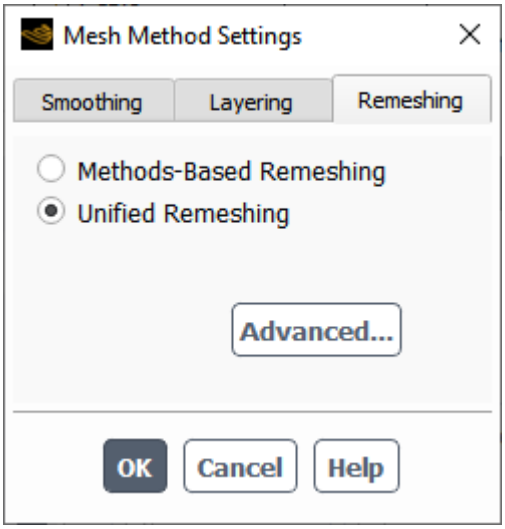
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.35: The Remeshing Tab in the Mesh Method Settings Dialog Box for Methods-Based Remeshing



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.36: The Remeshing Tab in the Mesh Method Settings Dialog Box for Unified Remeshing



For details, see the following sections:

12.6.2.3.1. Methods-Based Remeshing

12.6.2.3.2. Unified Remeshing

12.6.2.3.1. Methods-Based Remeshing

When **Methods-Based Remeshing** is selected in the **Remeshing** tab of the **Mesh Method Settings** dialog box, you can selectively enable the following methods:

12.6.2.3.1.1. Local Remeshing Method

12.6.2.3.1.2. Cell Zone Remeshing Method

12.6.2.3.1.3. Face Region Remeshing Method

12.6.2.3.1.4. 2.5D Surface Remeshing Method

12.6.2.3.1.1. Local Remeshing Method

Using the local remeshing method (that is, local cell remeshing, with or without local face remeshing), Ansys Fluent marks cells based on cell skewness and minimum and maximum length scales as well as an optional sizing function.

Ansys Fluent evaluates each cell and marks it for remeshing if it meets one or more of the following criteria:

- It has a skewness that is greater than a specified maximum skewness.
- It is smaller than a specified minimum length scale.
- It is larger than a specified maximum length scale.
- Its height does not meet the specified length scale (at moving face zones, for example, above a moving piston).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If local remeshing is not able to reduce the maximum cell skewness sufficiently, then the cell zone remeshing method is used to automatically remesh all of the cells in the cell zone, as well as the faces of all adjacent deforming dynamic face zones (see Cell Zone Remeshing Method (p. 1820) for details). The maximum allowable cell skewness is set to be 0.98 by default. The cell zone remeshing method gives the mesher more flexibility to create a new mesh of better quality than the local cell remeshing method. The automatic remeshing of cell zones can be disabled using the following text command:

`define` → `dynamic-mesh` → `controls` → `remeshing-parameter` → `zone-remeshing`

12.6.2.3.1.1.1. Local Cell Remeshing Method

As previously mentioned, in local cell remeshing, Ansys Fluent agglomerates cells based on skewness, size, and height (adjacent moving face zones) prior to the movement of the boundary. The size criteria are specified with **Minimum Length Scale** and **Maximum Length Scale**. Cells with length scales below the minimum length scale and above the maximum length scale are marked for remeshing. The value of **Maximum Cell Skewness** indicates the desired skewness of the mesh. By default, the **Maximum Cell Skewness** is set to 0.9 for 3D simulations and 0.7 for 2D simulations. Cells with skewness above the maximum skewness are marked for remeshing.

The marking of cells based on skewness is done at every time step when the local remeshing method is enabled. However, marking based on size and height is performed between the specified **Size Remeshing Interval** since the change in cell size distribution is typically small over one time step.

Note that you should edit the fields in the **Parameters** group box, as the initial values are unlikely to produce your desired outcome. Clicking **Default** will define values that are based on your particular mesh and that should represent a reasonable starting point, and you can then adjust them as needed. After you click the **Default** button, it will then change to be a **Reset** button, which can be used to return to the prior values.

By default, Ansys Fluent replaces the agglomerated cells only if the quality of the remeshed cells has improved.

Note that you cannot use the local cell remeshing method in conjunction with adaption. For more information on the available adaption methods, see Hanging Node Adaption and Polyhedral Unstructured Mesh Adaption in the Theory Guide.

12.6.2.3.1.1.2. Local Face Remeshing Method

The local face remeshing method only applies to 3D geometries. You can apply this method to the boundaries of deforming or user-defined zone types, so that Ansys Fluent will mark faces (and adjacent cells) based on the face skewness, and then remesh them.

Local face remeshing also allows the remeshing of wedge cells in boundary layers at those boundaries. The detection of boundary layers (as well as the wedge element height distribution and number of layers) is automatic and does not require your input.

To apply local face remeshing, perform the following steps:

1. Enable the **Local Face** option in the **Remeshing** tab of the Mesh Method Settings Dialog Box (p. 5060), and set the **Maximum Face Skewness** to an appropriate global value.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. For each deforming or user-defined boundary zone on which you want local face remeshing applied, enable the **Local** option in the **Meshing Options** tab of the Dynamic Mesh Zones Dialog Box (p. 5086). You can also revise the **Maximum Skewness** in this tab if you don't want to use the global setting for a particular zone. Note that for deforming zones, the **Remeshing** option must be enabled—which is the default condition—in order to access the **Local** option, and the **Global Settings** option must be disabled to revise the **Maximum Skewness**. For further details on the zone setup, see Deforming Motion (p. 1878) and/or User-Defined Motion (p. 1881).

12.6.2.3.1.1.2.1. Applicability of the Local Face Remeshing Method

When you enable local face remeshing for a boundary, the faces can be remeshed only if the following conditions are met:

- The faces are triangular.
- The agglomerated faces do not span multiple zones or feature edges.

Note that you cannot use the local face remeshing method in conjunction with adaption. For more information on the available adaption methods, see Hanging Node Adaption and Polyhedral Unstructured Mesh Adaption in the Theory Guide.

12.6.2.3.1.1.3. Local Remeshing Based on Sizing Function

Instead of marking cells based on minimum and maximum length scales, Ansys Fluent also marks cells based on the size distribution generated by the sizing function if the **Sizing Function** option is enabled.

Cells can be marked using sizing functions only with the following remeshing methods:

- local cell remeshing
- 2.5D surface remeshing (as described in 2.5D Surface Remeshing Method (p. 1825))

Figure 12.38: Mesh at the End of a Dynamic Mesh Simulation With Sizing Functions (p. 1815) demonstrates the advantages of using sizing functions for local remeshing.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.37: Mesh at the End of a Dynamic Mesh Simulation Without Sizing Functions

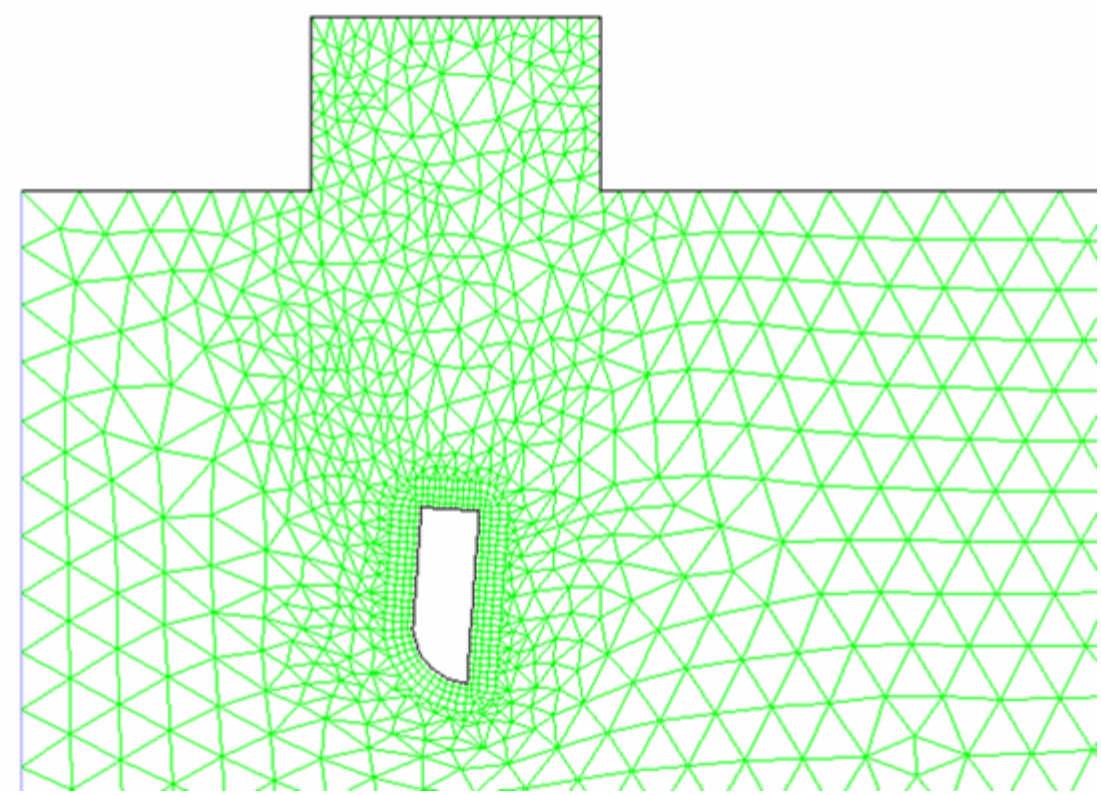


Figure 12.38: Mesh at the End of a Dynamic Mesh Simulation With Sizing Functions

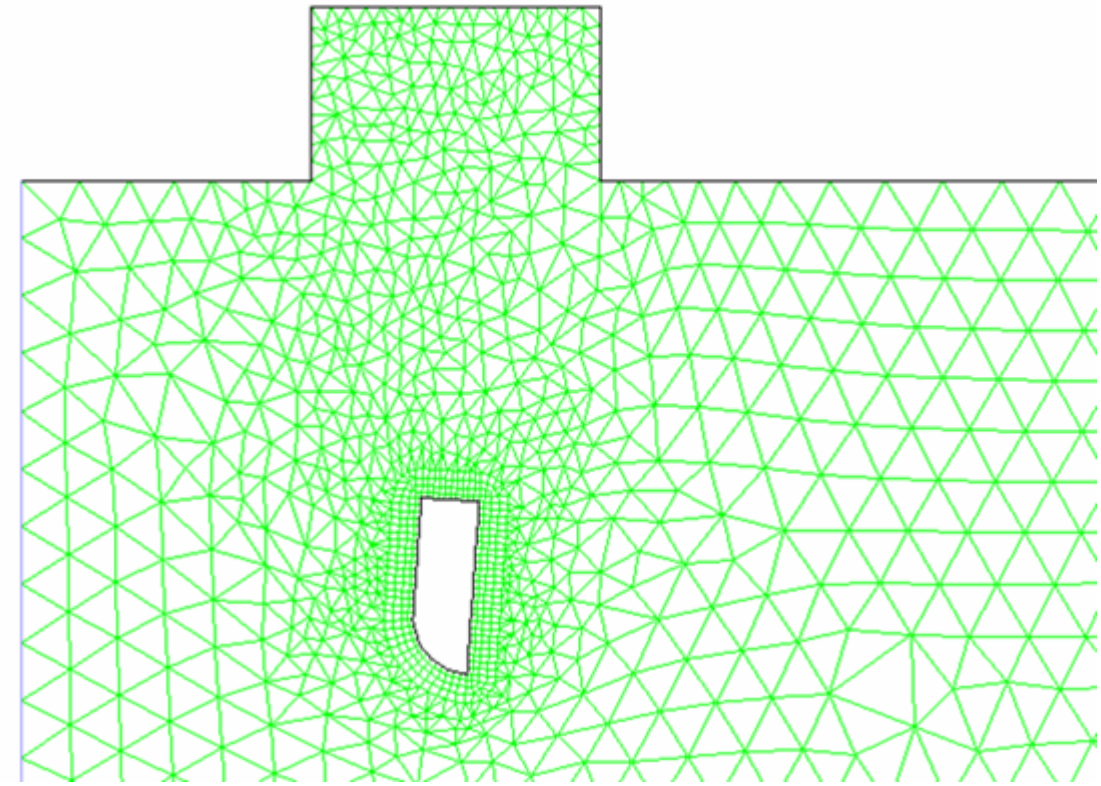
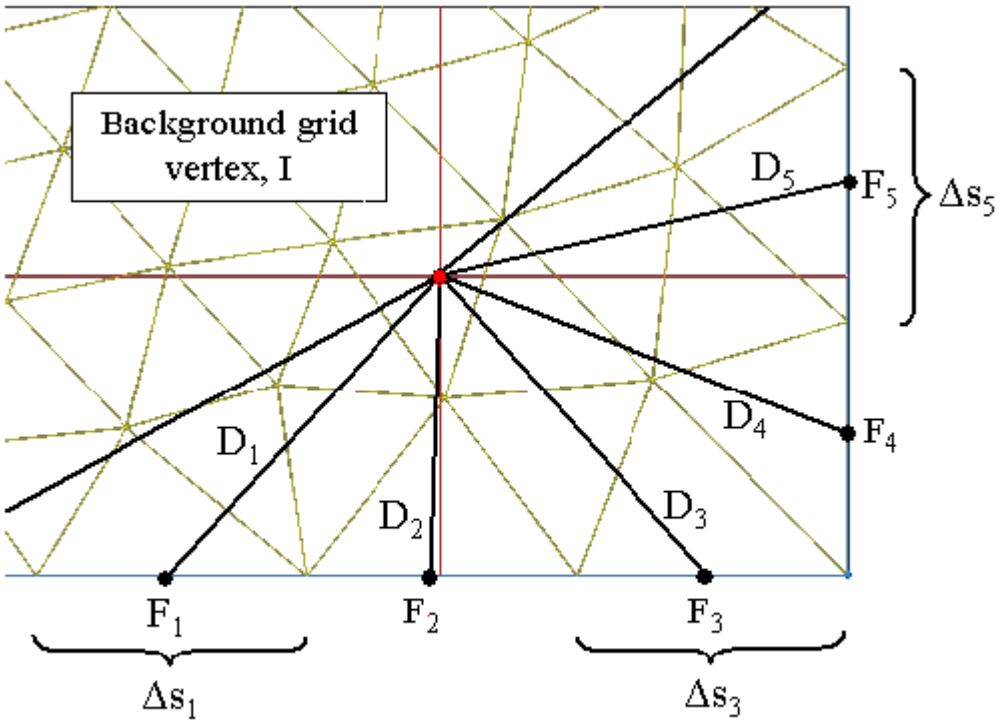


Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In determining the sizing function, Ansys Fluent draws a bounding box around the zone that is approximately twice the size of the zone, and locates the shortest feature length within each fluid zone. Ansys Fluent then subdivides the bounding box based on the shortest feature length and the sizing function **Resolution** that you specify. This allows Ansys Fluent to create a background mesh.

You control the resolution of the background mesh and a background mesh is created for each fluid zone. The shortest feature length is determined by shrinking a second box around the object, and then selecting the shortest edge on that box. The sizing function is evaluated at the vertex of each individual background mesh.

Figure 12.39: Sizing Function Determination at Background Mesh Vertex I



As seen in Figure 12.39: Sizing Function Determination at Background Mesh Vertex I (p. 1816), the local value of the sizing function SF_I is defined by

$$SF_I = \left(\frac{\Sigma \frac{1}{D_J} \Delta s_J}{\Sigma \frac{1}{D_J}} \right) \tag{12.17}$$

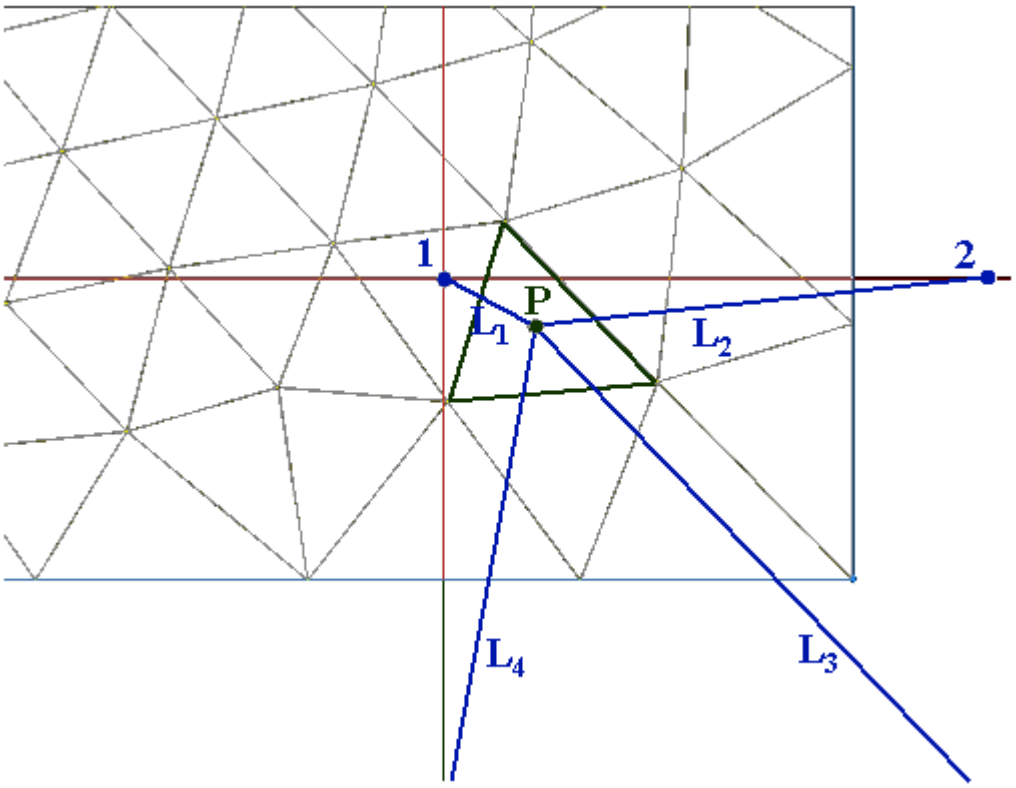
where D_J is the distance from vertex I on the background mesh to the centroid of boundary cell J and Δs_J is the mesh size (length) of boundary cell J.

The sizing function is then smoothed using Laplacian smoothing. Ansys Fluent then interpolates the value of the sizing function by calculating the distance L_I from a given cell centroid P to the background mesh vertices that surround the cell (see Figure 12.40: Interpolating the Value of the Sizing Function (p. 1817)). The intermediate value of the sizing function $size_b$ at the centroid is computed from

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$size_b = \left(\frac{\Sigma SF_I \frac{1}{L_I}}{\Sigma \frac{1}{L_I}} \right) \tag{12.18}$$

Figure 12.40: Interpolating the Value of the Sizing Function

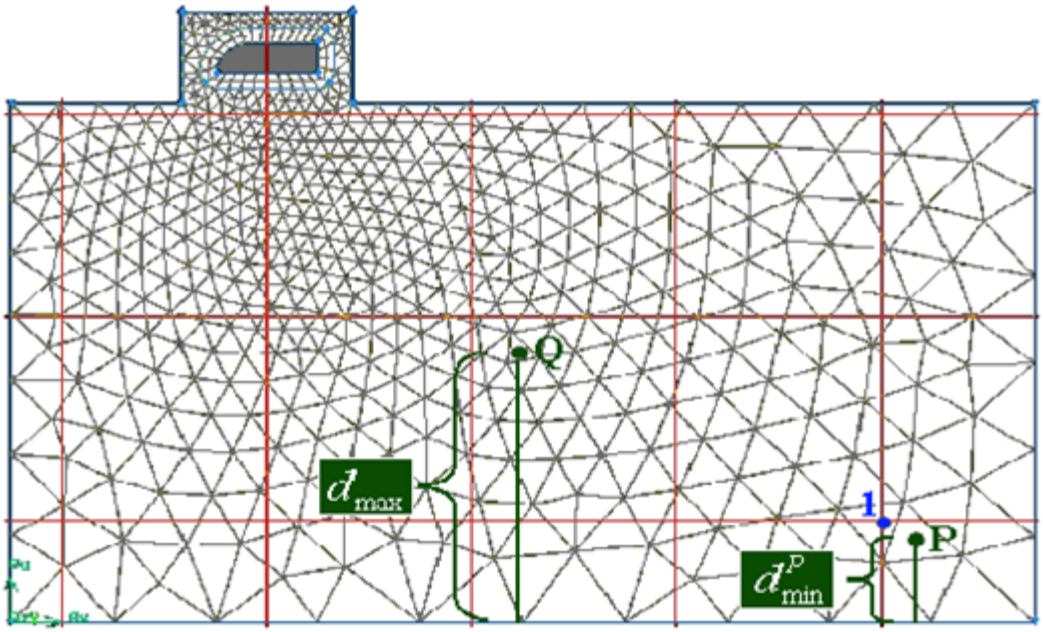


Next, a single point Q is located within the domain (see Figure 12.41: Determining the Normalized Distance (p. 1818)) that has the largest distance d_{max} to the nearest boundary to it. The normalized distance d_b for the given centroid P is given by

$$d_b = \frac{d^P_{min}}{d_{max}} \tag{12.19}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.41: Determining the Normalized Distance



Using the parameters α and β (the sizing function **Variation** and the sizing function **Rate**, respectively), you can write the final value $size_P$ of the sizing function at point P as

$$size_P = size_b \times \left(1 + \alpha \times d_b^{1+2\beta}\right) = size_b \times \gamma \tag{12.20}$$

where $size_b$ is the intermediate value of the sizing function at the cell centroid.

Note that α is the sizing function *variation*. Positive values mean that the cell size increases as you move away from the boundary. Since the maximum value of d_b is one, the maximum cell size becomes

$$size_{P,max} = size_b \times \left(1 + \alpha\right) = size_b \times \gamma_{max} \tag{12.21}$$

therefore, α is really a measure of the maximum cell size.

The factor γ is computed from

$$\gamma = 1 + \alpha d_b^{1+2\beta} \quad \text{if } \alpha > 0 \tag{12.22}$$

$$\gamma = 1 + \alpha d_b^{\frac{1}{1-\beta}} \quad \text{if } \alpha < 0 \tag{12.23}$$

You can use sizing function **Variation** (or α) to control how large or small an interior cell can be with respect to its closest boundary cell. α ranges from -1 to ∞, an α value of 0.5 indicates that the interior cell size can be, at most, 1.5 the size of the closest boundary cell. Conversely, an α value of -0.5 indicates that the cell size interior of the boundary can be half of that at the closest boundary cell. A value of 0 indicates a constant size distribution away from the boundary.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can use the sizing function **Rate** (or β) to control how rapidly the cell size varies from the boundary. The value of β should be specified such that $-0.99<\beta<+0.99$. A positive value indicates a slower transition from the boundary to the specified sizing function **Variation** value. Conversely, a negative value indicates a faster transition from the boundary to the sizing function **Variation** value. A value of 0 indicates a linear variation of cell size away from the boundary.

You can also control the **Resolution** of the sizing function. This determines the size of the background bins used to evaluate the size distribution with respect to the shortest feature length of the current mesh. By default, the sizing function **Resolution** is 3 in 2D problems, and 1 in 3D problems.

Note that if you edit the **Resolution**, **Variation**, and/or **Rate**, clicking **Default** will return these fields to the default values based on the current mesh. The **Default** button will then change to be a **Reset** button, which can be used to return to the prior values.

In summary, the sizing function is a distance-weighted average of all mesh sizes on all boundary faces (both stationary and moving boundaries). The sizing function is based on the sizes of the boundary cells, with the size computed from the cell volume by assuming a perfect (equilateral) triangle in 2D and a perfect tetrahedron in 3D. You can control the size distribution by specifying the sizing function **Variation** and the sizing function **Rate**. If you have enabled the **Sizing Function** option, Ansys Fluent will agglomerate a cell if

$$size \notin \left[\frac{4}{5}\gamma size_b, \frac{5}{4}\gamma size_b\right] \tag{12.24}$$

where γ is a factor defined by Equation 12.22 (p. 1818) and Equation 12.23 (p. 1818).

Note that the sizing function is only used for marking cells *before* remeshing. The sizing function is not used to govern the size of the cell during remeshing.

For steady-state applications (see Steady-State Dynamic Mesh Applications (p. 1892)), you can instruct Ansys Fluent to perform a second round of cell marking and agglomeration after the boundary has moved, based on skewness criteria. The intent is to further improve the mesh quality through additional local remeshing. This optional feature works in conjunction with the **Mesh Method Settings** dialog box (Figure 12.35: The Remeshing Tab in the Mesh Method Settings Dialog Box for Methods-Based Remeshing (p. 1811)), and operates according to the skewness parameters you set in this dialog box. The sizing function parameters are not considered during this additional remeshing. Note that enabling this option will increase the time required to update the mesh during the solution.

Note:

If you want to employ additional local remeshing, first make sure that you have enabled the **Remeshing** option in the Dynamic Mesh Task Page (p. 5057).

To enable the additional round of local remeshing, use the following text command:

`define → dynamic-mesh → controls → remeshing-parameter → remeshing-after-moving?`

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12.6.2.3.1.2. Cell Zone Remeshing Method

The cell zone remeshing method allows for the remeshing of the complete cell zone, and provides the option to also remesh the faces of all adjacent deforming dynamic face zones. This remeshing method is enabled by default when local cell remeshing is enabled, and is performed automatically if the local cell remeshing does not produce an acceptable mesh (see Local Remeshing Method (p. 1812) for the acceptability criteria). Cell zone remeshing can also be manually invoked, using the following text command:

`define` → `dynamic-mesh` → `actions` → `remesh-cell-zone`

The cell zone remeshing method is available for triangular cells in 2D meshes and tetrahedral cells in 3D meshes. For 3D meshes, the method also allows the remeshing of wedge cells in boundary layers. The detection of the boundary layers (as well as the wedge element height distribution and number of layers) is automatically performed by default, and allows for different layer parameters on each boundary zone. You can manually specify the parameters by entering nonzero values for first height, growth rate, and number of layers via the text commands available in the `define/dynamic-mesh/controls/remeshing-parameters/prism-layer-parameters` menu, although generally it is not necessary to do this. When you enter them manually, the boundary layer parameters are global: they apply to every prism layer detected in the remeshing zone.

Note that it is necessary to enable the dynamic mesh model and the remeshing method in order to attain access to the prism layer controls, even if the cell zone is remeshed manually and not as part of a dynamic mesh update.

12.6.2.3.1.2.1. Limitations of the Cell Zone Remeshing Method

Zone remeshing has the following limitations:

- Only triangular, tetrahedral, and wedge cell types (when the wedge cells are part of a 3D boundary layer mesh) are remeshed.
- Zones with hanging nodes cannot be remeshed.

12.6.2.3.1.3. Face Region Remeshing Method

The face region remeshing method allows for the remeshing of those triangular faces (in 3D meshes) and linear faces (in 2D meshes) that are on a deforming face zone and adjacent to a moving face zone (see layer j in Figure 12.42: Expanding Cylinder Before Region Face Remeshing (p. 1821)). Ansys Fluent marks the faces based on minimum and maximum length scales, and then remeshes the faces and the associated cells to produce a very regular mesh on the deforming boundary. Although primarily designed for in-cylinder type configurations, where the remeshing region is located where cylinder walls meet the moving piston, face region remeshing can be used for all applications where a moving dynamic zone abuts deforming dynamic face zones.

For 3D simulations, Ansys Fluent allows face region remeshing with symmetric boundary conditions and across multiple face zones. The remeshing can preserve features not only between the different deforming face zones, but also within a face zone. For more information on feature preservation, see Feature Detection (p. 1836). Ansys Fluent also allows face region remeshing of tetrahedral cell zones that contain wedge cells in boundary layers, as described in the section that follows.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To begin marking the faces for face region remeshing, Ansys Fluent identifies the nodes at the intersection of a moving dynamic zone and the adjacent deforming zones. Ansys Fluent then analyzes the height of the faces on the deforming zones that are in the range of the identified nodes, and then remeshes the faces depending on the specified maximum or minimum length scale.

Consider the simple tetrahedral mesh of a cylinder that has a moving end wall (see Figure 12.42: Expanding Cylinder Before Region Face Remeshing (p. 1821)). The faces that are subject to remeshing are in layer j of the side wall. If the faces in layer j are expanding, the expansion continues until the height h reaches the maximum length scale, and then the layer is remeshed to form 2 layers of elements (see Figure 12.43: Expanding Cylinder After Region Face Remeshing (p. 1822)). Conversely, if the faces of layer j are contracting, the contraction continues until h reaches the minimum length scale, and then layer j and the neighboring layer of faces (layer i) on the deforming zone are remeshed to form a single layer.

Figure 12.42: Expanding Cylinder Before Region Face Remeshing

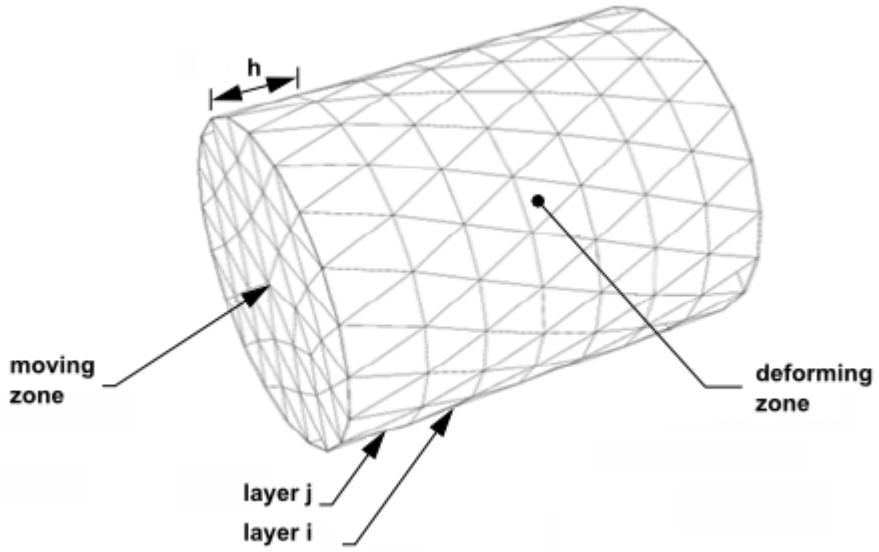


Figure 12.43: Expanding Cylinder After Region Face Remeshing

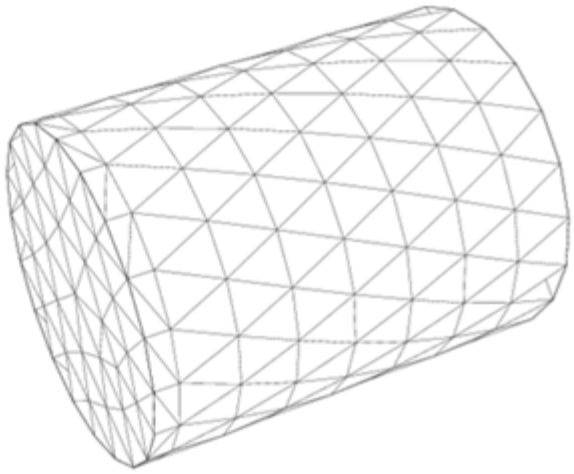


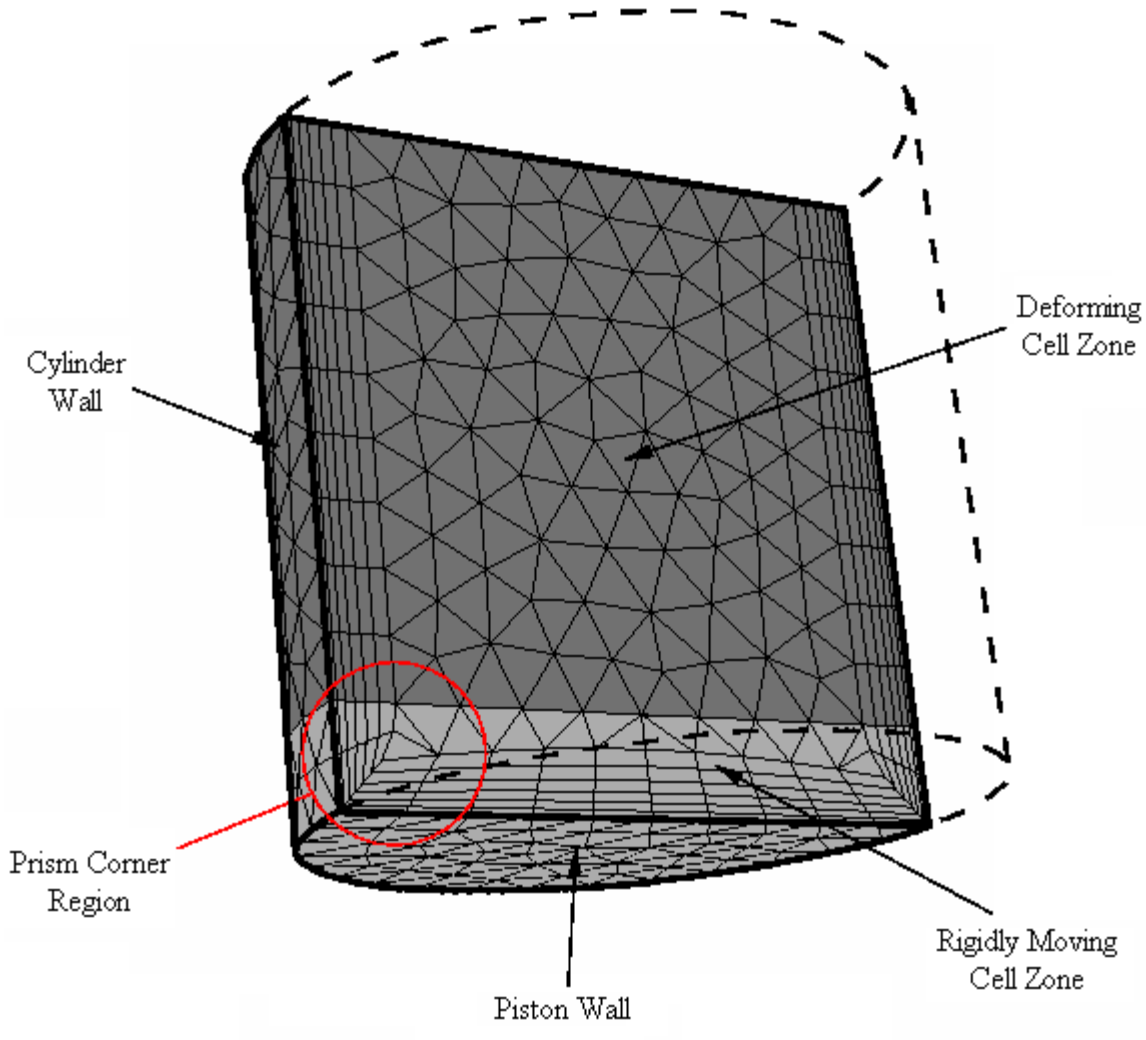
12.6.2.3.1.3.1. Face Region Remeshing with Wedge Cells in Prism Layers

In 3D simulations, the face region remeshing method can be applied on meshes that have wedge cells along the deforming face zones. When remeshing the faces on the deforming face zones, the associated wedge cells are remeshed as well. The layer parameters are based on the existing mesh by default; you have the option of manually setting these parameters, as described later in this section.

If the motion of the face zone is large compared to the height of the adjacent deforming face zones, it is recommended that you decompose the mesh volume in such a way as to create a dynamic cell zone that moves as a rigid body in between the moving face zone and the deforming dynamic cell zone on which face region remeshing is applied. Consider Figure 12.44: Volume Decomposition for Prism Layers (p. 1823), which displays only half of an in-cylinder mesh. The rigidly moving cell zone encapsulates the prism layers on the moving piston so that the layers are not remeshed, and therefore the risk of generating degenerate cells during the mesh motion update is reduced.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.44: Volume Decomposition for Prism Layers

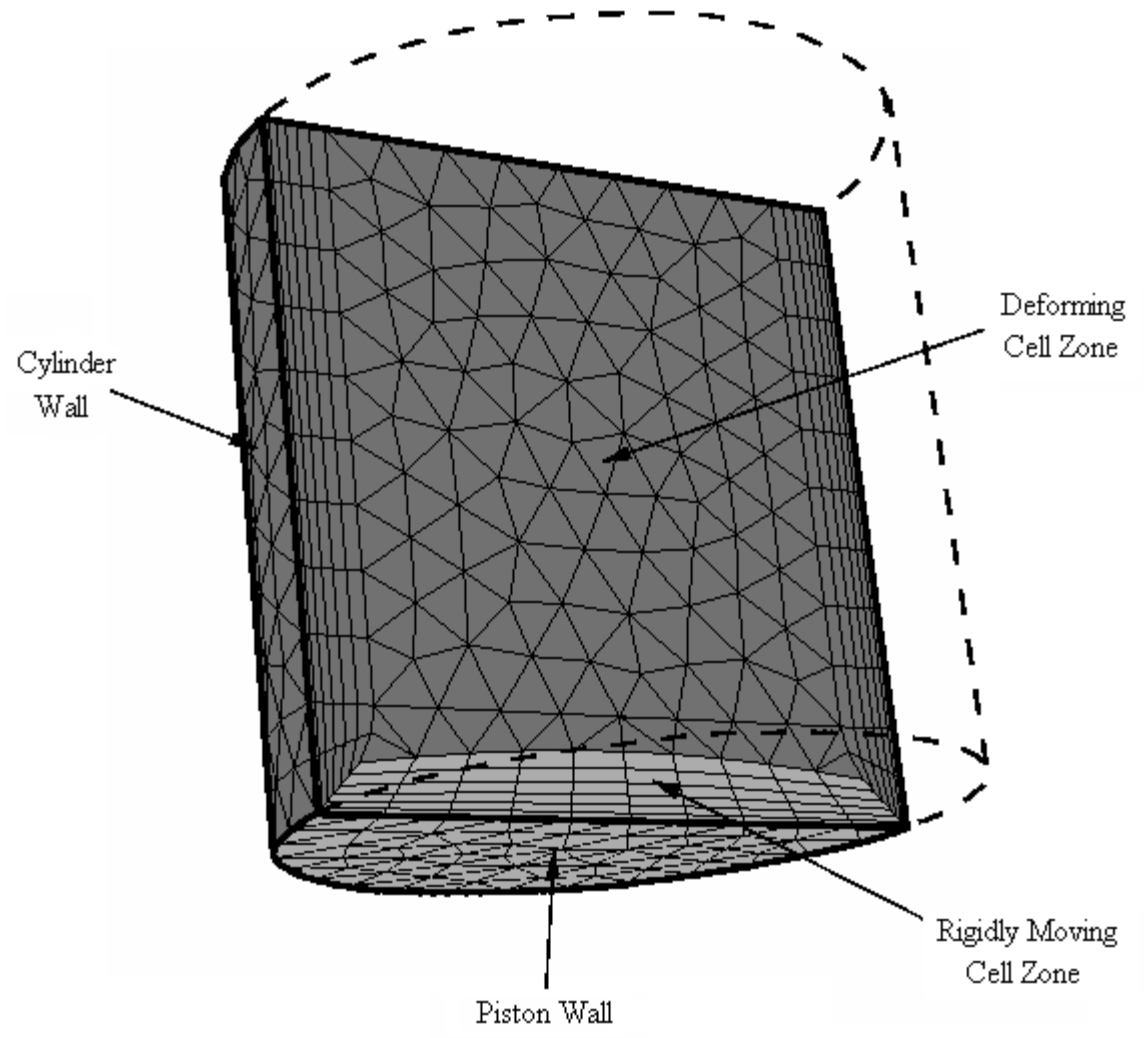


It is preferable (and even mandatory, if the mesh is a half model with a symmetry plane) to decompose the volume such that the "corner" region of the prism layers (shown in the previous figure) exists entirely within the rigidly moving zone. This allows for the largest deformations without risking degenerate elements, because the prism normals of the remeshed cells are uniformly perpendicular to the faces undergoing remeshing.

If the range of motion does not allow you to encapsulate the entire corner region of the prism layers in a rigidly moving zone, it is recommended that you encapsulate the "base" of the prism layers (shown in Figure 12.45: Volume Decomposition for the Base of the Prism Layers (p. 1824)) and move these cells with a rigid body motion. Although this is less ideal than encapsulating the corner region, it does reduce the risk of degenerate mesh elements.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.45: Volume Decomposition for the Base of the Prism Layers



For piston-type applications that contain prism layers, a reasonable rule of thumb is that you should decompose the mesh volume if the piston motion is more than half the cylinder height. If you decide not to decompose the volume at all, you must at the very least enable the **Deform Adjacent Boundary Layer with Zone** option in the **Meshing Options** tab of the **Dynamic Mesh Zone** dialog box when setting up the moving face zone (see Rigid Body Motion (p. 1874) for details). In any case, it is recommended that you always preview the mesh motion over the complete simulation time, to make sure that you will have a valid mesh at each time step.

The prism layer parameters (that is, element height, growth rate, and number of layers) are extracted automatically from the mesh and do not generally require your input. To prevent the prism parameters from drifting due to repeated remeshing, the prism parameters for first height, growth rate, and number of layers can be entered manually, using the text commands available in the `define/dynamic-mesh/controls/remeshing-parameters/prism-layer-parameters` menu.

12.6.2.3.1.3.2. Applicability of the Face Region Remeshing Method

Note the following limitations associated with face region remeshing:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- You can use the face region remeshing method only in cell zones that contain triangular cells (in 2D) or tetrahedral cells, with or without prism layers (in 3D). For 3D meshes, the faces on the deforming boundaries that border the moving face must all be triangular.
- The face region remeshing method is not compatible with diffusion-based smoothing or linearly elastic solid smoothing.
- You cannot use the face region remeshing method in conjunction with adaption. For more information on the available adaption methods, see Hanging Node Adaption and Polyhedral Unstructured Mesh Adaption in the Theory Guide.

12.6.2.3.1.4. 2.5D Surface Remeshing Method

The 2.5D surface remeshing method only applies to extruded 3D geometries and is similar to local remeshing in two dimensions on a triangular surface mesh (not a mixed zone). Faces on a deforming boundary are marked for remeshing based on face skewness, minimum and maximum length scale; the 2.5D remeshing method also gives you the option of marking cells using sizing functions, as described in Local Remeshing Based on Sizing Function (p. 1814).

Figure 12.46: Close-Up of 2.5D Extruded Flow Meter Pump Geometry Before Remeshing and Laplacian Smoothing

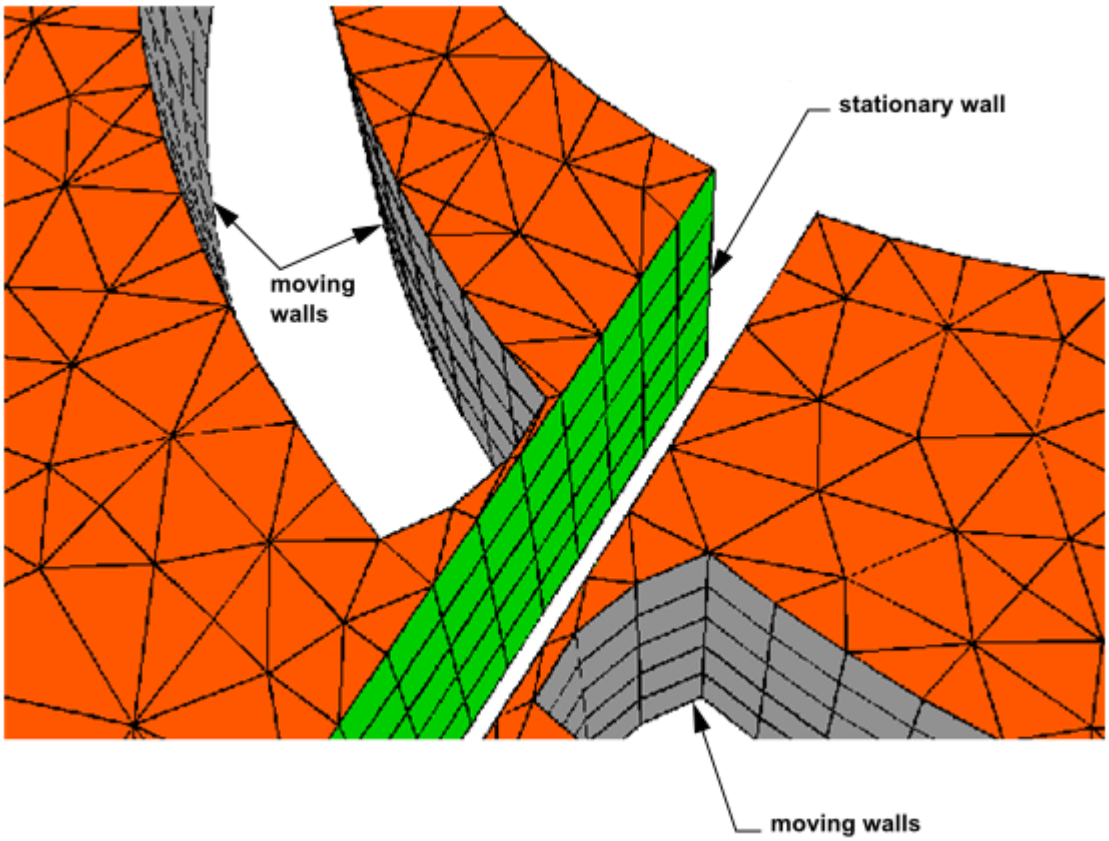


Figure 12.47: Close-Up of 2.5D Extruded Flow Meter Pump Geometry After Remeshing and Laplacian Smoothing

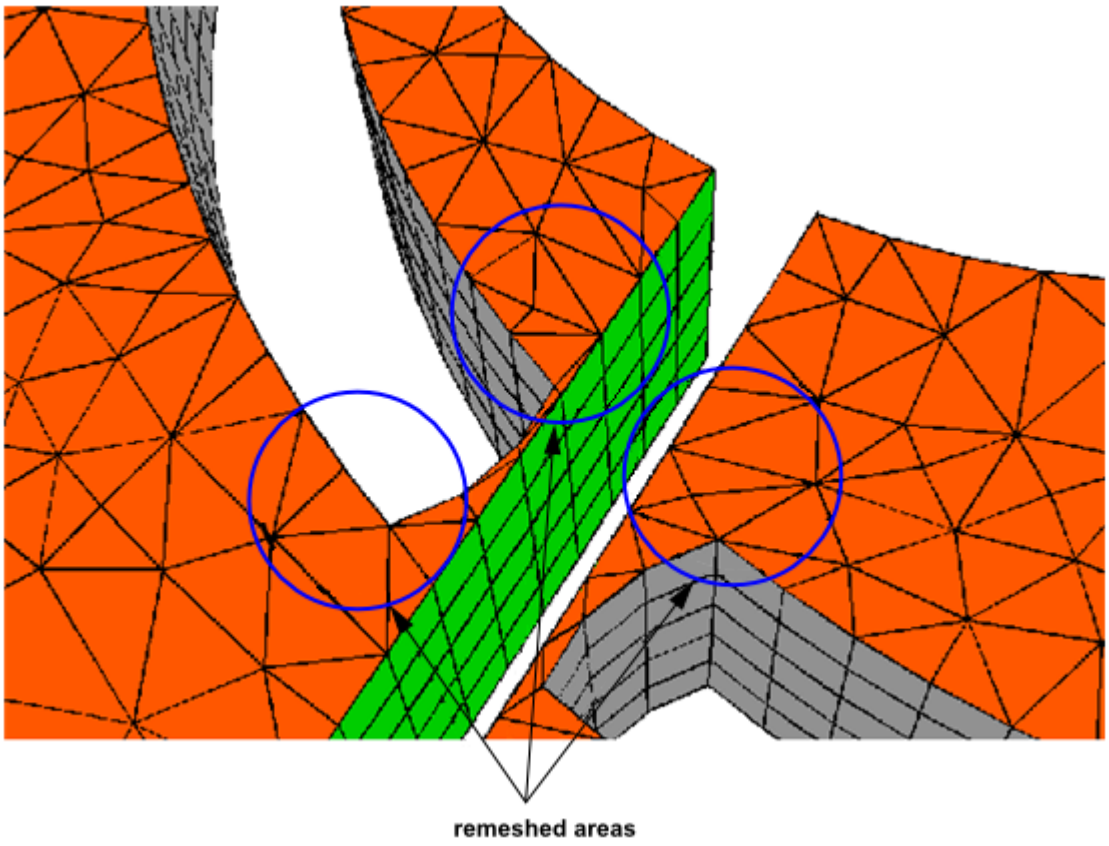


12.6.2.3.1.4.1. Applicability of the 2.5D Surface Remeshing Method

The following applies to the 2.5D surface remeshing method:

- Triangular faces get remeshed based on marking.
- Extruded wedges get remeshed based on the remeshing of the triangular face. Only extruded regions get remeshed, not mixed regions.
- The 2.5D remeshing method does not support remeshing or moving nodes on the perimeter of the extruded zone(s).
- The only smoothing method that is compatible with 2.5D remeshing is Laplacian smoothing.
- Note that you cannot use the 2.5D surface remeshing method in conjunction with adaption. For more information on the available adaption methods, see Hanging Node Adaption and Polyhedral Unstructured Mesh Adaption in the Theory Guide.
- The extrusion must be along a straight line normal to the deforming zone and the cross-section of the extruded/coopered mesh must be constant along the extrusion direction. For more information about the 2.5D model, see Using the 2.5D Model (p. 1827).
- Periodics are not supported at the extruded zones.

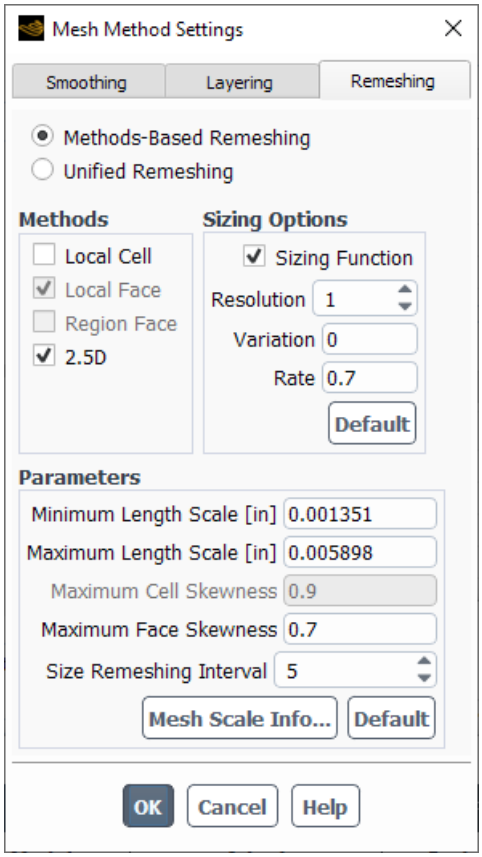
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12.6.2.3.1.4.2. Using the 2.5D Model

For 3D simulations only, you can select the **2.5D** model under the **Remeshing** tab in the Mesh Method Settings Dialog Box (p. 5060). This model allows for a specific subset of remeshing techniques.

The 2.5D mesh essentially is a 2D triangular mesh which is expanded, or extruded, along the normal axis of the specific dynamic zone that you are interested in modeling. The triangular surface mesh is remeshed and smoothed on one side, and the changes are then extruded to the opposite side. Rigid body motion is applied to the moving face zones, while the triangular extrusion surface is assigned to a deforming zone with remeshing and smoothing enabled. The opposite side of the triangular mesh is assigned to be a deforming zone as well, with only smoothing enabled, as in Figure 12.49: 2.5D Extruded Gear Pump Geometry (p. 1828).

Figure 12.48: The Remeshing Tab for the 2.5D Model

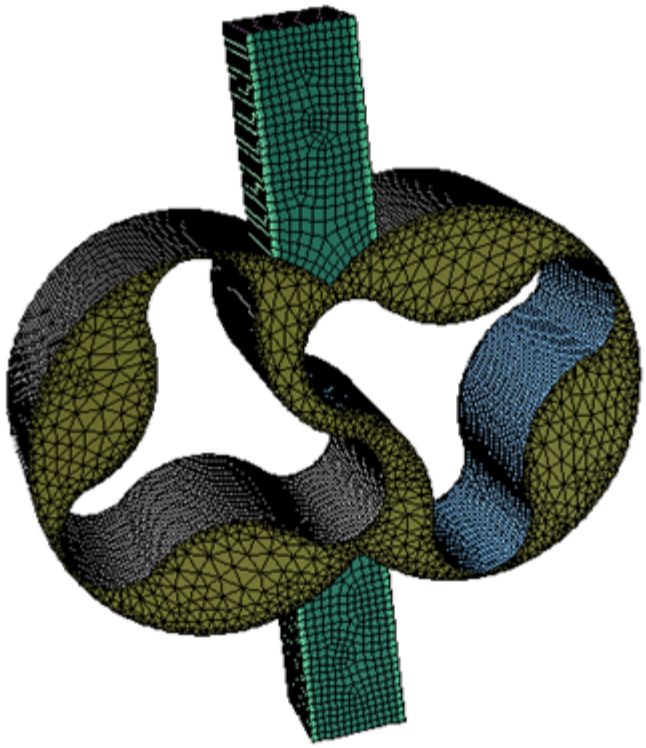


For more information on setting smoothing and remeshing parameters, see Dynamic Mesh Update Methods (p. 1784).

The 2.5D model only applies to mappable (that is, extrudable) mesh geometries such as pumps, as in Figure 12.49: 2.5D Extruded Gear Pump Geometry (p. 1828). Only the aspects of the geometry that represent the "moving parts" must be extruded in the mesh.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.49: 2.5D Extruded Gear Pump Geometry



Important:

You must only apply smoothing to the opposite side of the extruded mesh, since Ansys Fluent requires the geometry information for the dynamic zone. Ansys Fluent projects the nodes back to its geometry after the extrusion. Without this geometry information, the dynamic zones tends to lose its integrity.

Important:

In parallel, a partition method that partitions perpendicular to the extrusion surface should be used. For example, if the normal of the extrusion surface points in the X-direction then Cartesian-Y or Cartesian-Z would be the perfect partition methods.

The 2.5D model is used in combination with a `DEFINE_GRID_MOTION` UDF. (See Hooking `DEFINE_GRID_MOTION` UDFs in the Fluent Customization Manual for information about hooking this UDF.)

This UDF is associated with the extrusion surface that is adjacent to the cell zone, in turn applying the same deformation to the entire cell zone. This approach is particularly useful when modeling gear pumps that are predominantly extruded hexahedral meshes. For more information about this UDF, contact your support engineer.

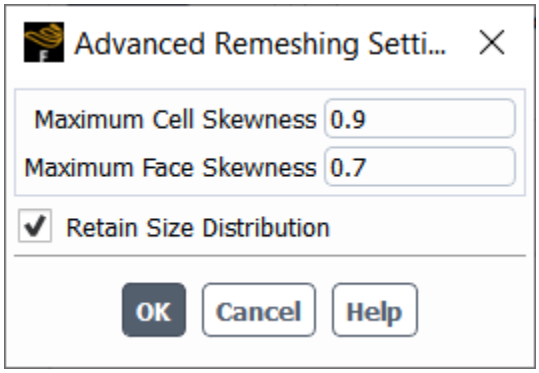
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12.6.2.3.2. Unified Remeshing

When **Unified Remeshing** is selected in the **Remeshing** tab of the **Mesh Method Settings** dialog box, the mesh quality is improved using an algorithm that combines aspects of a variety of remeshing methods and by default attempts to maintain the initial mesh size distribution even as the mesh moves. **Unified Remeshing** simplifies the remeshing setup and can provide increased robustness compared to other methods, especially for parallel simulations.

If the default settings of the **Unified Remeshing** method do not yield a desirable mesh distribution for your simulation, you can attempt to improve it by clicking the **Advanced...** button and using the **Advanced Remeshing Settings** dialog box that opens. The value of the **Maximum Cell Skewness** sets the threshold for remeshing cells based on skewness, and by default is set to 0.9 for 3D simulations and 0.7 for 2D simulations. For 3D cases, faces (and adjacent cells) on the boundaries of deforming or user-defined zone types are remeshed based on the **Maximum Face Skewness**.

Figure 12.50: The Advanced Remeshing Settings Dialog Box



If necessary, you can disable the **Retain Size Distribution** option, so that algorithm does not attempt to respect the initial mesh distribution by using local size criteria, but instead marks cells for remeshing when their length scales are outside of the minimum and maximum length scale values of the cell zone in the initial mesh. Should these zonal values be unsuccessful, you can use the following text commands to specify other appropriate length scale values:

`define` → `dynamic-mesh` → `controls` → `remeshing-parameters` → `length-min`

and

`define` → `dynamic-mesh` → `controls` → `remeshing-parameters` → `length-max`

The mesh is evaluated at every time step, and the remeshing is applied only if the quality of the cells / faces has improved.

Note:

- Unified remeshing is applied to triangular or tetrahedral cells, and can produce wedge cells in 3D boundary layer meshes.
- You cannot use unified remeshing in conjunction with adaption. For more information on the available adaption methods, see Hanging Node Adaption and Polyhedral Unstructured Mesh Adaption in the Theory Guide.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You have the option of creating additional controls that can affect the size distribution of the cells throughout the mesh or just the wedge cells in boundary layers by using the `define/dynamic-mesh/controls/remeshing-parameters/sizing-controls` or `define/dynamic-mesh/controls/remeshing-parameters/prism-controls/` text command menus, respectively. It is generally not necessary to create such controls, but they may be helpful if you have strict sizing requirements or want more information when troubleshooting size-related issues. Note that any sizing controls and/or prism controls created in the meshing mode as part a **Watertight Geometry** meshing guided workflow (as described in Using the Watertight Geometry Meshing Guided Workflows (p. 291)) are automatically imported and used as part the **Unified Remeshing**. For further details, see the following sections:

12.6.2.3.2.1. Sizing Controls

12.6.2.3.2.2. Prism Controls

12.6.2.3.2.1. Sizing Controls

When the **Retain Size Distribution** option is enabled in the **Advanced Remeshing Settings** dialog box, you can use one or more sizing controls to modify the algorithm that attempts to respect the initial mesh distribution during unified remeshing. Each sizing control definition is applied to one or more boundary zones, and then affects the size of the cells throughout the mesh based on their distance from those boundary zone(s) and your settings in the definition. Any sizing controls created in the meshing mode as part a **Watertight Geometry** meshing guided workflow (as described in Using the Watertight Geometry Meshing Guided Workflows (p. 291)) are automatically imported and used; you can choose to edit and/or delete these, and/or create new controls.

> **Warning:**
>
> Sizing controls should be used with caution by experienced users only, as they could make your simulation less robust if used incorrectly.

To create and manage sizing controls, perform the following steps:

1. Define a sizing controls definition using the following text command:

   `define` → `dynamic-mesh` → `controls` → `remeshing-parameters` → `sizing-controls` → `add`

   After being prompted for a name, you can enter the following to complete the definition:

   - `zones`

     This specifies all of the boundary zones on which the sizing controls definition is applied.

   - `growth-rate`

     This sets the growth rate of the sizing controls definition.

   - `motion`

     This determines whether the evaluation of the sizing of the cells that result from the sizing control definition is updated when zones move: `auto` specifies that Fluent updates

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the evaluation during motion; and `static` specifies that the evaluation is not updated during motion.

- `type`

  This specifies how the sizing is affected by the selected boundary zones: `auto` specifies that the default size distribution (rather than the initial size distribution in your selected boundary zones) is used, along with your specified `max-length` and `min-length` values; `soft` specifies that the maximum length scale of your selected boundary zones is used, along with your specified `min-length` value; and `meshed` specifies that the maximum and minimum length scales of your selected boundary zones are used, in order to respect their initial size distribution. This setting is only relevant if you have more than one sizing controls definition.

- `max-length`

  This sets a maximum length threshold that is used when the `type` is set to `auto` or `soft`.

- `min-length`

  This sets a minimum length threshold that is used when the `type` is set to `auto`.

- `interval`

  This sets the interval (in time steps) at which the evaluation of the sizing of the cells that result from the sizing control definition is updated. This setting is only relevant when `auto` is selected for the `motion` setting. By default, the `interval` is set to `10` time steps. This setting does not typically need to be adjusted: you could decrease it if you are using large time steps (which is not recommended), and you could increase it if it negatively impacts the calculation speed.

- `name`

  You can use this to revise the name you entered when you created the sizing controls definition.

When the definition is complete, enter `q` to return to the text command menu.

2. You can repeat the previous step if you would like additional sizing controls definitions.

3. You can perform the following actions as needed prior to running the calculation:

   - To edit an existing sizing controls definition, use the following text command:

     `define` → `dynamic-mesh` → `controls` → `remeshing-parameters` → `sizing-controls` → `edit`

   - To delete an existing sizing controls definition, use the following text command:

     `define` → `dynamic-mesh` → `controls` → `remeshing-parameters` → `sizing-controls` → `delete`

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- To print a list of the existing sizing controls definitions in the console, use the following text command:

  `define` → `dynamic-mesh` → `controls` → `remeshing-parameters` → `sizing-controls` → `list`

- To print the properties of an existing sizing controls definition in the console, use the following text command:

  `define` → `dynamic-mesh` → `controls` → `remeshing-parameters` → `sizing-controls` → `list-properties`

12.6.2.3.2.2. Prism Controls

When the **Retain Size Distribution** option is enabled in the **Advanced Remeshing Settings** dialog box, you can use one or more prism controls to modify the algorithm that attempts to respect the initial mesh distribution during unified remeshing. Each prism control definition is applied to one or more boundary zones, and then affects the height distribution and number of layers of the wedge cells in the adjacent boundary layers. Any prism controls created in the meshing mode as part a **Watertight Geometry** meshing guided workflow (as described in Using the Watertight Geometry Meshing Guided Workflows (p. 291)) are automatically imported and used; you can choose to edit and/or delete these, and/or create new controls.

> **Warning:**
>
> Prism controls should be used with caution by experienced users only, as they could make your simulation less robust if used incorrectly.

To create and manage prism controls, perform the following steps:

1. Define a prism controls definition using the following text command:

   `define` → `dynamic-mesh` → `controls` → `remeshing-parameters` → `prism-controls` → `add`

   After being prompted for a name, you can enter the following to complete the definition:

   - `zones`

     This specifies all of the boundary zones on which this prism controls definition is applied.

   - `nlayers`

     This sets the number of layers of wedge cells in the boundary layer adjacent to the specified `zones`.

   - `growth-method`

     This specifies the method used to determine the increase in height of the wedge cell layers beyond the first layer. The only available option is `geometric`, so that the height of each layer is the height of the previous layer multiplied by the `rate`.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- `rate`

  This sets the coefficient for the `growth-method` used to determine the increase in height of the wedge cell layers beyond the first layer.

- `offset-type`

  This allows you to select from the following types, in order to determine how the first layer of wedge cells (adjacent to the `zones`) are generated during remeshing:

  – `uniform`

    This specifies that every new node (child) of the first layer of wedge cells is the same distance away from its parent node (that is, the corresponding node on the boundary zone, from which the direction vector is pointing). This distance is defined by the `first-height`. The `uniform` type is selected by default.

  – `aspect-ratio`

    This specifies that the first layer of wedge cells that are extruded from the `zones` are defined using an aspect ratio, that is, the ratio of the local wedge base length (as averaged at the nodes) to the local wedge layer height. This aspect ratio is defined by the `first-aspect-ratio`. Note that for a uniform mesh, the heights of the cells in the first layer will be roughly the same, while for a varying mesh, these heights will vary.

  – `smooth-transition`

    This specifies that the last layer of wedge cells that are extruded from the `zones` are defined using a transition rate, that is, the ratio of the local wedge cell height (as averaged at the nodes) to the height of the local tetrahedral cell that will be generated adjacent to the last layer. This transition rate / ratio is defined by the `transition-rate`. This offset type allows you to easily provide a smooth transition for the cell volumes from the wedge cell layers to the cells deeper within the mesh. After the height of the last wedge cell layer is calculated, the height of the first layer is automatically computed according to your specified growth `rate` and `nlayers`. Note that for a uniform mesh, the heights of the cells in the first layer will be roughly the same, while for a varying mesh, these heights will vary.

  These offset types are similar to the offset method types available when adding boundary layers in a **Watertight Geometry** guided workflow in the meshing mode (as described in Adding Boundary Layers (p. 329)). For further details about how the `uniform` and `aspect-ratio` types affect the placement of the nodes during remeshing, see Offset Distances (p. 743).

- `first-height`

  This sets the height of the first layer of wedge cells in the boundary layer adjacent to the specified `zones`. It is used when `uniform` is selected for the `offset-type` (which is the default).

- `first-aspect-ratio`

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This sets the aspect ratio for the individual wedge cells in the first layer of cells adjacent to the specified `zones`. It is defined as the ratio of the local wedge base length (as averaged at the nodes) to the local wedge layer height. It is used when `aspect-ratio` is selected for the `offset-type`.

- `transition-rate`

  This sets the ratio of the local wedge cell height (as averaged at the nodes) in the last wedge cell layer to the height of the local tetrahedral cell that will be generated adjacent to the last layer (deeper within the mesh). It is used when `smooth-transition` is selected for the `offset-type`.

- `name`

  You can use this to revise the name you entered when you created the prism controls definition.

When the definition is complete, enter `q` to return to the text command menu.

2. You can repeat the previous step if you would like additional prism controls definitions.

3. You can perform the following actions as needed prior to running the calculation:

   - To edit an existing prism controls definition, use the following text command:

     `define` → `dynamic-mesh` → `controls` → `remeshing-parameters` → `prism-controls` → `edit`

   - To delete an existing prism controls definition, use the following text command:

     `define` → `dynamic-mesh` → `controls` → `remeshing-parameters` → `prism-controls` → `delete`

   - To print a list of the existing prism controls definitions in the console, use the following text command:

     `define` → `dynamic-mesh` → `controls` → `remeshing-parameters` → `prism-controls` → `list`

   - To print the properties of an existing prism controls definition in the console, use the following text command:

     `define` → `dynamic-mesh` → `controls` → `remeshing-parameters` → `prism-controls` → `list-properties`

12.6.2.4. Volume Mesh Update Procedure

The volume mesh is updated automatically based on the methods described in Dynamic Mesh Update Methods (p. 1784). Ansys Fluent decides which method to use for a particular zone based on which model is enabled and the shape of the cells in the zone. For example, if the boundaries of a tetrahedral cell zone are moving, the mesh smoothing and local remeshing methods will be used to update the volume mesh in this zone. If the zone consists of prismatic (hexahedral and/or wedge)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

cells, then the dynamic layer method will be used to determine where and when to insert and remove cell layers. On extruded prism zones, the 2.5D surface meshing method will be used.

Depending on which model is enabled, Ansys Fluent automatically determines which method to use by visiting the adjacent cell zones and setting appropriate flags for the volume mesh update methods to be used. If you specify the motion for a cell zone, Ansys Fluent will visit all of the neighboring cell zones and set the flags appropriately. If you specify the motion of a boundary zone, Ansys Fluent will analyze only the adjacent cell zones. If a cell zone does not have any moving boundaries, then no volume mesh update method will be applied to the zone.

Important:

Note that as a result of the remeshing procedures, updated meshes may be slightly different when dynamic meshes are used in parallel Ansys Fluent, and therefore very small differences may arise in the solutions.

Important:

Note that if your dynamic mesh model consists of numerous shell conduction zones, the mesh update may be very time consuming because all shells are deleted and recreated during the mesh update.

12.6.2.5. Transient Considerations for Remeshing and Layering

The second order in time transient formulation can be used with remeshing, layering, and smoothing cases. In such cases, second order in time accuracy is preserved during layering events and/or mesh smoothing. However, during remeshing events, the time advancement accuracy reverts to first order. Therefore, it is recommended that you only use second order in time for cases with very low remeshing frequency, that is, for cases where remeshing occurs every several time steps or more. If remeshing occurs every time step, the method reduces to a first order formulation. For cases that need very frequent remeshing, it is recommended that you retain the first order in time formulation. For details, see Dynamic Mesh Theory in the *Fluent Theory Guide*.

The switch to first order happens automatically when the solver detects a topology change as a result of remeshing within a time step. You will not see a change in the user interface, however you can monitor the switch between first and second order in time by using the following text command to enable the verbosity with dynamic meshes:

`define` → `dynamic-mesh` → `transient-settings` → `verbosity`

A message showing the active time formulation will print to the console when verbosity is set to `1`.

Note:

For cases with second order in time with dynamic mesh enabled, any mesh swapping and manual mesh manipulation will trigger a switch to first order in time.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

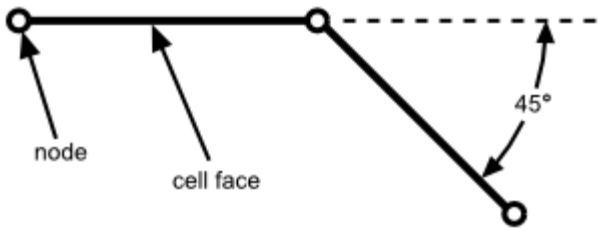
12.6.3. Feature Detection

The remeshing and/or smoothing of boundary zones may result in the chamfering of corners where cell faces meet. However, there may be some corners (identified by a particular angular range) that are important for your flow, and that you do not want chamfered. For 3D cases, you can specify that Ansys Fluent detects such corners (or "features") and preserves them. Such features may be at the juncture of different boundary zones, or they may be on a single non-planar boundary zone.

In the **Geometry Definition** tab of the Dynamic Mesh Zones Dialog Box (p. 5086) for any **Definition** type, you can indicate whether you want to preserve features by enabling **Feature Detection** under **Feature Options** and specifying a threshold value for the **Feature Angle**. A value of 180 degrees (the default) for the **Feature Angle** means that none of the corners must be preserved, whereas a value of 0 means that all of the corners must be preserved.

To illustrate the setting of the **Feature Angle**, see Figure 12.51: Cross Section of a 3D Corner (p. 1836). If you set the **Feature Angle** to 40 degrees, this corner would be guaranteed to be preserved. If you set it to 50 degrees, this corner could be chamfered.

Figure 12.51: Cross Section of a 3D Corner



12.6.3.1. Applicability of Feature Detection

The following items are applicable for use with feature detection:

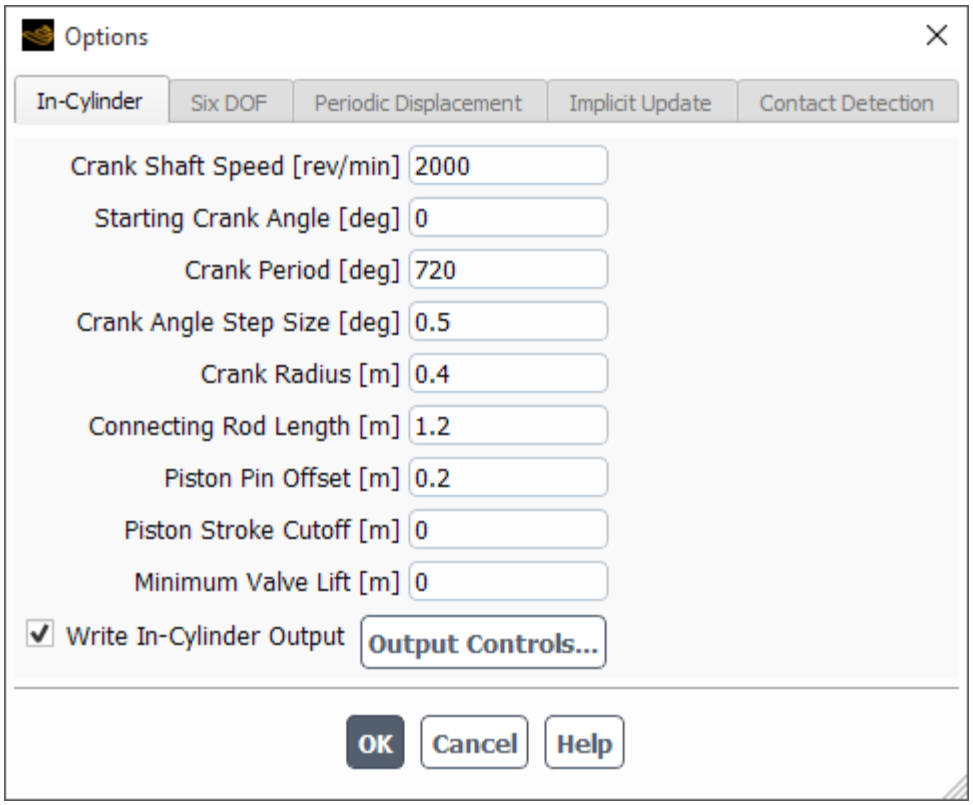
- Feature remeshing is only possible with face region remeshing.
- Features are preserved by local face remeshing, that is, there is no local face remeshing across features.
- Smoothing methods preserve features, that is, nodes at feature edges are not allowed to be smoothed.

12.6.4. In-Cylinder Settings

You can enable the **In-Cylinder** option in the Dynamic Mesh Task Page (p. 5057) (Figure 12.13: The Dynamic Mesh Task Page (p. 1783)) for transient problems. Then click the **Settings...** button in the **Options** group box to open the Options Dialog Box (p. 5067). Click the **In-Cylinder** tab and specify the **Crank Shaft Speed**, the **Starting Crank Angle**, and the **Crank Period**, which are used to convert between flow time and crank angle. You must also specify the time step size to use for advancing the solution in terms of crank angle in **Crank Angle Step Size**. By default, Ansys Fluent assumes a **Crank Angle Step Size** of 0.5 degrees.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

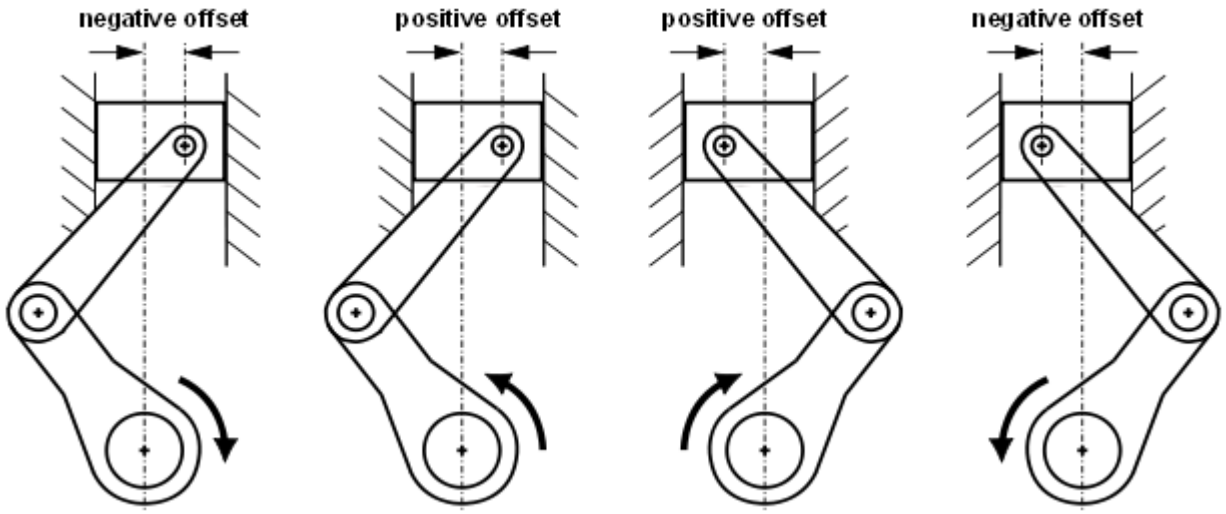
Figure 12.52: The In-Cylinder Tab of the Options Dialog Box



Ansys Fluent provides a built-in function that can define the location of the piston as a function of crank angle. This function is named ****piston-full****, and is selected from the **Motion UDF/Profile** drop-down list in the **Dynamic Mesh Zones** dialog box as part of rigid body motion (see Rigid Body Motion (p. 1874) for details). If you plan to specify the piston motion using this function, you must specify the **Crank Radius** (that is, the distance between the crank center and the center of the crank pin) and the **Connecting Rod Length**. You also have the option of entering a value for the **Piston Pin Offset** for cases when the piston pin is offset perpendicularly from the plane defined by the crank shaft axis and the direction of motion of the piston. The sign of this offset can be positive or negative, and is determined based on the geometry and the direction of rotation of the crank shaft (as shown in Figure 12.53: Determining the Sign of the Piston Pin Offset (p. 1838)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.53: Determining the Sign of the Piston Pin Offset



When the ****piston-full**** function is used, the piston location is calculated according to the following equation:

$$p_s=\sqrt{(r_c+L)^2-x_{\text{offset}}^2}-r_c\cos(\theta_c)-\sqrt{L^2-(r_c\sin(\theta_c)+x_{\text{offset}})^2} \tag{12.25}$$

where p_s is the piston location, r_c the crank radius, L is the connecting rod length, x_{offset} is the piston pin offset, and θ_c is the current crank angle.

The piston location p_s is always 0 at top-dead-center (TDC), that is, when the crank pin is perfectly aligned between the piston pin and the center of rotation of the crank shaft. TDC occurs when the crank angle is 0° when there is no piston pin offset, and prior to the crank angle reaching 0° when there is a positive piston pin offset. The piston location is a positive value at bottom-dead-center (BDC), that is, when the crank shaft is perfectly aligned between the piston pin and the crank pin. The value of p_s at BDC is equal to $2r_c$ when there is no piston pin offset, and greater than $2r_c$ when there is a nonzero piston pin offset (positive or negative).

The current crank angle θ_c is calculated from

$$\theta_c=\theta_s+t\Omega_{\text{shaft}} \tag{12.26}$$

where θ_s is the **Starting Crank Angle** and Ω_{shaft} is the **Crank Shaft Speed**.

The **Piston Stroke Cutoff** and **Minimum Valve Lift** values are used to control the actual values of the valve lift and piston stroke such that

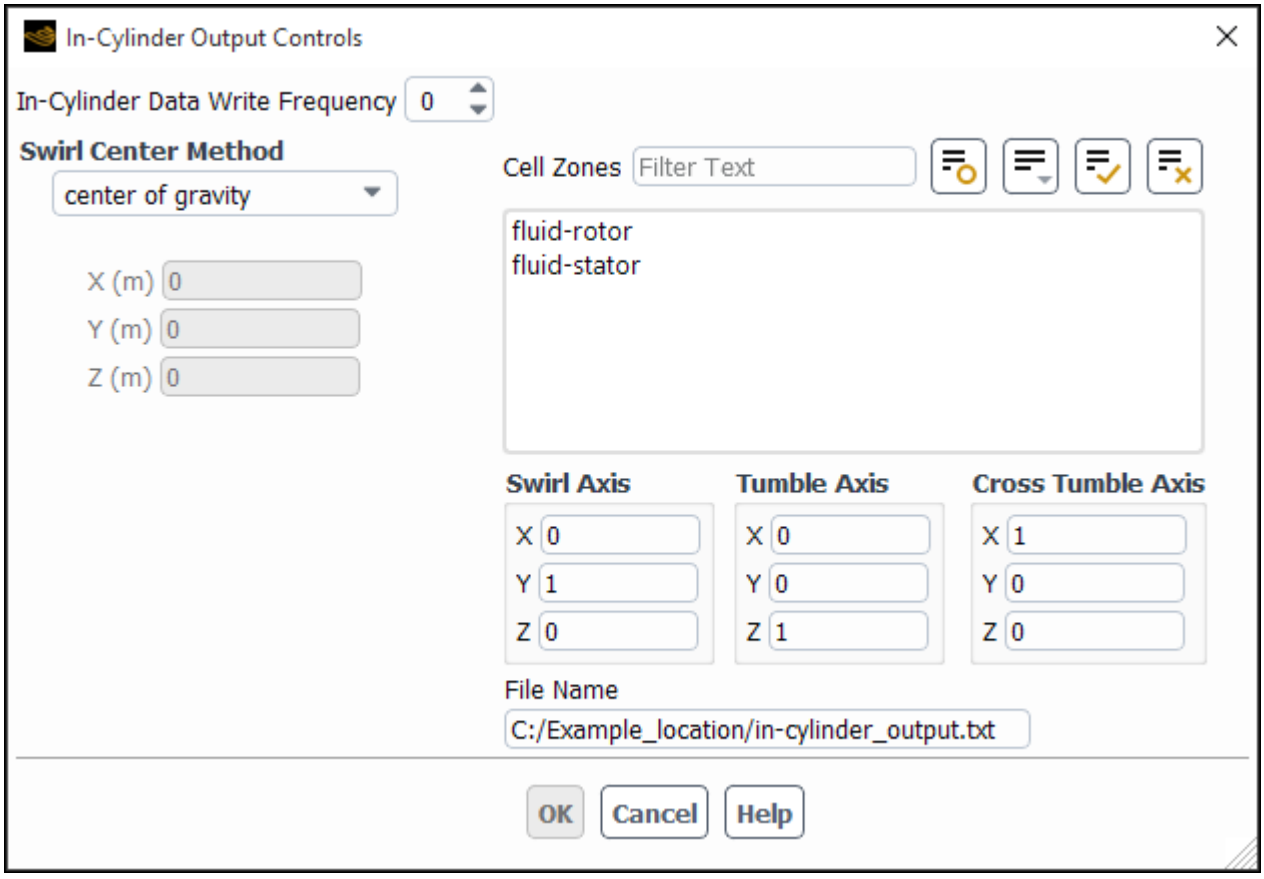
$$\begin{aligned} v_{lift}&=\max\left(v_{lift}^c, v_{lift}^{min}\right)\\ p_s&=\min\left(p_s^c, p_s^{min}\right)\end{aligned} \tag{12.27}$$

where v_{lift}^c is the valve lift computed from the appropriate valve profiles, v_{lift}^{min} is the **Minimum Valve Lift**, p_s^c is the stroke calculated from Equation 12.25 (p. 1838), and p_s^{min} is the **Piston Stroke Cutoff**. (See Defining Motion/Geometry Attributes of Mesh Zones (p. 1845) on how the **Piston Stroke Cutoff** is used to control the onset of layering in the cylinder chamber.)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Enable the **Write In-Cylinder Output** option then click the **Output Controls...** button if you want to specify specific output parameters. The In-Cylinder Output Controls Dialog Box (p. 5071) will open, where you can specify various quantities needed for the calculation of swirl and tumble along with the frequency of writing the output to the chosen file. Swirl is used to describe circulation about the cylinder axis. Tumble flow circulates around an axis perpendicular to the cylinder axis, orthogonal to swirl flow.

Figure 12.54: The In-Cylinder Output Controls Dialog Box



The following list describes the In-Cylinder Output Controls Dialog Box (p. 5071).

In-Cylinder Data Write Frequency

is an integer entry specifying the interval in number of time-steps. Make sure that a value other than 0 is used for the frequency, in order to allow you to complete your setup.

Swirl Center Method

is a drop-down list that allows you to select the method to calculate the swirl center. The list contains **center of gravity** and **fixed**, with **center of gravity** being the default value.

center of gravity

option calculates the swirl center inside the code and is used as the center of gravity of the chosen cell zones.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

fixed

option enables you to specify a swirl center in the entries below the drop-down list.

In addition to these two options, you can chose to use your own compiled UDF to calculate the swirl center.

For details on using a dynamic mesh UDF, see the Fluent Customization Manual for information on user-defined functions.

Cell Zones

is a list that displays the names of all existing cell zones in the case files. You can select only the zones relevant for the swirl and tumble calculations.

Swirl Axis

specifies the swirl axis with three entries for the directional components. By default, **X**, **Y**, **Z** = **0**, **1**, **0**.

Tumble Axis

specifies the directional components of **Tumble Axis** in **X**, **Y**, **Z** directions. By default, **X**, **Y**, **Z** = **0**, **0**, **1**. This applies only in 3D.

Cross Tumble Axis

specifies the directional components of **Cross Tumble Axis** in **X**, **Y**, **Z** directions. By default, **X**, **Y**, **Z** = **1**, **0**, **0**. This applies only in 3D.

File Name

specifies the name of the **In-Cylinder** output file. By default, the file name contains the name of the case file appended with a `.txt` extension.

The **In-Cylinder** specific output controls can also be controlled using the TUI as follows:

```
 Go to
 define/dynamic-mesh/controls/in-cylinder-output?
Enable in-cylinder output?[no] yes
Output Write Frequency[0] 10
Cell zone name/id(1)[()] 2
Cell zone name/id(1)[()]
File Name[''/nfs/devvault/data9/ic-sp-output.txt'']
Swirl Center Method: (fixed cg user-defined)
 Option[cg]
 Swirl Axis x[0]
 Swirl Axis y[1]
 Swirl Axis z[0]
 Tumble Axis x[0]
 Tumble Axis y[0]
 Tumble Axis z[1]
 Cross Tumble Axis x[1]
 Cross Tumble Axis y[0]
 Cross Tumble Axis z[0]
```

If you select **fixed** as the choice at **Swirl Center Method** then you will be prompted to enter the swirl center as follows:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
Swirl Center(x) (mm) [0]
Swirl Center(y) (mm) [0]
Swirl Center(z) (mm) [0]
```

If a swirl center method UDF has been compiled already and loaded into UDF then you can choose **user-defined** as the swirl center method option, in such a case the following is the sequence of prompts.

```
Swirl Center UDF[] swirl_udf::libudf
```

If the name of the UDF library is **libudf** then you can omit this and enter in the swirl center `UDF[]swirl_udf`, otherwise the name of the UDF followed by the UDF library name with symbol:: in between, should be entered.

By filling up the various entries that are needed in the In-Cylinder Output Controls Dialog Box (p. 5071) and pressing the **OK** button, the swirl and tumble calculations will be written at the chosen frequency to the chosen file while doing the solution run. Details of the quantities written to the file are as follows:

CA = Crank Angle

m = Mass of the entire fluid contained in the selected cell zones

L = Angular momentum vector of fluid mass contained in selected cell zones with respect to the swirl center

$|\vec{L}|$ = Magnitude of angular momentum of fluid

$\vec{sa}$ = Swirl Axis

$\vec{ta}$ = Tumble Axis

$\vec{cta}$ = Cross Tumble Axis

I $_{sa}$ = Moment of inertia of the fluid mass about Swirl axis

I $_{ta}$ = Moment of inertia of the fluid mass about Tumble Axis

I $_{cta}$ = Moment of inertia of the fluid mass about Cross Tumble Axis

$\cdot$ = Dot product between two vectors

Altogether, the previous quantities are combined to yield eight columns of data in the output file, as shown in the figure that follows:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

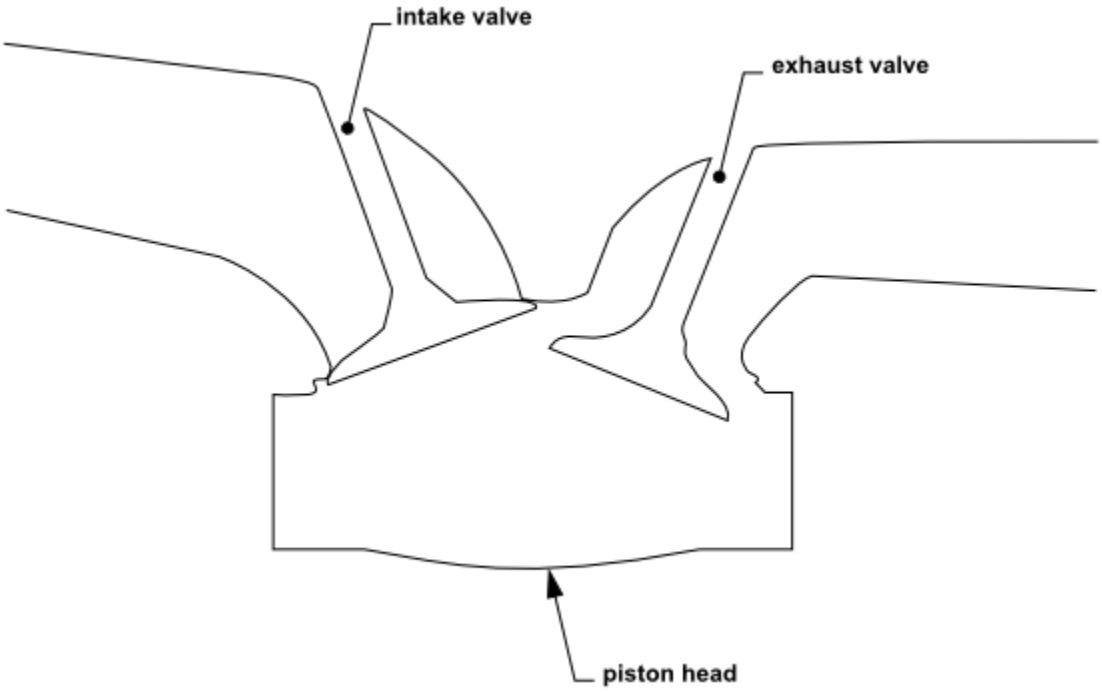
12.6.4.1. Using the In-Cylinder Option

This section describes the problem setup procedure for an in-cylinder dynamic mesh simulation.

12.6.4.1.1. Overview

Consider the 2D in-cylinder example shown in Figure 12.56: A 2D In-Cylinder Geometry (p. 1842) for a typical pent-roof engine.

Figure 12.56: A 2D In-Cylinder Geometry



In setting up the dynamic mesh model for an in-cylinder problem, you must consider the following issues:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- how to provide the proper mesh topology for the volume mesh update methods (smoothing, dynamic layering, and local or zonal remeshing)
- how to define the motion attributes and geometry for the valve and piston surfaces
- how to address the opening and closing of the intake and exhaust valves
- how to specify the sequence of events that controls the in-cylinder simulation

12.6.4.1.2. Defining the Mesh Topology

Ansys Fluent requires that you provide an initial volume mesh with the appropriate mesh topology such that the various mesh update methods described in Dynamic Mesh Update Methods (p. 1784) can be used to automatically update the dynamic mesh. However, Ansys Fluent does not require you to set up all in-cylinder problems using the same mesh topology. When you generate the mesh for your in-cylinder problem, you must consider the various mesh regions that you can identify as moving, deforming, or stationary, and generate these mesh regions with the appropriate cell shape.

The mesh topology for the example problem in Figure 12.56: A 2D In-Cylinder Geometry (p. 1842) is shown in Figure 12.57: Mesh Topology Showing the Various Mesh Regions (p. 1843), and the corresponding volume mesh is shown in Figure 12.58: Mesh Associated With the Chosen Topology (p. 1844).

Figure 12.57: Mesh Topology Showing the Various Mesh Regions

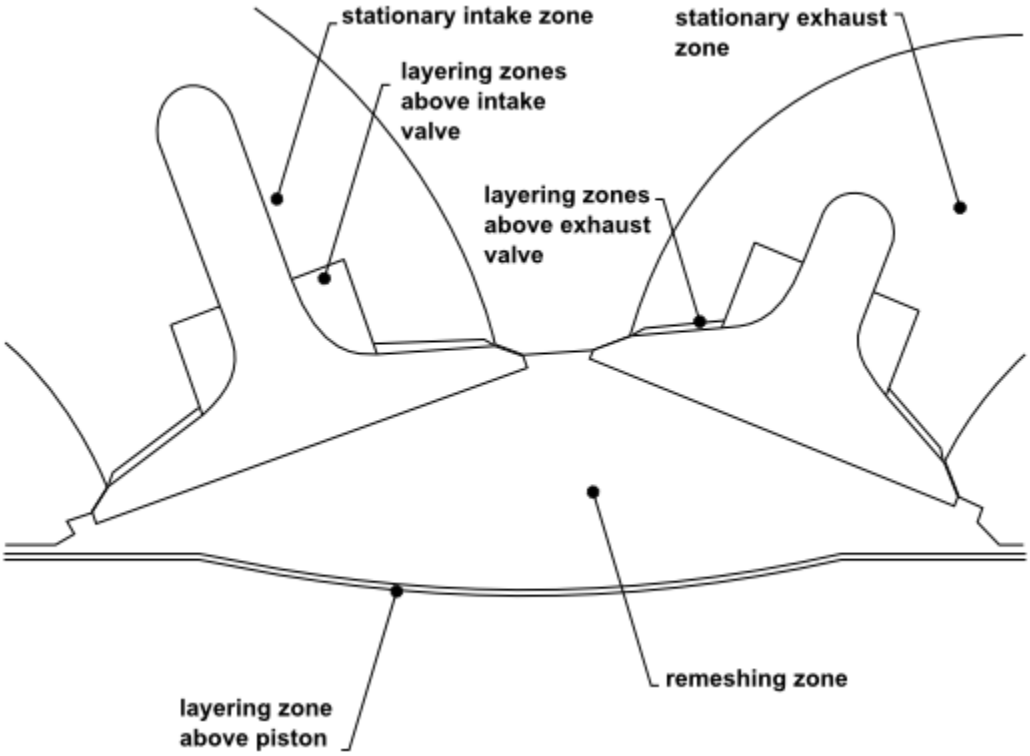


Figure 12.58: Mesh Associated With the Chosen Topology

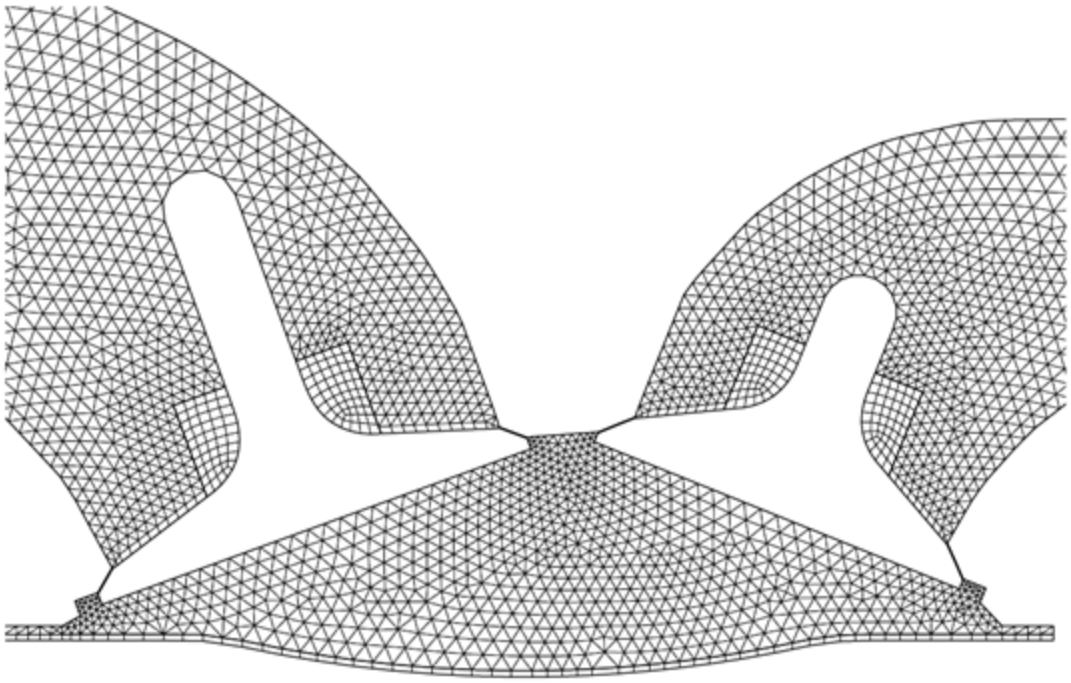


Because of the rectilinear motion of the moving surfaces, you can use dynamic layering zones to represent the mesh regions swept out by the moving surfaces. These regions are the regions above the top surfaces of the intake and exhaust valves and above the piston head surface, and must be meshed with prismatic cells that are quadrilateral in 2D or polyhedral, hexahedral, or wedge cells in 3D (as required by the dynamic layering method).

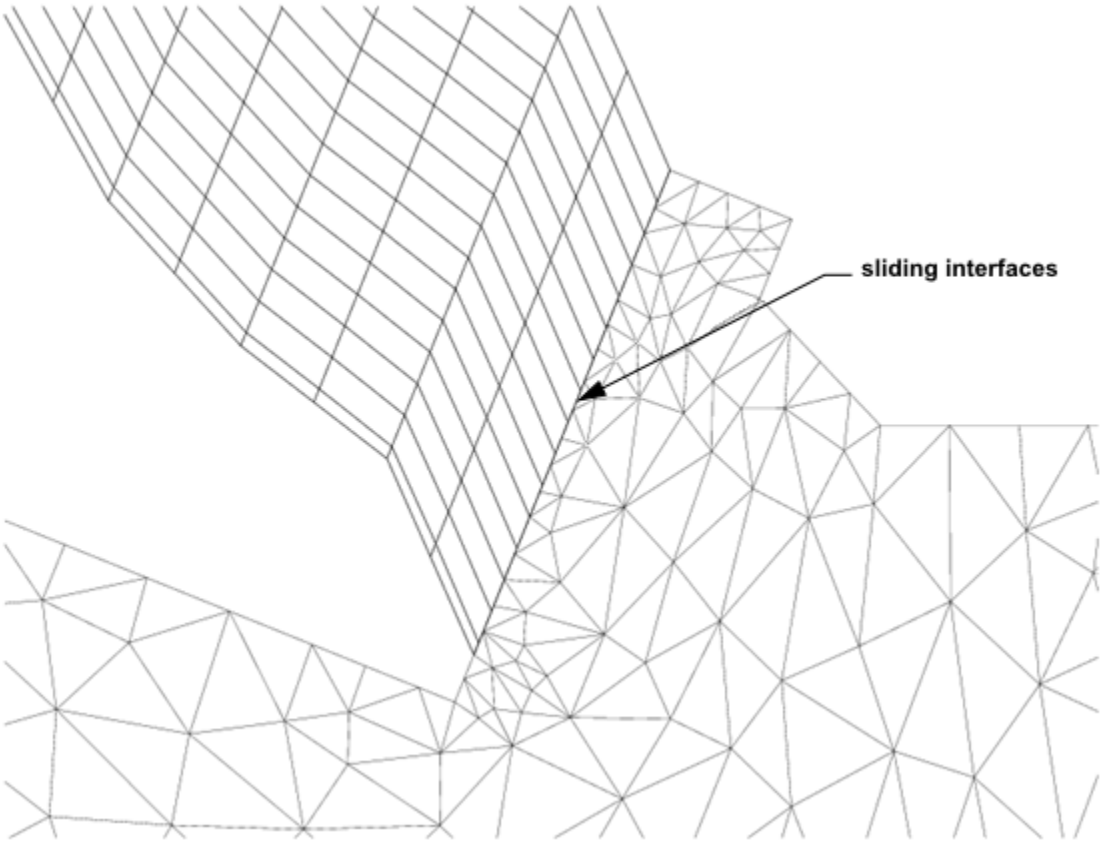
For the chamber region, you must define a remeshing zone (triangular cells) to accommodate the various positions of the valves in the course of the simulation. In this region, the motion of the boundaries (valves and piston surfaces) is propagated to the interior nodes through smoothing. If the cell quality violates any of the remeshing criteria that you have specified, Ansys Fluent will automatically agglomerate these cells and remesh them. Furthermore, Ansys Fluent will also remesh the deforming faces (based on the minimum and maximum length scale that you have specified) on the cylinder walls as well as those on the sliding interfaces used to connect the chamber cell zone to the layering zones above the valve surfaces.

For the intake and exhaust port regions, you can use either triangular or quadrilateral cell zones because these zones are not moving or deforming. Ansys Fluent will automatically mark these regions as stationary zones and will not apply any mesh motion method on these cell zones.

The dynamic layering regions above the piston and valves are conformal with the adjacent cell zone in the chamber and ports, respectively, so you do not have to use sliding interfaces to connect these cell zones together. However, you must use sliding interfaces to connect the dynamic layering regions above the valves and the remeshing region in the chamber. This is shown in Figure 12.59: The Use of Sliding Interfaces to Connect the Exhaust Valve Layering Zone to the Remeshing Zone (p. 1845) with the exhaust valve almost at full extension. Notice that cells on the chamber side of the interface zone are remeshed (that is, split or merged) as the interface zone opens and closes because of the motion of the exhaust valve.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.59: The Use of Sliding Interfaces to Connect the Exhaust Valve Layering Zone to the Remeshing Zone



12.6.4.1.3. Defining Motion/Geometry Attributes of Mesh Zones

As the piston moves down from the TDC to the BDC position, you must expand the remeshing region such that it can accommodate the valves when they are fully extended. To accomplish this, you must specify the dynamic layering zone adjacent to the piston surface to move with the piston until some specified distance from the TDC position. Beyond this cutoff distance, the motion of the layering zone is stopped and the piston wall is allowed to continue to the BDC position. Because there is relative motion between the piston head surface and the now non-moving dynamic layering zone, cell layers will be added when the ideal layer height criteria is violated. Figure 12.60: Mesh Sequence 1 (p. 1846) to Figure 12.65: Mesh Sequence 6 (p. 1848) show the sequence of meshes before and after the onset of cell layering when the motion in the layering zone above the piston surface is stopped (shown with $\Delta\theta = 5°$).

Figure 12.64: Mesh Sequence 5

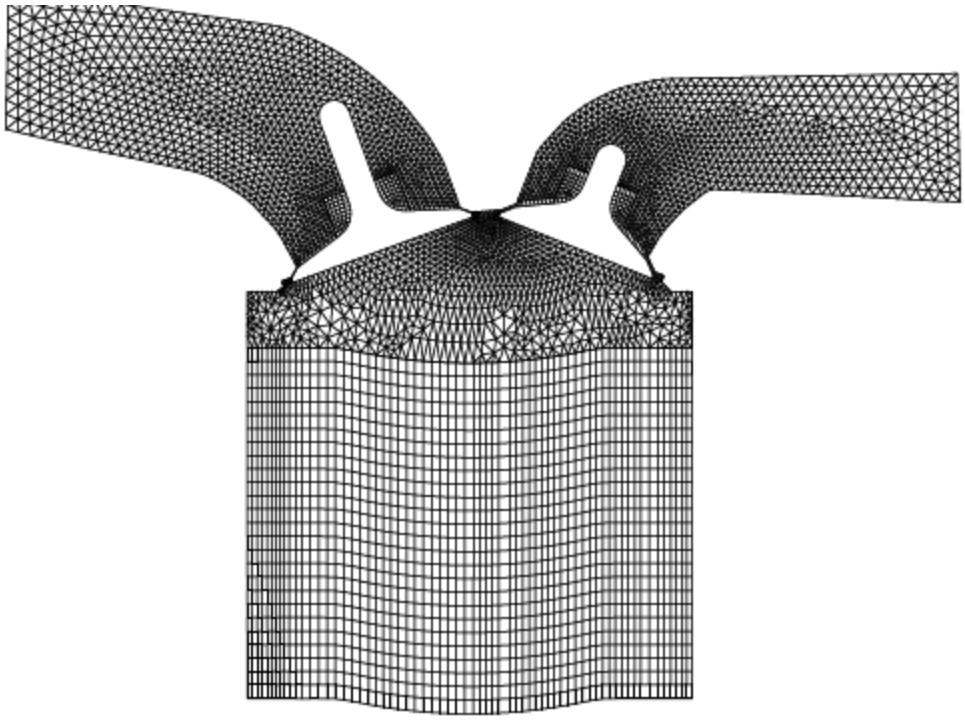

Figure 12.65: Mesh Sequence 6

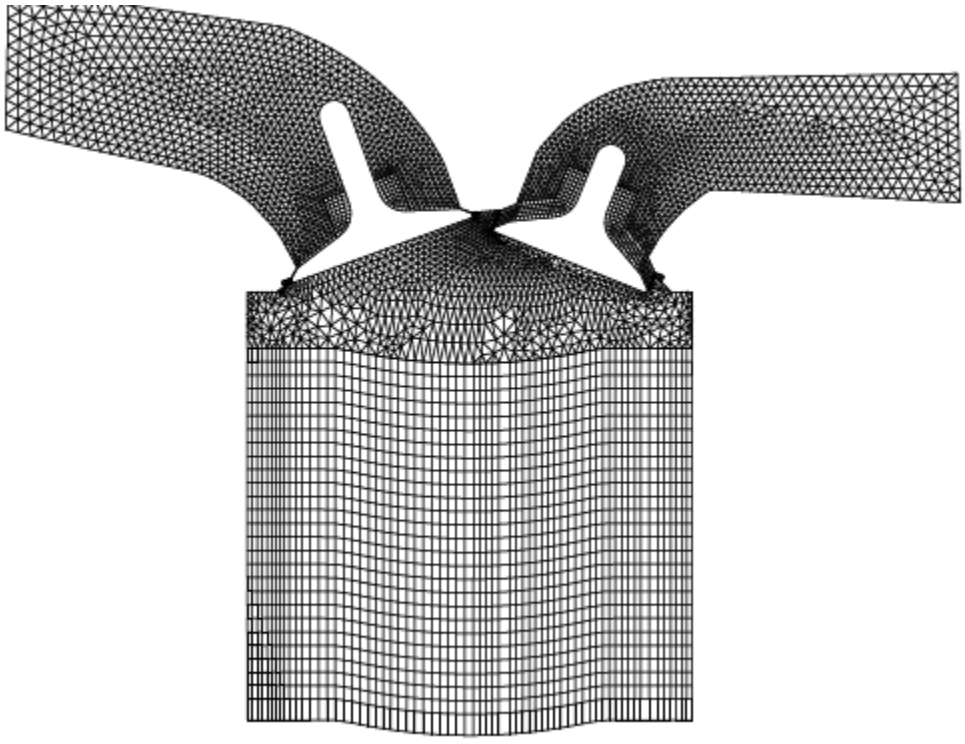
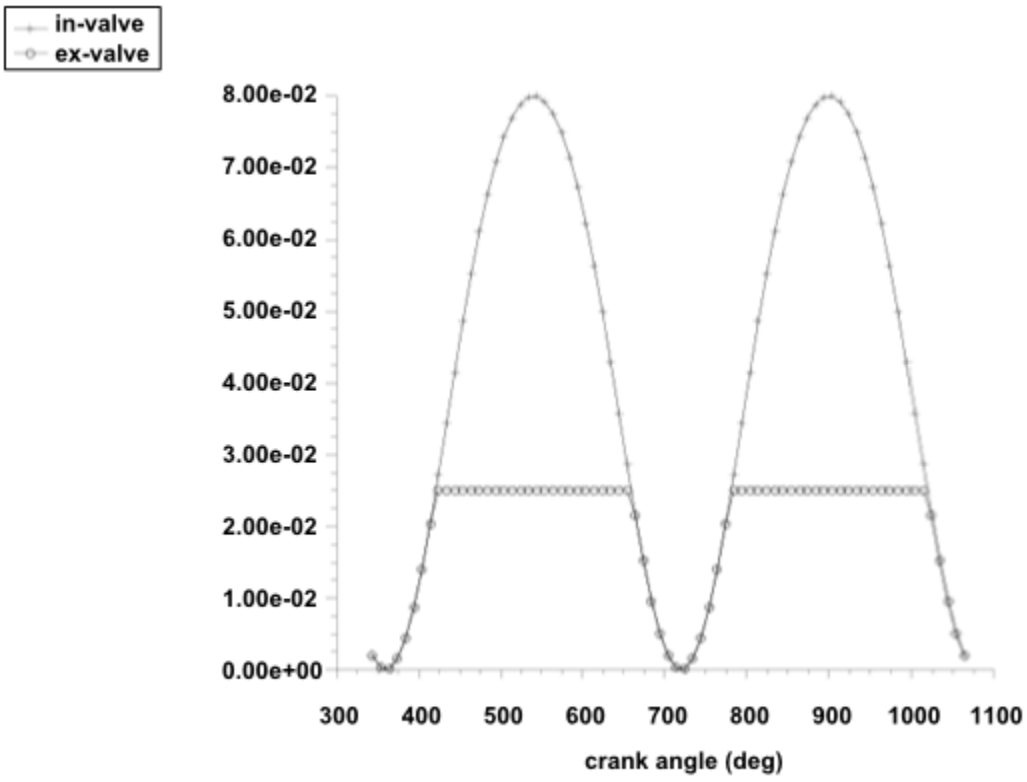


Ansys Fluent provides built-in functions to handle the full piston motion and the limited piston motion for the dynamic layering zone above the piston surface. When you define the motion

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

attribute of the dynamic layering zone above the piston surface, you must use the limited piston motion function (**piston-limit** in the **Motion UDF/Profile** field in the Dynamic Mesh Zones Dialog Box (p. 5086)). Note that you must define the parameters used by these functions before you can use them. In the current example, the crank radius is 40 mm and the connecting rod length is 140 mm. The piston stroke cutoff is assumed to happen at 25 mm from TDC position. The lift as a function of crank angle between 344° and 1064° is shown in Figure 12.66: Piston Position (m) as a Function of Crank Angle (deg) (p. 1849) for both limited and full piston motion.

Figure 12.66: Piston Position (m) as a Function of Crank Angle (deg)



To define the motion of the valves, you must use profiles that describe the variation of valve lift with crank angle. Ansys Fluent expects certain profile fields to be used to define the lift and the crank angle. For example, consider the following simplified profile definition:

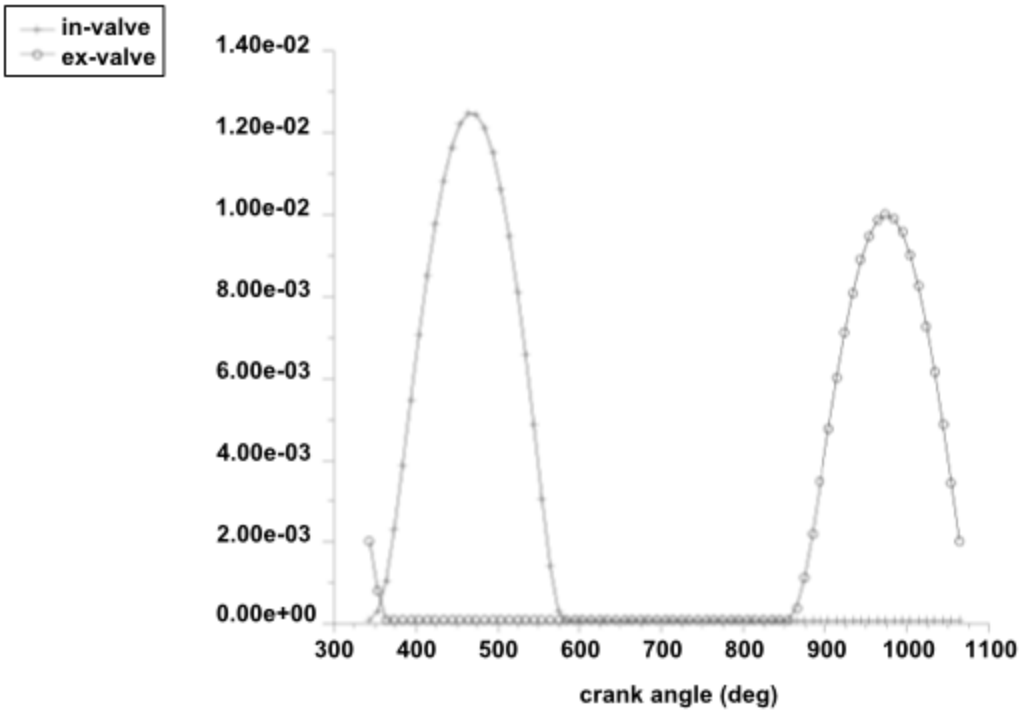
```
((ex-valve 5 point)
(angle 0  180 270 360  720)
(lift 0.05 0.05 1.8 0.05 0.05))

((in-valve 5 point)
(angle 0  355  440 540 720)
(lift 0.05 0.05 2.0 0.05 0.05))
```

Ansys Fluent expects the `angle` and `lift` fields to define the crank angle and lift variations, respectively. The angle must be specified in degrees and the lift values must be in meters. The actual valve lift profiles that you will use for the current example are shown in Figure 12.67: Intake and Exhaust Valve Lift (m) as a Function of Crank Angle (deg) (p. 1850). Notice that there is an overlapped period where both the intake and exhaust valves are open.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.67: Intake and Exhaust Valve Lift (m) as a Function of Crank Angle (deg)



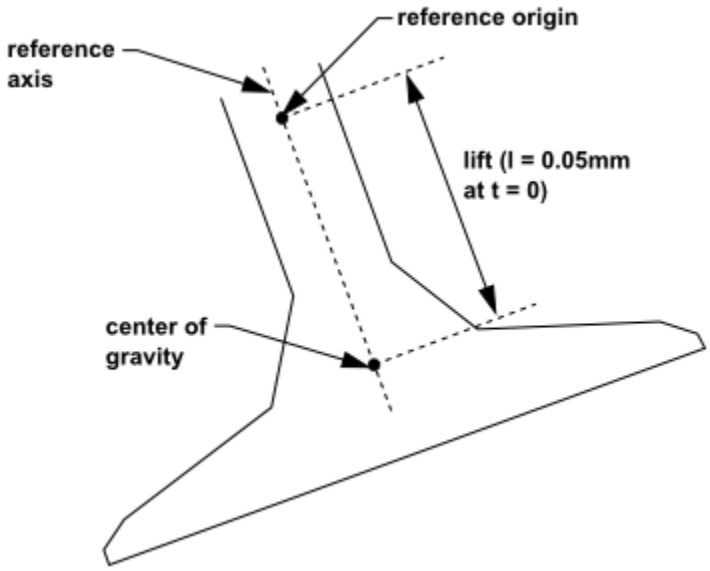
The valve lift profiles and the built-in functions will describe how each surface moves as a function of crank angle with respect to some reference point. For example, the valve lift is zero when the valve is fully closed and the valve lift is maximum when it is fully open. In order to move the surfaces, Ansys Fluent requires that you specify the direction of motion for each surface. Ansys Fluent will then update the "center of gravity" of each surface such that

$$\vec{x}=\vec{x}_{ref}-l\vec{e}_{axis} \tag{12.28}$$

where $\vec{x}_{ref}$ is some reference position, $\vec{e}_{axis}$ is the unit vector in the direction of motion, and l is either the valve or the piston distance with respect to the reference position $\vec{x}_{ref}$. Note that the unit vector of the direction of motion is specified to point in the negative direction. For example, the correct intake valve axis for this example is $\left(-0.3421, 0.9397\right)$, as shown in Figure 12.68: Definition of Valve Zone Attributes (Intake Valve) (p. 1851).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.68: Definition of Valve Zone Attributes (Intake Valve)



12.6.4.1.4. Defining Valve Opening and Closure

Ansys Fluent assumes that once you have set up the mesh topology, the mesh topology is unchanged throughout the entire simulation. Therefore, Ansys Fluent does not allow you to completely close the valves such that the cells between the valve and the valve seat become degenerate (flat cells) when these surfaces come in contact (removing these flat cells would require the creation of new boundary face zones). To prevent the collapse, you must define a minimum valve lift and Ansys Fluent will automatically stop the motion of the valve when the valve lift is smaller than the minimum valve lift value. The minimum valve lift value can be specified in the **In-Cylinder** tab of the Options Dialog Box (p. 5067). For the current example, a minimum valve lift value of 0.1 mm is assumed.

When the valve position is smaller than the minimum valve lift value, it is normal practice to assume that the valve is closed. The actual closing of the valves is accomplished by deleting the sliding interfaces that connect the chamber cell zone to the dynamic layering zones on the valves. The interface zones are then converted to walls to close off the "gaps" between the valves and the valve seats.

The valve opening is achieved by the reverse process. When the valve lift has reached beyond the minimum valve lift value, the valve is assumed to be open and you can redefine the sliding interfaces such that the chamber zone is now connected to the dynamic layering zones above the valves.

12.6.5. Six DOF Solver Settings

Ansys Fluent's six degrees of freedom (six DOF) solver computes external forces and moments (such as aerodynamic and gravitational forces and moments) on objects that undergo rigid body motion. These forces are computed by numerical integration of pressure and shear stress over the object's surfaces. Additional load forces can be added, such as injector forces, thrust (propulsive) forces, and moments produced by a coil spring. This technique, along with the Ansys Fluent solver and the use of dynamic meshes, can be readily applied to many useful applications, such as store separation [135] (p. 5662), [146] (p. 5663). Note that the objects may be composed of multiple zones.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To use the six degrees of freedom solver for your transient dynamic mesh simulation, perform the following steps:

1. Enable the **Six DOF** option in the **Options** group box of the Dynamic Mesh Task Page (p. 5057) (Figure 12.13: The Dynamic Mesh Task Page (p. 1783)) and click the **Settings...** button. The **Options** dialog box will open, where you can click the **Six DOF** tab (Figure 12.69: The Six DOF Tab of the Options Dialog Box (p. 1852)).

   Figure 12.69: The Six DOF Tab of the Options Dialog Box

   This tab allows you to perform the following actions:

   - You can create and manage sets of six DOF properties for rigid body motion by using the list and buttons under **Six DOF Properties**; otherwise, you will have to create one or more user-defined functions. See Setting Rigid Body Motion Attributes for the Six DOF Solver (p. 1853) for details.

   - You can specify the gravitational acceleration for the *x*, *y*, and *z* directions either in this dialog box, or in the **Operating Conditions** dialog box.

   - You can keep track of an object's motion history by enabling the **Write Motion History** option and entering a **File Name**. A single motion history file will be generated for each moving object, which can be used to display zone motion for postprocessing your results. Note that the file name you specify will be appended with the name of the set of six DOF properties / UDF, as

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

well as the extension `.6dof`; you can change the extension by specifying your own as part of the **File Name**.

2. If the mesh motion of your six DOF simulation depends on the fluid flow, it is beneficial to enable implicit mesh updating (as described in Implicit Update Settings (p. 1856)). If the implicit mesh update is not sufficient to stabilize the solver due to the fluid motion, solution stabilization may be necessary. The solution stabilization settings are set in the **Solver Options** tab of the **Dynamic Mesh Zones** dialog box for boundary zones (Solution Stabilization for Dynamic Mesh Boundary Zones (p. 1886)).

3. Define the rigid-body zone(s) that make up each moving object by using the Dynamic Mesh Zones Dialog Box (p. 5086), as described in Rigid Body Motion (p. 1874).

Setup → **Dynamic Mesh** → **Create/Edit...**

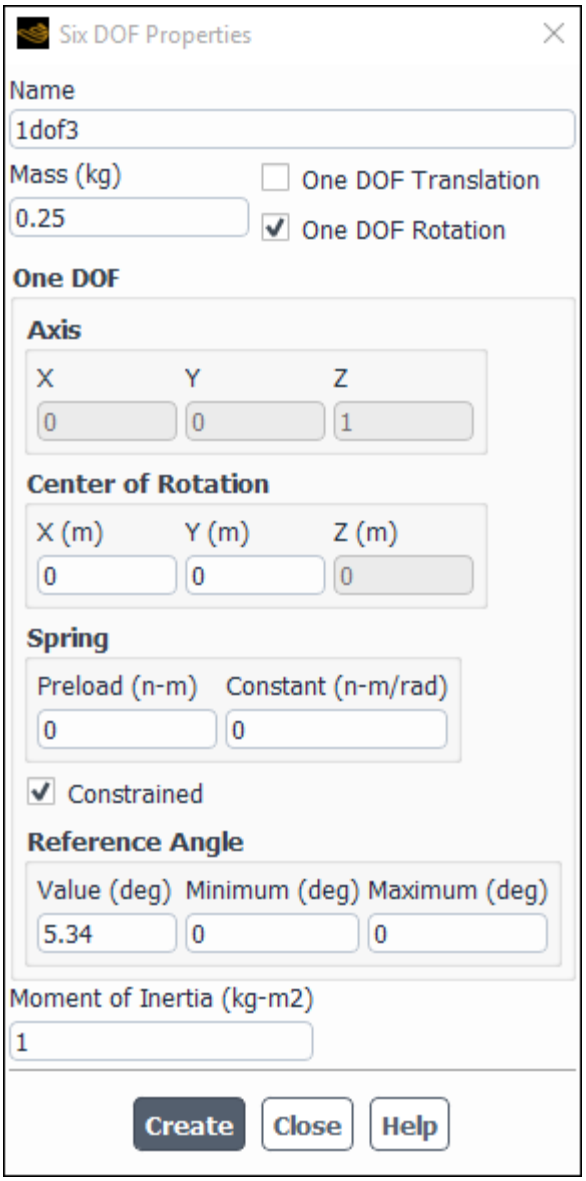
12.6.5.1. Setting Rigid Body Motion Attributes for the Six DOF Solver

As part of the six DOF solver settings, you must provide either a set of properties or a user-defined function (UDF) for each moving object, in order to define its overall mass, rotational inertia, constraints, loading from sources other than aerodynamics and gravity, and so on. Each object needs exactly one set of properties / UDF, regardless of how many zones make up the object. Note that if you have multiple identical objects, you can create an initial set of properties / UDF, and then make copies with unique names.

If the motion of the object is complex or if only half of the object is modeled using a symmetry zone, then you will need to use a UDF (see `DEFINE_SDOF_PROPERTIES` in the *Fluent Customization Manual* for the details); otherwise, it is easier to use a set of properties. Such sets are created using the **Six DOF Properties** dialog box, which is opened by clicking the **Create/Edit...** button in the **Six DOF** tab of the Options Dialog Box (p. 5067).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.70: The Six DOF Properties Dialog Box



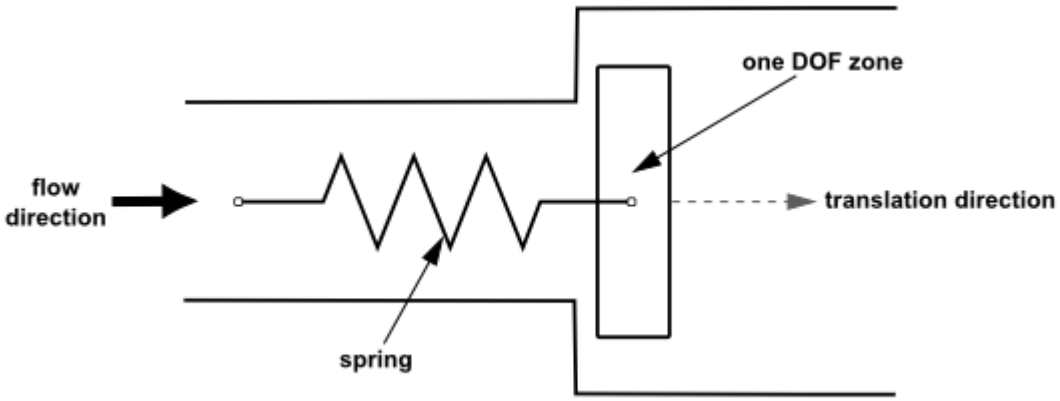
In the **Six DOF Properties** dialog box, you will need to provide a **Name** for the set of properties, define the other fields in the dialog box, and click **Create**.

For six DOF motion, the only other fields that must be defined are the **Mass** and the **Inertia Tensor** components. Note that the inertia tensor components are defined relative to the **Center of Gravity** and **Rigid Body Orientation** settings defined in the Dynamic Mesh Zones Dialog Box (p. 5086); the latter settings allow you to use a coordinate system that is local (rather than global), if that is more convenient.

If you want to specify that the dynamic object be limited to one DOF motion (that is, either a simple translation or a simple rotation), enable the **One DOF Translation** or **One DOF Rotation** option and define the settings in the **One DOF** group box. The following figure shows an example of a one DOF translation:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.71: A Check Valve with One DOF Translation



Note the following about one DOF motion settings:

- For rotation, you will define the **Mass** of the dynamic object, in case the **Center of Rotation** is different than the **Center of Gravity** defined in the Dynamic Mesh Zones Dialog Box (p. 5086) (which may be the case in a swinging pendulum, for example), so that Fluent can calculate the moment due to gravity.

  For rotation, you will also define the **Moment of Inertia**, as calculated around the **Center of Rotation** and **Axis**. Fluent calculates the moment of fluid forces about the **Center of Rotation**. Note that this definition of the **Moment of Inertia** is different from a six DOF case that does not use **One DOF Rotation**, where you would calculate the **Inertia Tensor** relative to the **Center of Gravity** and **Rigid Body Orientation** settings defined in the Dynamic Mesh Zones Dialog Box (p. 5086), as noted previously.

- For 2D cases with rotation, the axis will be either the positive or negative *z* direction, depending on the sign of the value you enter for **Z** in the **Axis** group box.

- You have the option of defining a Hooke's law **Spring** that exerts forces / torques on the dynamic object. It is a compression / extension spring for translations, and it is a torsion spring for rotations.

  For example: for a translation, the specified **Constant** will be multiplied by the distance of the dynamic object from its initial location. This force will be combined with a **Preload** value that is constantly applied to the dynamic object, in order to produce the net spring loading. Note that the **Preload** can be a positive or negative value, and is defined relative to the **Direction**.

- You can limit the range of motion of the dynamic object by enabling the **Constrained** option and defining the settings in the **Reference Point** group box (for translation) or the **Reference Angle** group box (for rotation).

  For example: for a translation, you could enter 2 inches for the **Location**, in order to assign a coordinate value to a point located on the dynamic object in its initial position. Then you would define the range of motion allowed relative to that coordinate: you would enter `1.2` and 2 inches for the **Minimum** and **Maximum**, respectively, if you wanted the object to only be allowed to move .8 inches in the direction opposite to the **Direction** vector. The value of the **Location** is arbitrary, and allows you to define the range using values that are most convenient for your problem.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The initial position / orientation of the object (which is used to calculate the spring loading and/or range of motion) is established when you create the dynamic zone(s) using the Dynamic Mesh Zones Dialog Box (p. 5086).

12.6.6. Implicit Update Settings

For transient problems, you can enable implicit mesh updating when you want to have the dynamic mesh updated during a time step (as opposed to just at the beginning of a time step). This capability is beneficial only for applications in which the mesh motion depends on the flow field (for example, cases that use the six DOF solver or involve fluid-structure interaction). For such applications, having the mesh motion updated within the time step based on the converging flow solution results in a stronger coupling between the flow solution and the mesh motion, and leads to a more robust solver run. Implicit mesh updating allows you to run simulations that otherwise could not be solved or would require an unreasonably small time step size.

Note that implicit mesh updating cannot be used with the following:

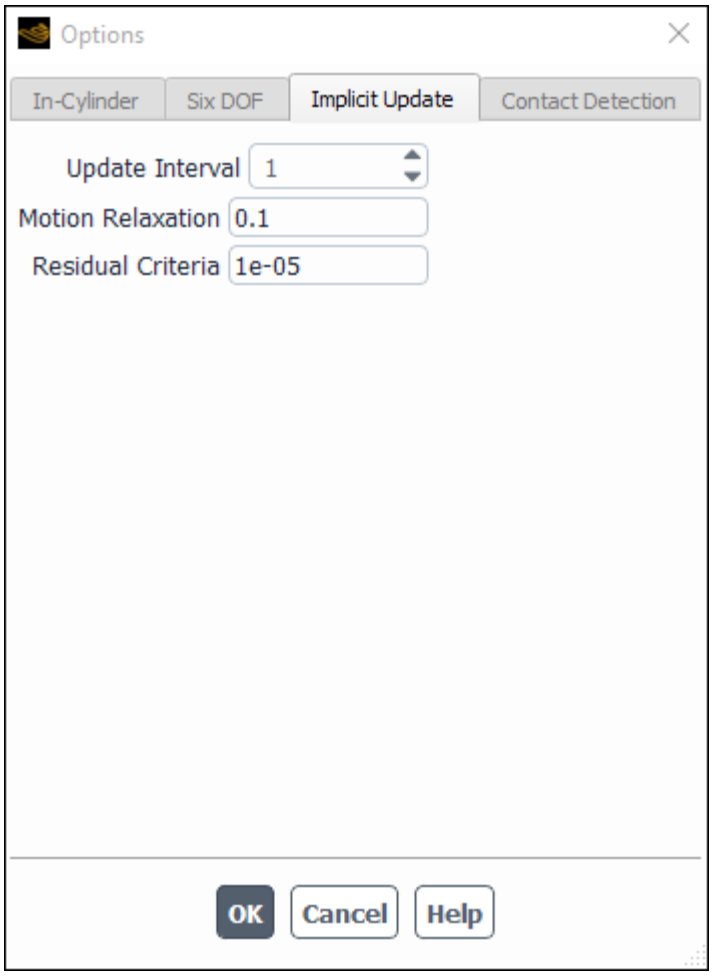
- the density-based solver when **Explicit** is selected from the **Transient Formulation** drop-down menu in the **Solution Methods** task page
- steady-state solutions
- in-cylinder applications

To enable implicit mesh updating, perform the following steps:

1. Enable **Implicit Update** in the **Options** group box of the Dynamic Mesh Task Page (p. 5057) (Figure 12.13: The Dynamic Mesh Task Page (p. 1783)).
2. Click the **Settings...** button to open the Options Dialog Box (p. 5067).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.72: The Implicit Update Tab of the Options Dialog Box



Click the **Implicit Update** tab and enter values for the settings.

a. Enter a value for **Update Interval**, in order to specify the frequency in iterations at which the mesh will be updated within a time step.

b. Enter a value (within the range of 0 to 1) for **Motion Relaxation**, in order to define the relaxation of the motion (that is, displacement of the nodes) during the mesh update. The relaxation of the displacements is defined by the following equation:

$$x_k = \omega(x_{computed,k}) + (1-\omega)x_{k-1} \tag{12.29}$$

where x_k is the node position at iteration k (within a time step), $x_{computed,k}$ is the computed node position (based on the flow field), and ω is the motion relaxation.

Note:

The nodal positions returned from the UDF / profile will *not* be relaxed according to Equation 12.29 (p. 1857) if you select **User-Defined** from the **Type** list when setting up your dynamic mesh zones in the Dynamic Mesh Zones Dialog Box (p. 5086).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

c. Enter a value for **Residual Criteria**, in order to set the relative residual threshold that is used to check the motion convergence. The residual criteria is applied to a relative residual. Ansys Fluent scales the difference between the motion in iteration k and iteration $k-1$ by the motion computed at the beginning of the time step. If this relative motion difference is smaller than the residual criteria, the mesh motion is considered converged.

3. If you are using a UDF to compute the motion, make sure that the UDF uses the current flow field during each call to compute the motion (that is, no previously stored information should be used). This is necessary, as the UDF will be called each time the mesh is updated — which can be several times within a time step, depending on what you entered for the **Update Interval**.

4. After you run the simulation, make sure that the motion (and consequently, the solution) is properly converged. If the motion requires more iterations to converge than the flow field, a warning will be displayed in the console during the iteration process. Note that the maximum number of iterations per time step (defined in the **Run Calculation** task page) is respected by the mesh motion convergence check.

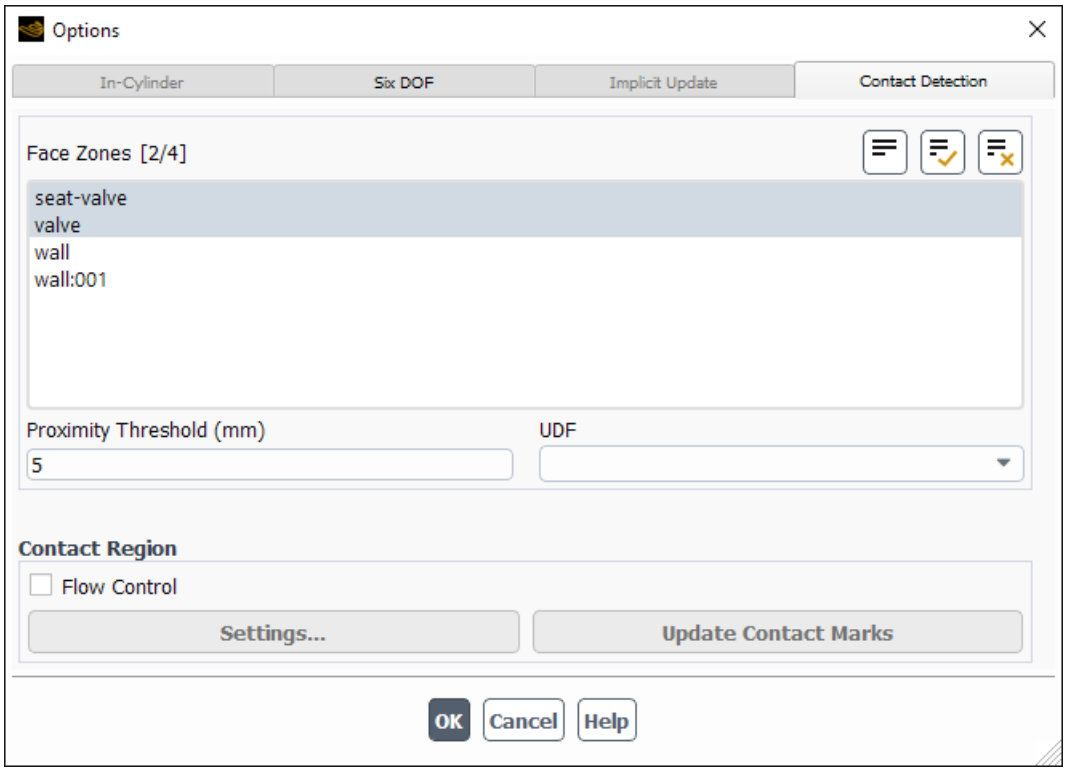
12.6.7. Contact Detection Settings

Contact detection is used to detect if the computed mesh motion will result in contact of a moving surface with other surrounding surfaces. If there is contact within a specified tolerance, then the mesh motion of the moving zone can be constrained using nodal contact information within user-defined functions (See Example 2 under DEFINE_CONTACT in the Fluent Customization Manual) and/or the flow can be controlled in the contact region.

To enable contact detection in your dynamic mesh simulation, select the **Contact Detection** check box in the **Options** group of the **Dynamic Mesh** task page. Click the **Settings...** button to open the **Options** dialog box and select the **Contact Detection** tab (see Figure 12.73: The Contact Detection Tab of the Options Dialog Box (p. 1859)).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.73: The Contact Detection Tab of the Options Dialog Box



You can select the face zones that will be involved in the contact detection process from the **Face Zones** list. While all eligible face zones in the **Face Zones** list are selected by default, you can choose to exclude certain zones for efficiency. Only walls and dynamic zones of type **Rigid Body** or **User-Defined** can be selected for contact detection.

From the **UDF** drop-down list, you can specify a user-defined function that will be invoked when contact has been detected. For more information about contact UDFs, see `DEFINE_CONTACT` in the Fluent Customization Manual.

You must specify a **Proximity Threshold** value in order to enable the contact detection process. When the distance between face zones falls below this threshold value, the UDF specified in the **UDF** drop-down list is invoked.

You can also apply flow control in the contact region. Flow control is applied to the cells that lie within the **Proximity Threshold** distance of the specified face zones. There are two methods available for flow control: one based on contact zones (Flow Control Using Contact Zones (p. 1860)), and another based on contact marks (Flow Control Using Contact Marks (p. 1860)). To use one of these methods, enable the **Flow Control** option in the **Contact Region** group box and click the **Settings...** button to open the **Flow Control Settings** dialog box, where you can complete the setup (as described in the following sections).

Note:

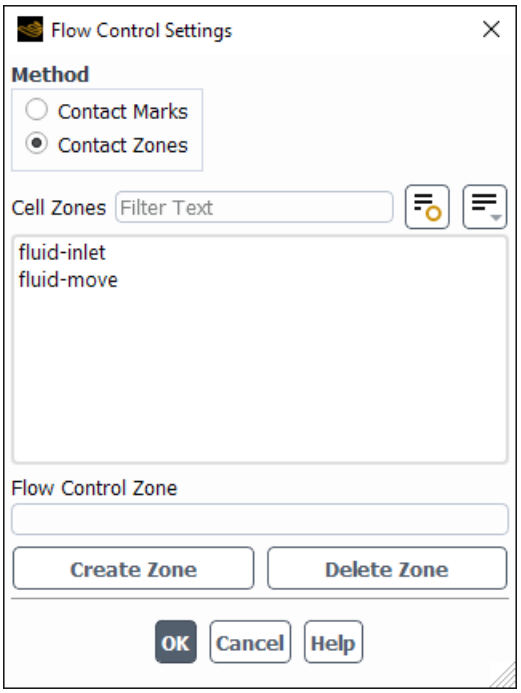
When simulating the complete blockage of flow between moving surfaces, it is recommended that you use the gap model rather than the **Flow Control** option (and the two are not compatible with each other). For details, see Controlling Flow in Narrow Gaps for Valves and Pumps (p. 1211).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12.6.7.1. Flow Control Using Contact Zones

You can select **Contact Zones** from the **Method** list in the **Flow Control Settings** dialog box. The **Contact Zones** method for controlling flow allows you to modify the flow in the contact region by creating a separate cell zone containing the marked cells. The flow in this cell zone may be controlled using the available cell zone conditions. By default, the zone is defined to have porous resistance. This method is fully compatible with all solver options.

Figure 12.74: The Flow Control Settings Dialog Box with Contact Zones



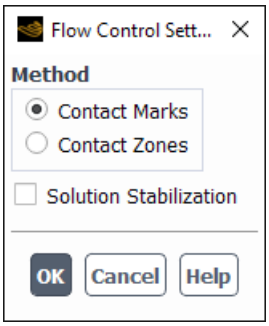
To complete the setup, you must create one or more flow control zones. Select a fluid cell zone from the **Cell Zones** list, specify a new name in the **Flow Control Zone** text box, and click the **Create Zone** button. A new cell zone will be created that is based on the selection from the **Cell Zones** list, only with the **Porous Zone** option enabled. The **Fluids** dialog box will open for this new zone, allowing you to revise physical properties (for example, inertial and/or viscous porous resistance) so that it better represents the restricted flow. During the simulation, after cells in the contact region have been separated into new zones, the physical properties specified in the respective flow control zone are copied to the newly separated cell zone.

12.6.7.2. Flow Control Using Contact Marks

You can select **Contact Marks** from the **Method** list in the **Flow Control Settings** dialog box. The **Contact Marks** method applies a zero mass flux numerical boundary condition on the boundary of the marked contact region that blocks the flow.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.75: The Flow Control Settings Dialog Box with Contact Marks



When the **Contact Marks** method is selected, you have the option of enabling **Solution Stabilization** to improve the stability of the simulation. **Solution Stabilization** applies solution control to stabilize the solution in the vicinity of the contact region during contact engagement, evolution, and disengagement. **Solution Stabilization** involves additional iterations within the time step, during which solution convergence checks are suspended.

Note that the following limitations apply when using the **Contact Marks** method:

- It is limited to the pressure-based solver.
- The use of the **Green-Gauss Node Based** gradient method and/or the **QUICK** discretization scheme is not supported.
- The Non-Iterative Time Advancement (NITA) scheme is not supported.
- Boundary zones of type **outflow** are not recommended.

12.6.7.2.1. Selecting Parameters for Flow Control

For transient flows with moving face zones, the marked contact region is not fixed and could change during every time step when there is mesh motion. With the **Contact Zones** method, this involves deletion and recreation of the cell zone used to apply flow control; this is a computationally expensive operation. Furthermore, while the porous sources are effective in providing resistance to flow, they do not achieve complete flow blockage (which may desirable, for example, in the case of modeling the closing of a valve). Consequently, the **Contact Zones** method may be the recommended method for flow control only under the following conditions: complete flow blocking is not required; the flexibility of cell zone conditions to modify the flow is sufficient; and the contact region is not undergoing rapid changes.

The **Contact Marks** method applies a numerical zero mass flux boundary condition at the boundary faces of the region marked for contact, such that the cells in the contact region no longer participate in the solution. There are a few key advantages of this method that are important to note:

- Marking is computationally more efficient than zone separation.
- The flow is completely blocked at the contact region boundary and there is no flow leakage. This is a realistic flow condition for valves in the closed position.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- It can reduce computational cost in narrow gaps by reducing the need for a high cell count to resolve high solution gradients in the flow between walls in close proximity (for example, a valve opening and closing).
- It can avoid the difficulties of meshing and/or remeshing in narrow passages, especially with moving deforming meshes.

While there are clear advantages, there are some important considerations when using the **Contact Marks** method. The imposition of the zero mass flux condition on arbitrary interior boundary faces can introduce large gradients in the flow in the vicinity of the contact region boundary. Here, **Solution Stabilization** is recommended for cases where the engagement, evolution, and disengagement of contact can be rather abrupt and the maintaining of solver stability poses a challenge. The use of high order term relaxation and a reduced time step size (for compressible flows) may also be beneficial for improving convergence behavior with the **Contact Marks** method.

12.6.7.2.2. Modifying and Displaying Contact Cell Marks

The extents of the contact region are determined by the definition of the proximity threshold distance, the selection of face zones participating in contact detection, and the local mesh size, and this in turn influences the final solution. Contact marks are established during initialization if the proximity threshold distance is satisfied for both steady-state and transient simulations. For transient simulations, subsequently contact marks are updated every time step.

Note that the **Update Contact Marks** button is available in the **Options** dialog box when the **Contact Marks** method is selected for flow control. This provides the ability to update the contact marks immediately without having to reinitialize the solution. That way, you can instantly modify the contact region based on varying the parameters of the contact detection. You can remove or introduce flow blocking after obtaining a solution initially with or without flow blocking, respectively. This option is particularly useful in the process of generating realistic initial conditions for modeling transient flows using flow blocking based on **Contact Marks**.

By default, the contact cell marks are not rendered. You can render the contact cell marks by entering the following text command:

`define` → `dynamic-mesh` → `controls` → `contact-parameters` → `render-contact-cells?`

Then you can display the marked cells by selecting **Cell Info...** and **Contact Cell Mark** from the **Contours of** drop-down lists, and postprocess other field variables on those cells. Note that only cell values are available for **Contact Cell Mark**, so you must ensure that the **Node Values** option is disabled in the **Contours** dialog box.

12.6.8. Defining Dynamic Mesh Events

If you are simulating a transient flow, you can use the events in Ansys Fluent to control the timing of specific events during the course of the simulation. With in-cylinder flows for example, you may want to open the exhaust valve (represented by a pair of deforming sliding interfaces) by creating an event to create the sliding interfaces at some crank angle. You can also use dynamic mesh events to control when to suspend the motion of a face or cell zone by creating the appropriate events based on the crank angle or time. Note that in-cylinder flows are crank angle-based, whereas all other flows are time-based.

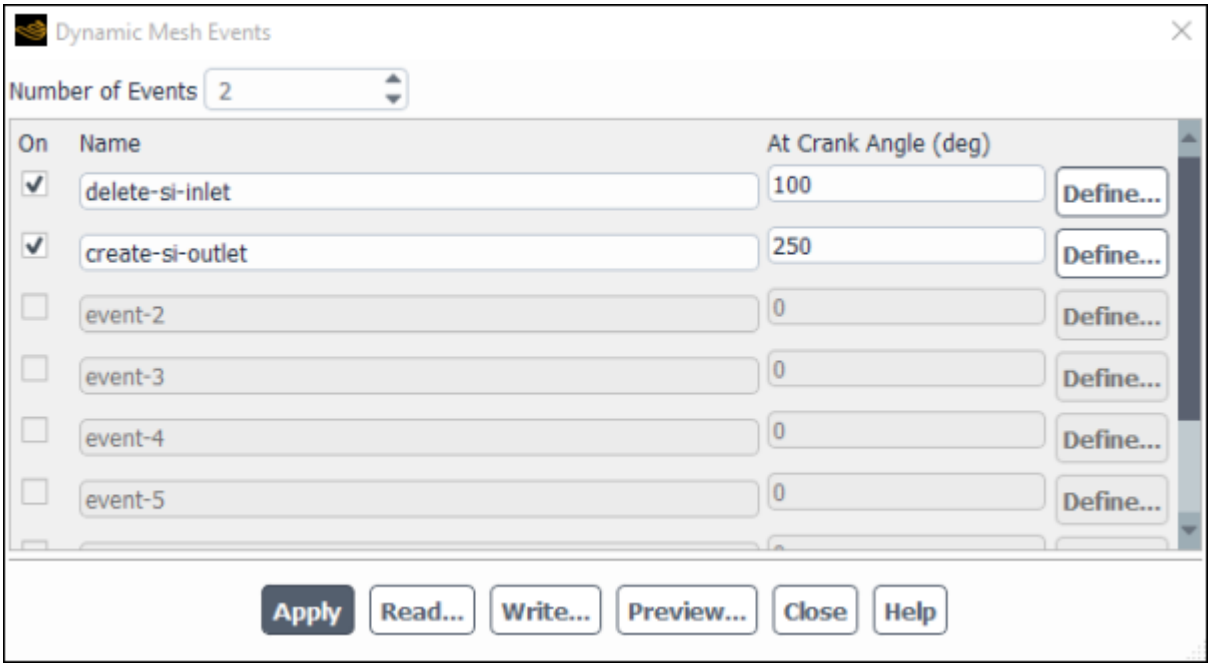
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12.6.8.1. Procedure for Defining Events

You can define the events using the Dynamic Mesh Events Dialog Box (p. 5081) (Figure 12.76: The Dynamic Mesh Events Dialog Box (p. 1863)).

Setup → Dynamic Mesh → Events...

Figure 12.76: The Dynamic Mesh Events Dialog Box



The procedure for defining events is as follows:
